*Diagnosis*.—[It has been compared to, and probably sometimes, confounded with, scirrhus ulcerations of these parts; but the features by which it may readily be distinguished from such affections, are the following:—1. Cancerous disease of

<sup>a</sup> From "*vitulus*," a calf.

<sup>b</sup> "*Vitiligo* of the dropsical and the pregnant."

<sup>c</sup> "*Library of Medicine*," Volume I; Pages 424 and 425.

<sup>e</sup> From "*scrotum*," a skin.

<sup>f</sup> With respect to cancer of the skin, I need say nothing; because I have already spoken of it, when treating of structural diseases at large. (See Page 195.) The particular treatment of cancer, falls within the province of the surgeon.

<sup>g</sup> So called from its resemblance to a wolf (lupus) in the ravages which it makes.

these parts usually occurs first on the lower lip. 2. The uneasiness belonging to it is, in no case, described to be worse than are comprehended under the general designations of "heat," "itching," "tingling," or "smarting;" while scirrhus ulceration is accompanied by severe darting pains. 3. Diseased enlargement of the contiguous glands, does not often make its appearance in its train, even though the disease has existed for years; which is not the case with cancer. 4. The surface of the sore is never occupied by fungous granulations, or has thickened and hardened or everted edges; but retains its peculiar character to the last.<sup>a</sup>

*Treatment.*—Some cases have been cured, it is said, by the application of caustics, and particularly arsenic; but there is no rule for the treatment; and I believe, in a great number of cases, the disease resists all means.

## SECTION II.—ELEPHANTIASIS.

The next disease which I shall briefly notice, is one of very rare occurrence in this country;—so that I have seen only two or three instances of it. I refer to "elephantiasis." It receives its name from the skin becoming as rough and hard as the back of an elephant. It has been termed "the elephantiasis of the *Greeks*;"—to distinguish it from another form, which is local.<sup>b</sup>

*Characters.*—In this disease the features become extremely altered. The lips are very thick; and the whole of the face, and great part of the body, are beset with hard tubercles;—so that a person could not be recognized, by those who knew him previously to the appearance of the disease. The face is particularly rough. It is considered by Rayer to be a chronic inflammation; but we may either regard it as such, or as an organic disease of the skin. It is characterized by numerous independent tubercles of a livid colour; particularly developed on the face and ears, the upper and lower extremities, and likewise on the arch of the palate. The tubercles terminate, either by resolution, or by small ulcerations; which seldom extend in depth or breadth. They are covered by adherent crusts, under which a cicatrix is formed. It may occur in any part of the body; but, like lupus, it attacks the face much more than other parts. It has been said, by a great many writers, that the sexual desire becomes insatiable in this affection. Others, however, deny this; and not only so, but they go to the other extreme, and say it is extinguished.

[A kind of dry gangrene pervades the fingers and toes, which are generally eaten away, and drop off at the first phalanges; these sores then generally cicatrize, without any rete mucosum; and the next joint becomes invaded, by a renewal of the ulcerative process. It is singular to observe that, notwithstanding these extensive sores, the patients can wear hard shoes, which are saturated with the sanious ichor that exudes from these ulcerated surfaces. The disease progressively advances;—eating through the ankles and wrists; and performing slow, but certain and successive dismemberment;—every revolving year bearing some trophy of this tardy, but gradual march of death; till, at last, the vitals become affected. During all this time, a sleepy inertness overpowers the mind, and "seems to be numb and almost annihilate every faculty, as well of the soul as of the body; leaving only sufficient sense and activity to crawl through the routine of existence."

In the last stages of this complaint, the flesh gapes with long sores; the mouth, nose, and brain become exposed to its ravages; and death, at length, terminates this loathsome existence. The patient is usually cut off by the supervention of diarrhœa. It is astonishing, however, to witness how long the victim lingers;—from twelve to twenty years being no uncommon duration. During the greater part of this period, he has a good, and even voracious appetite; and moves about from village to village.<sup>c</sup>

*Causes.*—[It is not contagious, but appears to be hereditary; though not neces-

<sup>b</sup> "Barbadoes-leg," or "elephantiasis of the *Arabs*." See Page 471.

<sup>c</sup> Brett's "Practical Essay on the Surgical Diseases of India;" Page 164.

sarily so. M. Bielt lately attended a lady, from the West Indies, affected with tuberculous leprosy in a very severe degree; and who had been delivered of several children since the disease first appeared. These children, who are now of a certain age, all enjoy excellent health; and do not show the least symptoms of Greek elephantiasis. This disease attacks both sexes equally; and appears at all periods of life, but less frequently in elderly persons. The cases seen in Europe generally come from the West Indies and other colonies. We have seen it in a young Portuguese; who, according to his statement, had never left Portugal before the appearance of the disease. In the colonies, damp dwellings, malaria, and unwholesome food, especially pork, often appear to be exciting causes. To these may be added, over-working, the too free use of spirits, and especially depressing moral affections.

*Diagnosis.*—In the commencement, the erythematous patches may be considered as symptoms of a disease far less fearful than *lepra tuberculosa*; and often, for a time, mislead. The impaired or total loss of sensibility in these points of the integuments, their dusky red hue, soft feel, and the circumstance of the patient having previously inhabited a tropical climate, may assist the diagnosis; the mistake would, however, be only that of not foreseeing the disease that is about to occur. At a more advanced stage, we conceive an error to be almost impossible;—if we compare the symptoms of the occasional tubercle of lupus, or those connected with a syphilitic origin, of mollusca, and of frambœsia, with those of elephantiasis.<sup>a</sup>]

*Treatment.*—The only case which I have seen, occurred in a person who came from Madeira; but it is also found at St. Domingo, and in the Isle of France. It has been cured, I believe, by the exhibition of arsenic. Many cases have been improved by this medicine; and slight cases have been absolutely cured by it; but, for the most part, the treatment is very unsatisfactory.

[The vapour-douche, friction with volatile liniments, or (what is still more efficacious) the repeated application of blisters to the diseased surfaces, may be tried. When the disease is limited in extent (to the ears or face, for example), the ointment of hydriodate of potash (one scruple to an ounce of axunge) is often very beneficial;—the vapour-douche being frequently applied at the same time. When it is more extensive, and the tubercles have not ulcerated, warm water, alkaline, or sulphurous baths are to be employed; and, if the state of the bowels admit of them, arsenical preparations, or the tincture of cantharides, are to be administered, with the precautions stated in the treatment of psoriasis. In the advanced stages, M. Bielt has employed the actual cautery with success. It should be kept in view, however, that from the frequent complication of irritation or inflammation of the gastric mucous membrane with elephantiasis, it is impossible to exhibit remedies of an active or irritating character, more especially preparations of arsenic or cantharides. In such circumstances, a soothing course of internal treatment, comprising measures calculated to allay the intestinal affection, is to be adopted; while we endeavour to ameliorate the condition of the skin, by the external treatment already noticed.<sup>b</sup>]

*Barbadoes-leg.*—There is another disease which is called “elephantiasis;” but it is local, and does not spread throughout the body, or form tubercles. As it commences in a thickening of the parts below the skin, it is mentioned by Rayer as a disease, not of the skin itself, but as one of those diseases which extends from other parts to the skin.

*Symptoms.*—This affection is what is called “Barbadoes-leg;” and is also called “the elephantiasis of the Arabs.” It is a local disease, occurring in the scrotum, and at the lower part of the leg.<sup>c</sup> The skin becomes diseased, but the

<sup>a</sup> “Library of Medicine;” Volume 1; Pages 419 and 420.

<sup>b</sup> “Library of Medicine;” Volume 1; Page 420.

<sup>c</sup> No part of the body, however, is exempt; the face, neck, breast, abdomen, nates, labia, and margin of the anus, have at different times been observed to be its seat.—“Library of Medicine;” Volume 1; Page 429.

cellular membrane beneath it is the chief seat of the affection. It becomes excessively thickened and indurated; and at Barbadoes, it sometimes affects only one leg.

[Although the progress of the disease is slow, there is more or less general disturbance at the beginning; such as fever, frequent vomiting, pain and erythematous redness over the course of the lymphatic vessels, with swelling of the limb or part. This never subsides entirely, and increases with each returning attack of constitutional disturbance; which intermits and returns at irregular intervals. The limb gradually increases to an enormous size; and becomes so hard as to resist the firmest pressure. In a few months, the general symptoms and local pain disappear; but the distended and enormously swollen part—whether the leg or the scrotum—not only remains in that state, but increases. The scrotum has been known to weigh nearly sixty pounds; and one of the lower extremities to attain a weight equivalent to that of the rest of the body. The skin—at first pale, smooth, and shining—becomes rough, hard, thickened, and covered with scaly incrustations of various thickness; it afterwards cracks in all directions, and deep and painful fissures ensue. The lymphatic glands, which were from the first hard and swollen, sometimes inflame and suppurate, and even mortify. Deep abscesses form, and discharge a large quantity of fetid pus; and death occurs with the ordinary symptoms of adynamic fever.

*Treatment.*—In the first stages of the disease, local and general bleeding may be necessary, with rest and the horizontal posture of the limb. At a later period, gentle and frequent friction, compression carefully applied, daily shampooing, and the vapour-douche, may be employed. Frictions with the different preparations of iodine, are of great service; but should inflammation come on, their use must be immediately suspended.<sup>a</sup>]

A friend of mine says it is produced by a kind of flea; which is not satisfied with being on the surface, but forms a bag beneath, in which it lays its eggs; from the continued irritation of which, he says, the disease is produced. How that may be, I do not know. The blacks, in the West Indies, suffer under the affection; and they are very dexterous in dragging out the bag, by means of a needle;—so that no harm ensues. But if any portion be left, an egg usually remains; and the disease proves very troublesome. The name given to the insect is “chigoe.”

### SECTION III.—ICHTHYOSIS.

*Nature.*—The next disease which I shall notice, is classed by Rayer among *organic* diseases of the skin, and is one which we occasionally see. It is termed “ichthyosis.”<sup>b</sup> It is not so rare a disease but that every one, in the course of his life, may perhaps see a few cases. It is classed, by Willan, with scaly diseases;<sup>c</sup> but as the scaly diseases I have mentioned<sup>d</sup> have been classed, with a number of others, in the list of inflammatory affections, this could not come in with them. Moreover, although a scaly disease, it is necessarily separated, in the arrangement of Rayer, from pityriasis, lepra, and psoriasis; because all those scaly diseases are of an inflammatory nature.

*Characters.*—In this disease, there is no inflammation whatever. The skin is neither red, hot, nor tender; but it is covered by a large number of scales. These scales have been supposed to resemble the scales of a fish; but they are not imbricated. Indeed, in many parts, the skin looks more like the feet of fowls, than any thing else. This will give us the best idea of it. At a little distance from a person labouring under the disease, we might suppose that the skin was dirty;—the scales which lie upon it being of a bluish colour. It exists in various degrees

<sup>a</sup> “Library of Medicine;” Volume 1; Pages 429 and 430.

<sup>b</sup> From *ixthya*, the scale of a fish.

<sup>d</sup> Pityriasis (Page 403); Lepra (Page 404); and Psoriasis (Page 406).

of intensity, and of extent. The constitution is not in the least degree disturbed;—the health is not at all affected, There is nothing to be seen, but this organic affection of the skin;—the cuticle being formed with this diseased character.

The affection will sometimes cover the whole body. It is said, in books, that it is not seen exactly over the furrow of the spine; but in the cases which I had in the hospital<sup>a</sup> (or, at least, in one of them), that part was covered with scales, exactly like the rest. The face, in those cases, was very little affected; but the back of the neck suffered pretty severely.

*Causes.*—The cause of this affection is not known; but it sometimes occurs from original constitution. I had two brothers under my care for this complaint; in each of whom it made its appearance without any obvious cause. They were born at Sheerness, and lived at Woolwich.<sup>b</sup> It seemed to be constitutional; and occurred in the progress of their age. It has sometimes been known to be hereditary. The skin feels dry and rough, and there seems to be no perspiration;—in general, the skin ceases to secrete a watery fluid. If the affection be more intense, it exhibits exactly the appearance that Alibert has represented in Plate 37, as occurring on the knee; and which he calls “ichthyose nacrée.”

*Treatment.*—The disease is generally thought, I believe, to be incurable;—at least, that internal medicine has little power over it. Pitch, however, is said to do good. Dr. Willan says he cured a lady, by giving her pitch. The pitch was made into pills; and she took as many as she could swallow in a day;—altogether one or two ounces. I certainly did not give these patients as large a quantity as they could have taken; but each boy swallowed forty to fifty pills, three times a day. One of them put them into his hand, and swallowed them as children do sugar-plumps: he must have taken, every day, a quantity of pitch, nearer two ounces than one. At the same time that I employed this treatment, I had one of the boys rubbed over with olive-oil. He was sent to the warm-bath; and when he came out, he was regularly oiled; and in this way he got well. Of course, I was quite in uncertainty, as to whether it was the *internal* or the *external* medicine that did him good;—whether it was the pitch within, or the oil without; and being told that he had a brother in a similar state, I requested that he also might come and be cured. I gave him pitch only; and in larger quantity than Dr. Willan had done; but he was no better for it. I then left it off, and had him oiled;—not all over, but over one extremity only; and that extremity recovered its natural texture, while the other parts remained as they were. It was singular, that if a part which had been oiled touched, by chance, one that had not;—that is to say, if one leg touched the other, this last immediately improved, though not to the same degree. In this way the boy was perfectly cured. These two brothers went out of the hospital, with their skins as smooth and as soft as any girl's; and, for the time, they were certainly cured; but whether the disease will return, I do not know. The free application of oil, in these cases, answered perfectly. With regard to the latter boy, I made careful experiments with the pitch, the warm-bath, and the oil; and such intervals elapsed between the various modes of treatment, that I was perfectly satisfied it was the oil which effected the cure. The disease was quite of the intensity represented in Alibert's thirty-seventh plate. At one period, I used *linseed*-oil; but that did no good; for it dried directly. The *olive*-oil, however, retained its moisture for some time; and answered completely.

*Varieties.*—The ordinary form of the disease is called, by Willan, “ichthyosis simplex;”<sup>c</sup> but now and then it occurs in much severer form; and then it is called “ichthyosis cornea.”<sup>d</sup> The latter of these species is a rare disease; and is of an hereditary nature. Several instances have occurred, in the children of parents

<sup>a</sup> St. Thomas's.

<sup>d</sup> From “cornu,” a horn. See Willan's “Description and Treatment of Cutaneous Diseases;” Order 2; Genus 4; Species 2.

who had laboured under the disease;—not perhaps appearing at their birth; but occurring, like “*ichthyosis simplex*,” at a certain time afterwards.

*The Porcupine Family.*—There is, in Suffolk, a family in whom it has appeared for several generations;—three or four; and (what is singular) always in the male line. No female has been known to have it. Every part of the body is covered with the disease; except the face, the palms of the hands, the soles of the feet, and the glans penis. I saw one of these men;—the grandson of the person who is described in the “*Philosophical Transactions*.” It was a famous family;—called, from the roughness of the skin, “the *porcupine-family*.” This man told me, that the scales were shed every year; and, when I saw him again, they were in the act of falling off. The scales, in this form of the affection, all stand side by side;—they do not overlap each other; and when the limb is put in a certain position, there is a pretty smooth surface, on which you may make a noise, just as in striking horn; but if the part be stretched, so as to separate the scales a little, the divisions may be seen between them.

There was a man, labouring under this affection, who described himself as the descendant of an American savage;—I suppose he wished to make himself appear very wonderful. He came to London, every now and then, to show himself for what he could get. There is also an instance of the hereditary form of this disease, published in the ninth volume of the “*Medico-Chirurgical Transactions*,”<sup>a</sup> by a gentleman residing in Sussex: it occurred in a female. With regard to treatment, I conceive nothing can be done.

#### SECTION IV.—FRAMBÆSIA.

*Its Nature.*—[Frambæsia<sup>b</sup> is a disease indigenous in Africa; whence it has been conveyed to the West Indies and America; it is rarely, if ever, seen in Britain. It is characterized by the evolution of small, red tuberculous tumours; generally distinct from each other at their summit, but connected by their base; and very similar (in their form, colour, and size,) to a raspberry or mulberry. They appear on surfaces of various extent, and occur on all parts of the surface of the skin; but more frequently on the scalp, the face, the axillæ, in the groins, around the anus, and on the organs of generation.

*Causes.*—Persons of all ages may be attacked; but it is more common in children and young people. It is contagious; and is propagated by the contagion of the matter discharged from the eruption. It sometimes appears spontaneously; filth, misery, unwholesome food, and living in damp dwellings, are its more evident exciting causes. Negroes are more frequently attacked than whites. According to Bateman, frambæsia is propagated solely by the application of the matter discharged from the eruption to wounded surfaces of persons who have not previously passed through the disease. It does not appear to be propagated by effluvia; and, like the febrile eruptions, affects the same individual only once during life. In Africa, it is generally undergone during childhood.

*Symptoms.*—The disease begins by solid elevations of a papular nature; and their eruption is sometimes accompanied by general symptoms. The affected surface is sometimes of limited extent; but, in a case which came under our<sup>c</sup> observation, it occupied the whole of the front and inferior district of the thigh;—the size of the tubercle varying from that of a pea to that of a hazel-nut. The vegetations appeared seated in the substance of the dermis, which was in a state of hypertrophy; and, instead of cuticle, they were covered with dry, adherent, thin scales. In warm climates, the tumours frequently ulcerate, and discharge a fetid ichor; which sometimes forms thick crusts. One of the tuberculations generally acquires much larger dimensions than the others; and afterwards forms a foul and

<sup>a</sup> Page 52.

<sup>c</sup> That of Dr. H. E. Schedel.

<sup>b</sup> From “*framboise*, (French,) a *raspberry*.”

sloughy ulcer, which the negroes call the "mama pian" or "mama yaw." The disease is usually of long duration, and leaves well-marked cicatrices; but is not attended by much pain.

*Diagnosis.*—The only disease for which frambæsia may be mistaken, is some form of syphilitic tuberculous eruption. Affections of the latter description often return; their colour is peculiar and characteristic; and they never form fungoid tubercles united by their bases, covering surfaces of various extent.

*Treatment.*—According to Dr. Winterbottom, the natives in Africa "never attempt to cure this disease until it has reached its height; when the fungi have acquired their full size, and no more pustules appear." ("Account of the Native Africans of Sierra Leone.") It would appear, from the experience of those who have seen the disease in tropical climates, that no remedy yet discovered has any influence over its progress. All, therefore, that is necessary in the first stage, is to enjoin a moderate cooling regimen. When the disease is on the decline,—indicated by the eruptions beginning to dry, and then ceasing to multiply and enlarge, the treatment should consist of a moderately nutritious diet, pure air, proper clothing, and the exhibition of sarsaparilla, bark, and the mineral acids in succession; with mild laxatives, and alterative doses of mercurials, according to circumstances. Dr. Bateman states, that the "*mastu-yaw*" sometimes remains large and troublesome, after the rest of the eruption has altogether disappeared. It requires to be treated with gentle escharotics; and, under these applications, soon assumes a healing appearance. Stronger caustics are requisite for the cure of the "*crab-yaw*;"—tedious excrescences which occur on the soles of the feet. In the case we<sup>a</sup> saw under the care of M. Biett, the actual cautery was employed with the greatest success. The different preparations of iodine, and other stimulant applications, appear to be indicated in this disease.<sup>b</sup>]

## CHAPTER IX.

### DISEASES OF THE APPENDAGES OF THE SKIN.

As to diseases of the *appendages* to the skin (such as diseases of the *nails*,) I must leave them to the surgeon. But there is one disease of the appendages, which is very interesting; and, although we do not see it in this country, we have specimens of its effects;—I mean a disease of the hair.

*Trichoma.*—It appears, that the bulbs of the hair sometimes become inflamed; a quantity of acrid stuff is poured out; the hair becomes very much entangled; and sometimes grows, it is said, to a great length. This disease is called "*trichoma*."<sup>c</sup> Sometimes it is called "*plica*;"<sup>d</sup> and, having been common in Poland, it has received the appellation—"plica *polonica*." From the inflammation that exists, the scalp becomes excessively tender. It is found that the bulbs of the hair are gummy, and filled with a great quantity of liquid; and the least touch of the hair induces very great pain. The fluid which is discharged is gelatinous, and sticks the hair together. Some have considered the disease contagious; but I believe that is not the case.

*Causes.*—The causes of this affection are not known. Some ascribe it to the cessation of the perspiration; but any disease may be ascribed to that. Why it occurs more particularly in Poland, than in any other northern countries, is also inexplicable.

*Treatment.*—As to the treatment, we may recommend the warm-bath, and

<sup>a</sup> Dr. Schedel.

<sup>c</sup> From *ῥιζῆ*, the hair.

<sup>b</sup> "Library of Medicine;" Volume 1; Pages 421 and 422.

<sup>d</sup> From "*plicor*," to be knit together.

numerous remedies of different kinds. If antiphlogistic regimen be indicated (by the strength of the system, and the heat of the part,) we may suppose that it will do good. The treatment, however, is very unsatisfactory.

## CHAPTER X.

### DISEASED SECRETIONS OF THE SKIN.

THE diseases of the skin, as a secreting organ, have either been already mentioned, or will be mentioned hereafter. As to excessive perspiration, that I described when treating of intense secretions generally;<sup>a</sup> and as to dryness of the skin, that is rather a symptom of other diseases. Dryness of the skin occurs particularly in ichthyosis, in diarrhœa, and in fevers. As to diseased secretions of the skin with regard to quality, it is very common (as we shall find in rheumatism) for the skin to secrete an exceedingly sour fluid;—so that the perspiration smells something like sour whey. Occasionally, excessive perspiration of parts of the body (either of the hands or the feet) will occur as an idiopathic disease.

*Offensive Perspiration.*—Many people are troubled with sweating hands; so that whatever they touch they moisten. This state, however, occurs particularly in the feet; and is very liable to be of an exceedingly offensive character. Some persons are tormented with this only at certain periods of the year; but some have always very offensive feet, from the diseased nature of the secretions that take place there. Many servants, I believe, have lost their places on account of this misfortune; they have been discovered to have offensively smelling feet. I had a letter, not long ago, from a medical man residing at a considerable distance from London;—stating that he was in this condition. He was in a state of extreme melancholy, on account of the copious and offensive perspiration, which he experienced in the feet. He had consulted every one within his reach; but had derived no benefit. I advised a number of things that occurred to me, as likely to prove beneficial; but I had a second letter from him;—telling me that they had done no good. I endeavoured to alter the secretion by purging, and by applying astringents to the feet; and I advised a number of other things, which I now forget; but which appeared to me rational. I was not sure, however, that they would do him good; and, so far as I know, they did not; for the second letter which I received, betokened the same agony of mind, as that under which the first was written.

This is all I think it necessary to say, respecting diseases of the skin. I have omitted several; some of which are trifling; while with others we are so conversant, that they do not require any observations; and some of them are not common in this country.

<sup>a</sup> See Page 156.

## BOOK II.

### DISEASES OF THE NERVOUS SYSTEM.

---

#### INTRODUCTION.

[In entering on the consideration of those affections to which the nervous system is liable, we think it will materially aid the reader in his comprehension of the subject, if we subjoin a brief notice of the general physiology and pathology of those organs, which are collectively known as the nervous system. More especially when we consider the important additions that have been made to medical knowledge, on these subjects, within the last few years.

*Subdivisions of the Nervous System.*—All recent anatomists have divided the nervous system into the “cerebro-spinal” and the “sympathetic.” The first of these consists, first, of the cerebrum as a centre; secondly, of *sentient* nerves, which pursue their course to it; and, thirdly, of *voluntary* nerves, which proceed from the brain and spinal marrow, either along the base of the brain, or along the spinal marrow, and then along every external part of the animal frame. The second comprehends the internal ganglionic, or sympathetic system of nerves. To these Dr. Marshall Hall has since added a third;—consisting of the *true* spinal marrow, distinguished from the sentient and voluntary nerve which run along its course, as an *axis* of *excitor* and motor nerves. It is the seat of a peculiar series of physiological phenomena, and of a peculiar class of pathological affections: in the former are included *all* the functions which relate to the immediate acts of *ingestion* and *egestion*; in the latter, all spasmodic diseases. He therefore divides the nervous system into—I. The cerebral; or the *sentient* and *voluntary*. II. The true spinal; or the *excito-motory*. III. The ganglionic; or the *nutrient*, *secretory*, &c.

*Cerebral System.*—The first relates to every part of the nervous system which relates to *sensation* and *volition*;—the nerves of sense—the olfactory, the optic, the auditory, the gustatory, and the nerves of touch; and all the nerves of voluntary motion. Its centre is the cerebrum, including the cerebellum; its sentient nerves run variously from the organs of sense, and from the *external* surfaces, first *without* the cranium or spine, and then *within* the cranium or spine, to that centre; its voluntary nerves pursue a similar but retrograde course, *from* that centre to the muscles of voluntary motion.

*True Spinal System.*—A peculiar set of nerves constitutes, with the true spinal marrow as their *axis*, the second subdivision of the nervous system. As those of the former subdivision were distinguished into “sentient” and “voluntary,” these may be distinguished into the *excitor* and *motory*. The first, or the “excitor” nerves, pursue their course principally from *internal* surfaces, characterized by peculiar excitabilities, to the true “medulla oblongata” and “spinalis;” the second, or the “motor” nerves, pursue a reflex course *from* that medulla to muscles having peculiar actions;—concerned, principally, in *ingestion* and *egestion*. The motions

connected with the former, or "cerebral" subdivision, are sometimes, nay, frequently *spontaneous*; those connected with the "true spinal" are always *excited*.

*Ganglionic System.*—Dr. Hall regards the fifth and posterior spinal nerves as constituting an external ganglionic system, for the nutrition, &c., of the external organs. So that the ganglionic subdivision of the nervous system would be divisible into, first, the *internal* ganglionic system, which includes that usually denominated the "sympathetic," and probably filaments of the pneumogastric; and, secondly, the *external* ganglionic system, which will embrace the fifth and the posterior spinal nerves.

*Pathology of the Cerebral System.*—The cerebral system being the system of the sensations, of judgment, and of volition, it is to it that we must refer all morbid conditions of these mental acts or functions. Every derangement of the senses, every form of delirium or of coma, or of perverted judgment, every *act* of violence, must be referred to the condition (primary or secondary) of the cerebrum or cerebellum. The facts which, in a *practical* point of view, are the most important, are those determined by M. Magendie and M. Flourens;—that it is impossible, by lacerations or other modes of injury of the *cerebrum* or *cerebellum*, to induce either pain or contraction in the muscular system. These organs are not endued with *sensibility*, or with the "vis nervosa" of Haller. They are the seat of a self-acting, automatic, sentient, and motive principle,—the  $\psi\upsilon\chi\eta$ , or "soul;" but they are *themselves* incapable either of sensation, or of the production of motion.

When the cerebrum is irritated, delirium ensues; when compressed, coma is induced; when lacerated, we have paralysis of voluntary motion. If other phenomena are seen in diseases of the encephalon, they arise from the extension of these to the true spinal and ganglionic systems, through *irritation*, or *pressure*, *counter-irritation*, or *counter-pressure*;—points of extreme importance, to be noticed very particularly hereafter. In disorders of sensation, of the faculties of thinking, or of volition, we must attend to the course of the sentient nerves, the condition of the encephalon, and the course of the nerves of volition. We must examine the state of the circulation, and the condition of the general system.

The olfactory, the optic, and the acoustic nerves, are (equally with the cerebrum and cerebellum) incapable of *pain*, or of *exciting movements* in the muscular system, when punctured or lacerated. They are, as has been before stated, the *seat* of the sentient principle—the soul; but they are not endowed with the excito-motory principle. But when the optic nerve is inflamed or irritated, there is impatience of light; when the membranes of the encephalon are inflamed and the cerebrum is irritated, there is delirium. When these several textures are compressed, there is amaurosis, and coma respectively; and when the cerebrum is lacerated, there is paralysis of voluntary motion.

*Effects of Exhaustion.*—But, in treating of the pathology of the cerebral system, a subject of the utmost importance comes to be considered. Not only undue arterial action, and venous congestion, induce morbid states of the cerebral functions; but the state of exhaustion from loss of blood, the anæmious condition in chlorosis, &c., induce *similar* effects; and present to the physician anxious cases, which frequently try his skill in diagnosis. Too great action of the minute arteries, congestion in the viens, an anæmious state of the vascular system of the encephalon, alike induce morbidly exalted and impaired conditions of the mental and cerebral functions;—spectra, delirium, insomnia; amaurosis, stupor, coma; violent voluntary actions, or paralysis of the voluntary motions: these are the symptoms which arise out of these morbid conditions of the cerebral system and functions; and these only. Spasmodic actions depend upon the part of another system being implicated. This subject has been well illustrated by the experiments of Sir Ashley Cooper, on the large arteries and veins in the neck of the dog and rabbit.

The influences of position, of a whirling motion, &c., are also worthy of attention. So also are the effects of anxiety of mind, ardent spirits, sexual excess and vice, &c.;—seen in the suicidal mania, in delirium tremens, and in the half maniacal, half imbecile state of mind so frequently seen in such circumstances.

In order, then, to obtain a clear idea of the pathology of the cerebral system, we must imagine the physiological phenomena assuming a pathological character. Now the force of these phenomena may be augmented, diminished, or annihilated. With regard to the cerebral functions, we have, in the sentient nerves, pain or insensibility; in the cerebrum itself, erroneous perceptions, judgments, and volitions, or delirium; or a total deficiency of these faculties,—coma; and in the motor nerves, either continual voluntary actions, or paralysis.

*Crossed Effect in Disease of the Encephalon.*—It was well known to the ancients, that disease in one hemisphere of the brain induces paralysis in the opposite side of the body. This fact has been confirmed by modern pathologists. It has been fully ascertained, that disease confined to one hemisphere of the cerebrum, or of the cerebellum, and to one side of the mesial plane in the “tuber annulare,” constantly affects the *opposite* side; while disease confined to one of the lateral columns of the “medulla oblongata” and “medulla spinalis,” affects the corresponding side of the muscular system. The encephalon has a *crossed* effect; the “medulla spinalis” a *direct* effect.

*Cause of Convulsions in Disease of the Encephalon.*—It has been ascertained that, in experiments, lesions of the encephalon induce *paralysis only*; while lesions of the “medulla oblongata” and “spinalis” induce *convulsion* or paralysis, according to their severity. Hence it becomes important to determine the cause of convulsive affections, in disease of the encephalon. This cause appears to be either irritation or counter-pressure. The former may act through the medium of the nerves distributed to the membranes (as the “recurrent of the trifacial” of Arnold);—as in epilepsy induced by a spicula of bone. The latter is illustrated by a case, recorded by Dr. Abercrombie, in which the anterior fontanel became prominent, and pressure upon it induced convulsion.

*Attempts to Localize Affections of the Brain.*—Saucerotte, in his prize memoir presented to the Academie Royale de Chirurgie, in 1768, and (more recently) MM. Foville and Pinel-Grandchamp, M. Serres, M. Iacrampe-Loustau, and M. Bouillaud, have attempted to show that, besides this crossed effect of the cerebrum, affections of the thalamus, or its *posterior lobe*, induce paralysis of the lower extremities;—so that, if this opinion were true, there would be a *doubly crossed* effect. This phrase is used as a sort of *mnemonic* for those who may wish to speak of these opinions. M. Lallemand and M. Andral, after an examination of an extensive series of facts, have declared that the statement is without foundation. M. Bouillaud has further attempted to show, that disease, or lesion, of the *anterior lobe* of the cerebrum, leads to a loss of the power of articulation. But this opinion is equally contested by the two authors just quoted. It is also desirable, briefly to notice an attempt to localize affections of the brain of a different kind, but equally disputed by these pathologists. MM. Delaye and Foville have stated, that the gray or cortical substance of the brain is principally affected in mania; MM. Bouchet and Cazauvieilh, while they agree with MM. Delaye and Foville in their view of the pathology of mania, contend that in *epilepsy* it is, on the contrary, the white or *medullary* portion of the brain which is diseased. The “tubercula quadrigemina” alone have a crossed effect, both of convulsion and paralysis. M. Ollivier observes, that hæmorrhage into the “tuber annulare” only paralyzes the movements; M. Cruveilhier, on the contrary, asserts that such an affection destroys the sensations and the movements, but leaves the intellect uninjured. It need scarcely be added, in this place, that in those cases in which hæmorrhage occupies an extensive space, affecting both hemispheres of the brain,—as in meningeal hæmorrhage at the summit or base of the brain, or in extensive hæmorrhage within the brain, extending from one hemisphere to the other, or into both ventricles,—*general* paralysis is observed; the same event takes place in cases where a clot of blood is formed in the mesial line in the “tuber annulare;”—the “nodus encephali,” as it has been called.

*Pathology of the True Spinal System.*—The whole order of spasmodic and convulsive diseases belongs to this, the excito-motory division of the nervous sys-

tem; and they all have their source in one of three parts of it. The morbid stimulus may act upon the incident, the central, or the reflex part of the excito-motory arc or arcs, and produce corresponding effects,—corresponding diseases. To use words familiar to the physiologists of Germany, we have a class of “centripetal,” “central,” and “centrifugal” diseases; we may have centripetal or central epilepsy, and we may have spasmodic and other affections, from an affection of the reflex or motor nerves. In this manner, the class of “spasmodic diseases” is subdivided into three *sub-classes*;—a division of the utmost importance in practice, and illustrated by the following table:—

*Table of the Pathology of the True Spinal System.*

I. Diseases of the incident nerves.

I.	1. Dental	} Irritation in infants.	{	1. The crowing inspiration.
	2. Gastric			2. Strabismus; spasm of the fingers and toes; strangury; tenesmus; &c.
	3. Intestinal			3. Convulsion.
				4. Paralysis.
II.	1. Gastric	} Irritation in adults.	{	1. Hysteria.
	2. Intestinal			2. Asthma.
	3. Uterine			3. Vomiting; hiccup; &c.
				4. Epilepsy.
				5. Puerperal convulsions; &c.

III. Traumatic tetanus; hydrophobia; &c.

II. Diseases of the spinal marrow itself.

I. Inflammation and other diseases.

II. Diseases of the vertebræ and membranes.

III. Counter-pressure, &c., in diseases within the cranium.

IV. Centric epilepsy, tetanus, &c.

V. Convulsions from loss of blood, &c.

III. Diseases of the reflex or motor nerves.

I. Spasm.

II. Paralysis.

1. Spasmodic tic.

2. Torticollis.

3. Contracted limbs, &c.

What are the parts or organs physiologically connected with this system? The orifices, the sphincters, the organs of ingestion, of expulsion, and of exclusion. Now these are precisely the parts and organs involved in diseases of the true spinal system. The *physiology* has become *pathology*. The *larynx* is closed in the convulsions of children, in epilepsy, in puerperal convulsion; it is partially affected in the croup-like convulsion, in hysteria (in which there is frequently loss of voice), &c. The *pharynx* is affected in some of these diseases. The respiratory muscles are so in all. In epilepsy we observe affections of the sphincters, and even of the ejaculators.

*Influence of the Passions.*—The *passions* exert a singular influence over these and *all* the functions of the excito-motory system. Sickness, panting, convulsions, relaxation of the sphincters,—these, and a thousand other affections of this system, are induced through the mysterious influence of disgust, fear, &c. Infantile convulsions and epilepsy are renewed by vexation, &c. Of all diseases, those arising from fright are the most formidable.

*Pathology of the Ganglionic System.*—The “cerebral” system is concerned with *psychical* or mental acts merely; the “true spinal,” with *physical* acts on the masses of bodies to be appropriated to or expelled from the animal economy; while the “ganglionic” system relates to the *chemical* changes in the disposition of the *atoms* of the animal body, its solids, fluids, &c.;—its office being, to regulate the interstitial absorption, deposition, re-absorption, and the secretion of the *atoms* or particles of which the animal frame is composed, and of the ingesta and egesta.

In the case of disease or injury of the fifth (trifacial) nerve within the cranium, besides the loss of sensibility and of its excito-motor property, other phenomena are observed. The nostril loses its susceptibility to the impression of stimuli; and eventually the eye, not being nourished, shrinks and collapses. The power of the masticatory muscles is impaired; but the face is not distorted by any apparent paralysis. These facts, which have been confirmed by cases and experiments, prove that the *fifth*, as a ganglionic nerve, regulates the nutrition of the eye, gums, &c.; and that defective nutrition of those parts is one of the results of injuries inflicted upon it.

The effects of the division of the pneumogastric nerve on the lungs and stomach, as demonstrated by the experiments of Dr. Wilson Philip, and Sir Benjamin Brodie, prove this to be a nerve of secretion. There are probably no cases on record,—with the exception of a very defective one by M. Gendrin,<sup>a</sup>—where the pneumogastric was distinctly affected; and in which the influence of its disorganization upon the lungs, stomach, and other internal organs, was traced. Some diseases are obviously affections of the internal ganglionic nerves; we have *augmented* action, for instance, of the liver and kidney in the cholera europæa, and enuresis;<sup>b</sup> we have *paralysis* of the same organs in the cholera indica, in some cases of icterus, and in ischuria. The effect of injury or disease of the spinal marrow on the quantity and constituents of the urine, is also well established.

The whole nervous system seems to have a certain influence over the action of the heart. According to the experiments of Legallois and Dr. Wilson Philip, to crush the brain or spinal marrow enfeebles or arrests the circulation. The same effect is produced by crushing the limbs or viscera; and this is doubtless effected through the medium of the ganglionic system. In an eel, in which the brain had been carefully removed, and the spinal marrow destroyed, the stomach was violently crushed with a hammer. The heart, which previously beat vigorously sixty times in a minute, stopped suddenly, and remained motionless for many seconds. It then contracted; after a long interval it contracted again, and slowly and gradually recovered an action of considerable frequency and vigour. No experiment can demonstrate, more clearly, the effect of violence inflicted upon the system generally. The experiment is the more remarkable, because the connection and influence of the brain and spinal marrow were entirely removed. The organic structures must have been the medium through which the effect of the violence was conveyed to the heart. Similar events have occurred in surgical practice;—the case of the late Mr. Huskisson for example. The tremendous vehicle passed over his thigh. The action of the heart failed; and the surgeon waited for reaction—for an opportunity for amputation—in vain.<sup>c</sup>

---

## CHAPTER I.

### PHRENITIS.

HAVING concluded my observations on diseases of the surface,<sup>d</sup> I now proceed to consider those affections which are situated in the interior of the head. The first disease of which I will speak, according to the order I have hitherto pursued, is inflammation within the head; which is called “phrenitis.”<sup>e</sup>

<sup>e</sup> From *φρεν*, the mind; and “itis,” inflammation.

## SECTION I.—SYMPTOMS.

*Ordinary Symptoms.*—In the first place, we have the symptoms common to inflammation in every part; only that, in this case, they are situated within the head. There is a sense of constriction of the forehead; which answers to the sense of tension in other situations. Perhaps, also, we have vertigo, and violent pain and throbbing in the head; throbbing of the carotid arteries; throbbing at the temples; throbbing at the back of the neck; and an acute stabbing pain in the head, or a dull heavy pain. Although we cannot examine the part itself which is inflamed, still we have evidence of morbid heat; and that heat extends to the external part which is not inflamed; so that here is another mark of inflammation;—increased heat. Although we cannot see the inflamed part, and therefore cannot discern the redness, yet this frequently extends to the eyes; so that they are very much suffused; and thus we have a third mark of inflammation. Three, then, of the marks of inflammation are to be observed, though not actually at the part itself. Swelling, of course, is out of the question. Besides the pain, there is what we usually notice in inflammation;—morbid sensibility, extreme excitability of the mind, and intolerance of light and noise.

*Delirium.*—Another set of symptoms arises from a disturbance of the *function* of the part;—so that there is delirium; and it is not of a mild or slight character, but violent;—"delirium *ferox*." In the greater number of cases, there is also constant watchfulness; the patient cannot sleep at all.

*Symptoms.*—As to the *secondary* symptoms, which arise from sympathy, we have pyrexia, which is perhaps violent. The pulse is accelerated, generally full, and perhaps also hard. At any rate, in the greater number of cases, it is accelerated; and it is generally full and firm, if not absolutely hard. If it should so happen that, instead of violent delirium, there is more or less stupor, we may then have a *slow* pulse; but in general there is violent delirium, and a *full* pulse. The tongue is of course altered in appearance. It is at first *white*;—the usual colour of the tongue, in active inflammation; but as the powers sink it becomes brown. Not unfrequently, the stomach is affected;—so that, in the greater number of cases, there is vomiting; and as the bowels become exceedingly torpid, there is likewise costiveness. The urine is generally high-coloured. As the disease continues, it is by no means unusual to notice convulsions; and at last, perhaps, paralysis.

*Varieties in degree.*—Inflammation of the brain itself and its membranes, like all other inflammations, may vary in degree. There may be mere headache;—characterized by a sense of tension, heat, and a degree of giddiness; or there may be simple giddiness without any pain, or watchfulness, or sleeplessness; and from these symptoms there may be all the intermediate grades, up to the most intense inflammation, and the most furious delirium.

*Varieties in Duration.*—The same variations may occur, also, with regard to the *duration* of the affection. Sometimes this inflammatory affection of the head, will destroy the patient in a few days, or even in a few hours; and sometimes these symptoms may last for years. Chronic inflammatory headache (which is neither more nor less, in many cases, than phrenitis) may last for many years. When the disease is of this chronic character, we may have merely some thickening of the membranes; but if lymph be effused, they are rendered still thicker. There may be continuous adhesions; and even the bones themselves, as well as the membranes, may become exceedingly dense and thick.

*Diagnosis of Meningitis and Cerebritis.*—These symptoms may arise either from inflammation of the brain itself, or of its membranes; and either of these affections is called "phrenitis." There are no distinctive symptoms in these cases. It is mentioned in books that the pain is more acute, and the pulse harder, when the *membranes* are inflamed (as in the case of "arachnitis;") but that when the *substance* of the brain is inflamed, the pain is more of a dull character, and the pulse is not so hard. But although, now and then, we may make a very good

guess, as to how it may turn out after death; yet, I believe, in the greater number of cases, we shall be wrong. In the majority of instances, both parts are inflamed;—the substance of the brain and the membranes; and frequently, when the membranes only are inflamed, there is not an *acute*, but a *dull* pain; and not *hardness* of the pulse, but merely *rapidity*. Besides, the distinction is of no importance. The membranes are more frequently inflamed than the substance of the brain itself; and when the substance is inflamed, it is very rare indeed for the membranes not to be inflamed likewise. It has been said, that when the *superficial* part of the arachnoid is inflamed, there is usually delirium; but that when the *basilary* part is affected, there is rather stupor and convulsions;—at any rate, spasmodic movements. So that some would have a diagnosis between inflammation of the brain itself, and inflammation of its various membranes; while others go still further, and when the membranes are inflamed, (at least the arachnoid,) they would have us to infer that it is the superior part, if there be delirium; but that it is the basilary, if there be stupor and convulsions. This is the statement of some French writers.

[We find, that in meningitis<sup>a</sup> of the convexity of the hemispheres, the surface of the brain itself is always irritated and generally inflamed; that the consequent disturbances of the functions of the organ are the principal, though *indirect*, signs of the meningitis; and that these disturbances are characterized, as a general rule, by high excitement and irritation;—evinced by smart symptomatic fever, headache of the acute kind, great sensibility of the eye and ear, delirium of the more violent kind, and convulsive movements; which, from the usually great extent of the cerebral inflammation, may affect any or all parts of the muscular system, simultaneously or in succession, without being restricted to a particular limb or part. Now, in general cerebritis, no less than in meningitis, the functions of the brain are disturbed; but the disturbance is characterized less by excitement than by depression. Nor is this difficult to understand; for when the substance of the organ is extensively diseased, the abolition of the function speedily overtakes, as it were, and supersedes any excitement existing in the early stage. Accordingly, though the invasion be attended with fever, quick full pulse, exalted sensibility, &c., (as is apt to be the case when general cerebritis is complicated with meningitis,) yet these symptoms of vascular excitement are less violent than in pure meningitis of the convexity; and they are promptly replaced by a slow irregular pulse, stupor advancing to coma, muscular spasms, and universal paralytic relaxation. In some cases, we have seen universal cerebritis wholly devoid of vascular excitement; and attended, from first to last, with a preternaturally slow, weak, and irregular pulse. In such instances, when post-mortem examination shows the membranes to have been implicated, we suspect that they had been attacked only secondarily; for, in certain instances of the kind, we have noticed slight vascular excitement—evinced by heat of the head, with quickness of speech, manner, and movements of the eye—to supervene in the mid-career of marked symptoms of depression. It is not to be supposed, however, that convulsions—whether in the form of mere twitching, or of violent and general fits—are incompatible with symptoms of depression. We<sup>b</sup> have repeatedly seen them in general cerebritis; and they may result either from the irritation of coexistent meningitis, or from counter-pressure on the “medulla oblongata;”—the superior extremity of the “true spinal or excito-motory column.” Besides convulsions, there may be *tonic* spasms;—that is, rigid contractions of limbs; and it is maintained by Rostan, Lallemand, Bouillaud, and others, that these are peculiar to cerebritis, and foreign to meningitis; but their idea appears to extend to the cerebritis of the surface which accompanies meningitis, and it therefore includes the bulk of the cases which we denominate “meningitis.” However, when the rigid contractions occur in general cerebritis, or in meningeo-cerebritis, it is maintained that they are not restricted

<sup>a</sup> From “meninx, menigis,” a membrane; and “itis,” inflammation.

<sup>b</sup> Dr. James Hope.

to a particular limb, side, or part; but affect a variety of parts on both sides at the same time; also, that when the rigid spasms relax, the limb recovers its muscular power and sensibility.<sup>a</sup>]

## SECTION II.—MILDER FORMS OF THE AFFECTION.

Let us now consider certain milder forms of this affection, together with some other affections; which, though not inflammatory in their nature, present many points of resemblance.

*Inflammatory Headache.*—When phrenitis occurs in a very mild degree, the patient complains, more or less, of headache; but that headache is attended by a throbbing sensation. There is a throbbing pain in the head, or a throbbing of the temples, or of some particular part; and the pain is usually most intense in the forehead. In the greater number of cases, the patient puts his hand up to his forehead. It is rendered worse by heat;—by the heat of the bed, and by the heat of the fire. It is rendered worse, too, by stooping; and especially on rising again after stooping. This will cause a sensation of great weight, or even a cutting sensation, to be experienced within the head. It is generally worse in the morning;—from the continued heat of the bed, and the horizontal posture. There is likewise, in many cases, drowsiness; and yet the patient perhaps cannot sleep, on account of the intensity of the pain. There is a morbid heat of the head, and a morbid sensibility to light and sound. These produce, not an agony, but an uneasiness. The least noise frets the patient; and so does the light. The mind, too, in these cases, is almost always irritable. Patients are easily put out of humour; and they are impatient. In these cases, the pain rarely extends below the zygoma. If it be an inflammatory affection *within* the head, the face does not suffer; nor does the pain extend, for the most part, down the back of the neck. The pain is usually not increased by touching the scalp. Now and then, however, the external part may be affected, as well as the internal; and then there may be tenderness of the scalp; but, for the most part, there is not.

*Rheumatism of the Scalp.*—In rheumatism of the scalp, on the contrary, there is almost always extreme tenderness. Many cases occur, where we are exceedingly anxious to ascertain whether the pain complained of is internal or external; and, by attending to these marks, we shall be able to say whether it is internal, or external. In rheumatism, there is not only, for the most part, tenderness of the scalp; but the pain generally extends beyond the cranium. It frequently runs down the face; it runs behind the ears, and down the neck; and, very frequently, there is rheumatism in other parts. Sometimes there is great sweating;—just as in common rheumatism.

*Rheumatism of the Membranes.*—Now and then, however, the internal parts suffer in rheumatism; so that we may have both external and internal inflammation. In these instances, the nature of the case is in general easily made out, by observing that, although the scalp is tender, and the pain runs down the face, and the back of the neck;—although there is rheumatism in other parts, and the pain is worse in the evening; yet there is likewise giddiness, drowsiness, and a throbbing of the inner part of the head. When we see two sets of symptoms like these, we may be sure that the two parts are affected;—the external and the internal; and, in such a case, although the patient is labouring under rheumatism, yet we must not trust to such ordinary remedies as, for the most part, cause rheumatism to disappear sooner than it otherwise would; but we must treat the case as phrenitis. Very frequently this pain of the head, when it is rheumatic, is attended with a great sense of coldness. In these cases, too, the pain, for the most part, is worse in the afternoon or evening; but the latter is by far the most usual; and that without any cause which we can discover. The pain is not worse in the morning; and the

<sup>a</sup> "Library of Medicine," Volume 2; Pages 38 and 39.

addition of even two or three flannel nightcaps, does not make it worse; but in inflammatory pain of the internal part of the head, these things could not be borne; and (as I have before said) the pain is almost always worse in the morning;—which arises simply from the mechanical circumstance, that the horizontal posture allows the blood to go more easily to the head, and renders its return more difficult; and from the bed increasing the heat of the body. But in rheumatism (which is of a cold nature) this very pain is almost always worse in the evening, and is relieved by heat. These circumstances clearly point out the nature of the case.

*Hemicrania.*—When pain of the head is of another description,—neuralgic,—we may frequently discover its nature, by the absence of these internal symptoms, and by the pain running along particular nerves. Sometimes it runs in the course of the supra and infra-orbital nerves; sometimes it is particularly seated in the branches of the fifth pair near the ears; and sometimes we may trace it along the mastoideus.

At other times, however, it does not run along the course of particular nerves; but is situated in one spot, where there is a violent continual pain; and this is very common in hysteria. Sometimes the part itself is very tender; and sometimes not. When we see the absence of the usual symptoms of inflammation of the head, we may easily, in general, make out the true nature of the case. It very frequently attacks the brain on one side;—not in the situation of the supra-orbital nerve merely, but some other part of the brain; and the pain seems seated there. In this case it is not intermittent, nor does it run along the branches of nerves; but is situated in nerves terminating at one spot on the surface of the body. A pain of this description is sometimes inflammatory; and is attended with these internal symptoms; and then we have to treat it accordingly. It may last for a few days, or for a long time;—coming on at a regular or irregular periods. Such a pain as this is frequently hereditary. I have known many members of the same family suffer from the disease; especially after they have become adults. It is a very hereditary sort of pain;—a pain over the brow; coming on once in three weeks, or once a month, or more or less frequently. It is sometimes produced immediately by mental agitation, by overloading the stomach, or by putting improper articles into it; but, in many persons, in spite of every thing, it will come on (without any apparent cause) every few weeks. In many other cases, there is a local pain;—a pain not intermittent, situated in different parts of the head; and very frequently it is hysterical. It occurs, especially, in hysterical patients.

Thus we have pain of the head of a decidedly *inflammatory* nature; attended with inflammation of the brain itself, or its membranes. We may have pain of the head of a *rheumatic* nature; and the rheumatism may be *active*, attended with heat; or of a *cold* character (which I shall hereafter speak of) relieved by warmth, and worse in the evening; or we may have another headache, which is *neuralgic*; and of that kind called “*tic douloureux*,”—running along particular nerves; but sometimes diffused, with morbid sensibility of a particular part; or of an intermittent character.

*Sick Headache.*—The last kind of headache which I mentioned,\* where it occurs particularly over the brow, has been called “*sick* headache,” because it is attended frequently with sickness. The stomach is deranged in the first instance, or it soon becomes deranged after the headache has begun. More or less, we find headache connected with the affection of the stomach; so that it is called “*sick* headache.” I believe that most persons ascribe this to the stomach; but I am quite sure it is very unjust to lay it to the charge of the stomach, in every case. The stomach has enough to do with diseases of its own, without being accused of the diseases of other parts. I have experienced pain of this description, two or three times, from evident local causes in the head. From having a draught blow on my head, when I have been overheated, I have had intense pain come on. I may mention, that I rarely have any thing the matter with the stomach; but, after this

\* See the last paragraph but one.

pain has existed some time, I have had violent nausea, and then vomiting;—the stomach being affected only *sympathetically*. I have observed, too, in a great number of persons, that this headache has not been preceded by an affection of the stomach. People have declared that they digested well, and that they had a good appetite, not only up to the time of the occurrence of the pain, but as long as the pain was moderate; but when the pain arrived at a certain intensity, then the stomach fell into nausea and vomiting; and was disturbed as much as the head. There is no doubt that persons predisposed to these pains, may bring them on by overloading the stomach, or taking improper articles of diet; but it is to be remembered, that pain of the head will cause disturbance of the stomach; and therefore we have no reason to suppose that the stomach is in fault. I do not think that we ought to infer that the stomach originally is in fault, simply because it is disturbed as well as the head. In a great many cases, the stomach is not affected until the derangement of the head has arrived at a certain point; but the state of the stomach will bring it on; and so also will costiveness; but it is precisely the same with all other affections of the head, and of the alimentary canal. If a person allow himself to become costive, he will be almost sure to have an inflammatory headache; and an inflammatory headache will induce costiveness. It is quite illogical to say, that so many affections of the head arise from the stomach and intestines; and it is just as wrong to say, that all affections of the alimentary canal depend on the head; yet there are parties who, if they do not say so in plain and distinct terms, nevertheless approximate very closely towards it.

*Treatment of Sick Headache.*—This is a most intractable complaint. I have known it affect many persons, in whom all the remedies that were employed, failed in accomplishing any material good. If the system be too plethoric,—if we find the pulse full,—if we find the patient eating and drinking too much, we may do good to a certain extent, by bleeding and lowering the diet. Now and then the pain is so intense, that a degree of phrenitis occurs; and we must then treat it as phrenitis. But where it only comes on from time to time, I do not think we can easily remove it; though we may lessen it, and prevent it from being as bad as it otherwise would. If the patient avoid every thing likely to do harm, and pay proper attention to the bowels, this object may be effected. Now and then, the stomach is very much out of order, and an emetic may mitigate urgent symptoms; but it will not produce material benefit. I have tried iron, sulphate of quina, arsenic, and every medicine that suggested itself to my own mind, or has been recommended by others; but it has been in vain. After a number of years, this description of headache will sometimes cease of its own accord.

### SECTION III.—MORBID APPEARANCES.

*High Vascularity of the Membranes.*—After death we find, with regard to the membranes, either a distinct red net-work, or a uniform redness, of greater or less extent. The minor degree of inflammation, is where we can discover each vessel distinctly; and the higher degree is where there is uniform redness in any portion; because the uniformity of the appearance arises from the excessive number of vessels which contain red blood. These patches vary exceedingly in extent and frequency.

*Inflammation of the Arachnoid.*—It is probable that, of the three membranes of the brain, the arachnoid is most frequently inflamed; and we may have inflammation, not merely in the enveloping portion, but likewise in that which lines the ventricles. Either one portion or the other, or both, may be inflamed. When this membrane becomes inflamed, it is opaque; and it also becomes thickened;—both which are common effects of inflammation.

There is generally a certain quantity of serum, either *upon* or *in* the brain; and in the greater number of cases (as I mentioned<sup>a</sup> when speaking of serous mem-

<sup>a</sup> See Page 103.

branes in general) the serum is turbid. Not only, however, is the serum turbid, but often larger or smaller portions of fibrin are seen in it.

Now and then the inflammation is so intense, that layers of lymph are found either upon the brain externally, or in the ventricles. Sometimes the fibrin is not in the form of layers, but has a jelly-like appearance; and we find this appearance most frequently at the *base* of the brain. Now and then we find absolute adhesions. In general, when there is such violent inflammation, death takes place too soon for the layers of fibrin to become adherent: but death may not take place so rapidly; the process may be slow; the inflammation may not be so acute; and then adhesions may be formed. If the disease be rather chronic, this fibrin may become very thick and organized; and we may have it to a very great extent. I was shown, by a friend of mine, a portion of fibrin which covered nearly the whole of the brain; and I should think, that nearer a third than a fourth of it was an inch in thickness. It was perfectly organized; and formed an envelope to the brain. Pus is sometimes produced; and Dr. Baillie says,<sup>a</sup> that he once saw pus all over the surface of the brain;—secreted, I presume, by the arachnoid.

*Inflammation of the Pia Mater.*—If it be the “pia mater” which is inflamed, this of course becomes red; there is more or less of fluid under it; and the fluid, from being confined under the membrane (like the vitreous humour in the cells of its capsule), gives exactly the appearance of jelly. The jelly-like fibrin secreted by the arachnoid, of course lies *upon* the arachnoid; but the jelly-like matter which arises merely from fluid collected in the “pia mater,” lies *under* the arachnoid;—the “pia mater” being within.

*Inflammation of the Dura Mater.*—When the “dura mater” is inflamed, there is redness of it; and now and then it has been said to suppurate, and even to have fallen into a state of gangrene. Frequently, a very large quantity of blood is observed after this inflammation, between the “dura mater” and the cranium. The great turgescence is not confined to the vessels of the “pia mater.” Indeed, in inflammation of the head, the blood is not confined to the interior, but very frequently extends to the scalp; so that all the vessels of the scalp are exceedingly full; and we find an increased secretion of serous fluid in the scalp itself. When the inflammation of the dura mater is local,—the effect of an injury arising either from a diseased bone, or external violence,—we know that the superjacent scalp becomes so affected, that it is quite œdematous; and this is a point attended to by surgeons;—as indicating, after an accident, great affection at a particular spot within. In general, if the dura mater be inflamed throughout, there is great turgescence of the vessels of the scalp, and a serous effusion into it; but if the inflammation be local, then we may have, exactly over the spot, absolute œdema of the scalp.

*Inflammation of the Substance of the Brain.*—When the substance of the brain itself is inflamed, we may observe (on slicing it) a very large number of red dots, besides those which are always seen; and the latter may be double their usual size. We frequently, too, see a large number of minute vessels, which ought not to contain blood, like so many fine red hairs, in the substance of the brain. Now and then inflammation, when situated within the brain, runs on to abscess. This is most usually the case when the inflammation is not general, but local. Dr. Baillie says that he once saw the brain in a state of gangrene.<sup>b</sup> I have myself seen the “dura mater” in that state, but I never saw the brain so;—at least, if we are to judge of its existence from its being very lacerable, and exceedingly offensive. From inflammation, the brain will become exceedingly soft,—so as to be a mere pap;—something like very thick arrow-root and water. There are various degrees, of course; but still the brain is softened. Now and then, we observe softened brain and pus together. The brain generally looks of a dead-white colour; and of course the pus has more or less of a yellow tinge; but frequently

<sup>a</sup> In his “Morbidity Anatomy,” Chapter 24; Section 8.

<sup>b</sup> See his “Morbidity Anatomy,” Chapter 24; Section 15.

they are seen together. It is very rare for the brain to become ulcerated on the surface; but, now and then, such a condition has been seen.

*Appearances in Chronic Inflammation.*—All these effects that I have mentioned, are frequently observed after *chronic* inflammation of the brain, as well as after an *acute* attack; and after chronic inflammation, there is another effect very frequently seen; namely, induration in that part which has been inflamed. Acute inflammation generally causes, besides the redness, a great turgescence of the vessels, large and numerous red dots, distinct red vessels, a great fulness of the larger ones, perhaps more or less effusion, and perhaps abscess. But besides all this, in chronic inflammation, the brain may become hard. Now and then, *acute* inflammation may produce hardening; but I believe it is more frequently the effect of *chronic* inflammation.

*Infiltrations of Pus, and Abscess.* When the substance of the brain has been inflamed, and pus has been produced, it is sometimes not collected in a large quantity, so as to form an abscess; but is seen infiltrated throughout the brain;—so that it has been found in the substance of the organ, in innumerable points. Where this is the case, the substance of the brain is generally softened; because, in the first place, there must be a great degree of inflammation to produce pus; and when the pus is infiltrated so extensively, of course there cannot be induration. There is a great variety in the degree of this; so that we may have mere drops of pus, in the midst of softened portions, and then still larger drops; till we come to such large ones that they are, in fact, abscesses. When the pus is collected in the form of an abscess, there is a capsule produced, of various degrees of perfection; so that sometimes it has been known to have distinct coats. The contents of such abscesses will sometimes be exceedingly offensive; although, of course, no air could have had access to them. The parts surrounding an abscess in the brain, may be in all states;—either perfectly healthy, or diseased and softened, or altered in colour, &c. The matter of the abscess may, of course, remain there, and be found shut up all around; or it may work its way, and burst into the ventricle; or it may burst into the nose, or into the ear. Abscesses more frequently occur in the hemispheres, than in any other part.

*Changes in Consistency.*—With regard to consistency, it is to be remembered, that the firmness of the healthy brain varies at different parts; so that a degree of softness which would be morbid at one part, would be only natural in another. It varies, likewise, according to the time at which we examine a body;—a fresh brain being firmer than one some days old; for as soon as it is exposed to the air, it becomes very soft. With respect to different parts, I need not say that the “*tubercula quadrigemina*” are exceedingly firm. The consistency, too, varies according to *age*. The brain of old people is firmer than that of young persons. There is greater variety in the degree of change of consistence after inflammation, than in any other disease.

*Softening of the Brain.*—When the brain is softened, the part may retain its natural colour; or it may be yellow, it may be of a rosy hue, it may be gray, or it may be whiter than usual. If the change be not the result of inflammation, the part is generally exceedingly white: but the parts around, which are not yet softened, will be found of a rosy colour. But when the brain is softened,—to say nothing of inflammation,—the colour may be of all the varieties which I have just stated. It may be rosy from inflammation, or it may be perfectly white;—the redness being only in the surrounding parts. When the brain is inflamed, the softened parts may be mixed with pus, or with blood. If there be a vessel of any considerable size very near, the blood is poured forth into the softened part. It is the gray part, some think, which is the most frequently softened; but however this may be, every part of the brain is liable to it. When the membranes have been inflamed, it is the cortical part which is most frequently softened. From being in a bad neighbourhood, the brain under the inflammation suffers, and becomes softened. The softening may occur in one or more spots; and, like the existence of pus, it may be exceedingly partial, or may be very general.

The spinal marrow is also liable to softening;—just in the same way as the brain. This softening occurs whether there is inflammation or not; and is seen at all ages, but more particularly in old men. Generally, around the softened part, there is congestion and inflammation. Very often we see inflammation; but frequently we do not. The part is frequently softened, when no inflammation can be discovered. I recollect, distinctly, opening the brain of a young man, whose brain was softened in a great many parts. He was not a patient of mine; but a medical man invited me to see him. He had had paralysis, and the brain was softened; but the part was so white, that we could not conceive there had been the least inflammation. I opened another individual, shortly afterwards, where there were the most intense marks of inflammation;—the brain was absolutely red around the softened part. This is a proof that, though these appearances are often connected with inflammation, yet they are sometimes wholly independent of it.

*Induration of the Brain.*—Induration of the brain may, like softening, be *very* local, or only *rather* local, or it may be *general*; and of course it varies very much in degree. Sometimes it amounts to no more than it would, if it had been hardened by acid; or it may amount to the consistency of wax; and now and then the hardness is still greater;—assuming a fibro-cartilaginous character. When the brain is pretty generally indurated, it is said to be the effect of an acute inflammation; but, as I before observed,<sup>a</sup> acute inflammation more frequently produces *softening* than *hardening*. However, in this case, hardening is more frequently thought to be the result of *acute* than of *chronic* inflammation; but it is only the *first degree* of hardness (namely, that which is equal to the consistency induced by acids) that occurs from this process. When the hardening is *general*, we should not suppose that such extreme induration, as to be called fibro-cartilaginous, could exist universally throughout the brain; nor, indeed, is it the case. The second degree of hardness (*waxy* hardness) is usually *local*; and the same is the case with the *fibro-cartilaginous* hardness. This is exactly what we should *à priori* suppose. These two extreme hardnesses are almost always the effect of chronic inflammation;—perhaps *always*; but I cannot positively say so. It is said that, after fever and general debility, the brain is frequently found in an indurated state; but I do not know this from my own experience.

*Red Dots.*—Then, as to the red dots, they ought to be very numerous, or very large, or indeed both, for us to say that there is morbid redness. We find people differ, every day, about the inflammatory appearances of the substance of the brain;—some contending that there are not more red dots than there should be, and others that there are. I think, therefore, we ought not to be satisfied, unless there are a very considerable number, or they are of very considerable size. They are more usually found in the *medullary*, than in the *cortical* portion of the brain.

*Summary of the Morbid Appearances.*—[The different morbid appearances of which a description has been given, may be summed up as follows:—1. Increased vascularity; redness, either dotted or uniform; no change of consistence or colour; no exudation of fluid, or rupture of vessels. (*Congestion.*) 2. Great increase of vascularity; intense dotted redness; spots of ecchymosis, with a striated appearance, and effusion of drops of blood; increased firmness. (*First Stage of Inflammation.*) 3. Infiltration of blood, and softening of the cerebral pulp towards the centre of the inflamed portion. (*Red softening.*) Infiltration of pus mixed up with the disorganized pulp. (*Yellow softening.*) The *red* and *yellow* softening combined. 4. Serous infiltration of the cerebral pulp; softening of a milk-white colour, without vascularity. (*White softening.*) 5. Increased formation of pus, of various colours; the wall of the cavity lined with a membrane. (*Undefined abscess; encysted abscess.*) 6. Loss of substance on the surface of the brain, or that of the ventricles. (*Ulceration.*) 7. Infiltration of the pulp or its vessels, with permanently concrete fluids; conversion into a more or less dense mass. (*Induration.*)<sup>b</sup>]

<sup>a</sup> See Page 488.

<sup>b</sup> "Cyclopædia of Practical Medicine;" Volume 1; Page 304.

*Precautions necessary in Examining the Brain.*—In examining the brain and its membranes, with the view of ascertaining the existence of inflammation, we must carefully remember, that position has a very great effect; that if the head lie in the usual recumbent posture, and the body be not opened till several days have elapsed after death, extreme congestion may take place at the posterior lobes of the brain;—such as might lead us to suppose, that there had been a vast accumulation of blood during life. If the body have become putrid, this congestion may amount to effusion:—at least, the slightest touch will cause blood to be poured forth. We should carefully note whether position can have caused that accumulation of blood, which we observe on opening the head. We ought also to look at the brain the moment we cut it; because, after it has been cut and exposed to the air, it becomes rather redder than before. Our judgment should be formed, therefore, immediately on slicing the organ. It is likewise to be borne in mind, that both the brain and the spinal marrow, without any accumulation at either part, have a redder appearance when death has taken place *rapidly*, than when it has occurred *slowly*. It is said, too, that they are redder in persons who have died from asphyxia, than in other persons. We must also remember, that the redness constantly varies in different parts;—that there is, for instance, more redness in the “*corpora striata*,” than in many other parts. At the base of the “*thalami nervorum opticorum*,” there are naturally a number of red vessels; the appearance of which we must not mistake for turgescence. We must remember, with respect to colour, that the white part of the brain contains more vessels in early life, than in old age; when it assumes a yellow hue, and has by no means the same number of vessels. We must also remember, that the *gray* portion of the brain is much more “*vascular*” (as it is termed) than the *white* portion. When a part is redder than usual, there are not more *vessels* than natural;—the vessels merely contain more *blood* than they ought to do; and therefore the expression “*more vascular*” is, strictly speaking, incorrect: but we merely mean, by that phrase, that vessels contain red blood which ought not to do so; and that those which should, have an increased quantity in them. The gray part is generally more vascular than the medullary portion. All these things are necessary to be remembered, in forming an accurate judgment of the morbid appearances in the head.

*Anæmia of the Brain.*—In many states of the body, the very reverse of all these appearances takes place. In some diseases the brain will become bloodless. In cases of starvation, it is said, the brain will become colourless. This may be expected. When persons die through the want of some natural stimulus to which they have been accustomed, there is also this extreme whiteness of the brain. I have seen this condition, quite independently of a general cause; quite independently of the loss of blood, or the want of food, or the want of stimuli; but from local disease of the cerebral arteries. I have seen the arteries diseased;—so that they would not admit of a proper quantity of blood passing through them; and the brain has consequently been rendered far whiter than it naturally is. However, this whiteness is said sometimes to occur, after there have been signs of irritation of the brain: but I should think that it more frequently arises from the want of blood throughout the body, or from causes which prevent the brain from receiving its proper quantity of blood. So much, therefore, for the morbid appearances.<sup>a</sup>

*Comparative Frequency of the Several Forms of Cerebral Inflammation.*—[Inflammation of the “*dura mater*,” exclusive of that produced by fractures and other surgical affections, is perhaps the most rare variety. The “*phrenitis*” of old authors,—that is, inflammation of the membranes and surface of the convexity of the brain, with furious delirium and rapid sinking,—is not, according to our<sup>b</sup> observation, a frequent affection in this country; but it is much more common in

<sup>a</sup> One of the most splendid books on the morbid appearances of the brain, is Dr. Hooper's. Some of the plates are rather too showy; but still they exhibit, extremely well, the appearances of inflammation. Representations of this affection, are also given in Dr. Baillie's work on Morbid Anatomy; but the plates, not being coloured, do not show it very clearly.

<sup>b</sup> Dr. James Hope's.

tropical climates, where inflammations in general are characterized by intensity and rapidity of progress. Inflammation of the central parts of the brain, with or without effusion into the ventricles, and not unfrequently conjoined with meningitis at the base or on the hemispheres,—occurring principally in children, and running a protracted course of fifteen to thirty days, with two or three well-marked stages,—is an affection which, under the designation of “hydrocephalus,” is perhaps not surpassed in frequency by any other single variety of cerebral inflammation. General acute cerebritis is rare; partial is pretty common, especially with more or less meningitis; chronic partial cerebritis is perhaps equally, or even more common.<sup>a</sup>]

#### SECTION IV.—CAUSES.

Inflammation of the brain is less frequently an *idiopathic*, than a *symptomatic* affection. It is more frequently seen as an accompaniment of *fever*, than of any other disease.

*Heat and Cold.*—It will arise, like any other inflammation, from cold applied to the body, especially when the latter is over-heated. It will occur also from simple heat; for if a person in a hot climate be exposed to the direct rays of the sun, without any covering on his head, (especially if he be lying down,) inflammation of the brain may be the consequence. This is called “insolation.” Sometimes, instead of inflammation, apoplexy is induced; but this more frequently occurs when the patient is making a violent exertion at the same time.

*Intoxication.*—Intoxication will produce inflammation of the brain. Spirituous or vinous liquors irritate the brain, or they would not intoxicate; and the irritation may amount to such a degree, that inflammation may occur. The same circumstance arises from mental irritation.

*Mental Irritation.*—Mental irritation, whether it arises from rage or anxiety, causes a great excitement of the brain. Want of sleep, or long-continued watchfulness, will have the same effect. Long-continued excitement, of a less degree, may amount to the same thing as violent excitement for a short time. Excessive use of the brain cannot take place, without the want of sleep and anxiety. No person studies, without being anxious to *learn* what he studies; and his love of study induces him to sacrifice sleep.

*Narcotics.*—Narcotics, which stimulate the brain, may also induce this condition of that organ. It is very common, after large doses of opium, hyoscyamus, or stramonium, to find a throbbing in the vessels of the head. After a person has taken prussic acid, he may experience throbbing in the head, or throbbing of the throat, and more or less delirium.

*Mechanical Injuries of the Head.*—Wounds, of all descriptions, are common causes of inflammation within the head. Contusions, concussions, penetrating wounds, and mechanical injury of the head, may act in two ways:—as *exciting* and as *predisposing* causes. We may have inflammation directly induced by them; or such morbid irritability excited, that any common cause, afterwards applied, may easily produce inflammation;—so that when a person has had injury inflicted on the head, (whether it be fracture or any thing else,) it is sometimes very dangerous for him to drink either wine or beer, or spirituous liquors, for a very great length of time; or perhaps even to eat meat; for the slightest cause, in these circumstances, may give rise to inflammation. This disposition will occasionally last for years. I recollect seeing a person who, twenty years before, had suffered fracture of the skull; and, on taking a glass of spirits, he immediately became almost delirious. I mentioned, when speaking of inflammation in general, that I had seen delirium induced from rheumatism of the scalp, after an injury to the head.<sup>b</sup>

*Cessation of an Eruption.*—Phrenitis has sometimes arisen from the cessation

<sup>a</sup> “Library of Medicine;” Volume 2; Page 46.

<sup>b</sup> See Page 112.

of an eruption. It is said that cessation of itch, has been followed by inflammation within the head.

*Removal of a Tumour.*—Sometimes it has arisen from the removal of a tumour. The tumour has taken off a great deal of excitement. It has required a considerable quantity of blood to nourish it; and, the tumour being removed, there has been so much more energy throughout the system, and the brain has consequently suffered. This has more frequently occurred, when the tumour has been situated on the head itself. This is exactly what we should suppose.

*Amenorrhœa and Costiveness.*—Analogous to the cessation of an eruption, are amenorrhœa, and costiveness. Women, every day,—from the cessation of the menses, when they ought to menstruate,—become the subjects of violent headache, giddiness, and symptoms of that description. Now and then actual inflammation of the brain will take place. Costiveness frequently induces headache. If a person pass his usual time for having a motion, headache takes place; and it is said that inflammation of the brain has sometimes been the consequence of mere costiveness.

*Inflammation of the Eye, Ear, or Nose.*—Inflammation of the eye, or the ear, or the nose, or the frontal sinuses, will sometimes spread to the brain. Phrenitis has frequently carried off patients who have had nothing more, at first, than inflammation of the parts I have just enumerated. Of course, inflammation will spread in the head, just as in other parts of the body. When the nose and the sinuses have been inflamed, in a great number of cases the bones have been found carious. I have several times seen phrenitis arise from disease of the ear. When a person has what is called “otorrhœa,”<sup>a</sup> or “otalgia,”<sup>b</sup> (in common language, a discharge from the ear, or ear-ache,) we ought to be on our guard to notice the first symptoms he may mention of pain in the head, or the first anxious look that is displayed. The very slightest symptoms of cerebral affection, when there is a cessation of discharge from the ear, ought to put us on our guard. I have seen several cases of this description, where persons have had phrenitis after pain of the ear, or a discharge from that organ. Some have had deafness; some have previously had a pain; and then only discharge. In the first case that I saw, there was a wildness in the person’s look, and a quick pulse; and I expressed to the friends my belief, that the person would never go out of the hospital again alive. This circumstance is mentioned by several authors; and several instances are quoted by Dr. Cheyne, in his work on Hydrocephalus Acutus.<sup>c</sup> In these cases the bone is generally more or less carious. That portion of the “dura mater” which lines the petrous portion of the temporal bone, is found inflamed, perhaps softened; and perhaps there is pus there.

I mentioned<sup>d</sup> that I had once seen the “dura mater” gangrenous; and that was in a case of this description. The portion of the brain lying over the ear was likewise altered in colour;—and even underneath there was a very considerable change. In a short time the patient became violently delirious; no bleeding, no mercury could stop it; and for this simple reason;—there was local disease keeping up the inflammation. There was diseased bone, and old ulceration within the ear; and we might as well have thought of curing inflammation while a portion of depressed bone rested on the brain, or curing an ulcer where there was a piece of carious bone to come away, as curing this disease.

*Venereal Nodes.*—When the skull has become affected by venereal nodes, it is not uncommon for the “dura mater” to become inflamed; and the patient to die, with all the symptoms of phrenitis.

*Erysipelas of the Head.*—When the external parts of the head, the scalp, or the face, are inflamed, it is very common for phrenitis to occur. When erysipelas of the face and head proves fatal, I believe, in the greater number of instances, it

<sup>a</sup> From *ouc*, the ear; and *ρρω*, to flow.

<sup>b</sup> From *ouc*, the ear; and *αλγος*, pain.

<sup>c</sup> “Essays on Hydrocephalus Acutus; by John Cheyne, M. D.”

<sup>d</sup> See Page 487.

does so by inducing inflammation of the brain itself, or of its membranes;—at least, in every case of erysipelas of the head which I have opened, I have found very considerable effusion, either upon, or within the brain, or both. This is not an instance of metastasis, or the occurrence of inflammation in one part from its cessation in another; but appears to be an instance of *extension* of inflammation; for the inflammation of the face, and of the rest of the head, goes on just as vigorously (in the greater number of cases) when phrenitis has taken place, as it did before it commenced.

*Metastasis.*—Inflammation of the brain, however, certainly does occur sometimes, in the way of metastasis. When rheumatism ceases in the joints, or gout ceases in some situations, phrenitis occasionally occurs; and it sometimes takes place after the cessation of inflammation in the salivary glands;—in the case of mumps, or (as it is sometimes called) “cynanche” parotidea.” Phrenitis sometimes occurs immediately on the cessation of this species of inflammation; but sometimes it occurs on the cessation of inflammation of the testicle; which itself occurs, in the first instance, after the cessation of inflammation in the salivary glands. Sometimes the testes are inflamed intermediately. It is very common, after inflammation of the salivary glands, for the testes to become inflamed; and when that inflammation ceases, phrenitis sometimes occurs; but sometimes inflammation of the brain occurs immediately on the cessation of the mumps themselves.

*Its Occurrence in Fever.*—Phrenitis, however, as I before stated,<sup>b</sup> is by far the most frequently seen as an occurrence in fever; and some may choose in this case to consider it *idiopathic*;—excited by the contagion of typhus fever, or malaria, or remittent fever, or by excess, or vicissitudes of temperature. Some contend that fever itself, in many instances, consists of inflammation of the brain; and if they be correct, such phrenitis must be considered idiopathic. If, however, fever be a general affection of the system, then the phrenitis would be considered by those who hold that opinion as *symptomatic*. But these are mere differences of words.

*Predisposing Causes.*—Inflammation of the brain is predisposed to, by native congenital irritability of that organ. Some persons have extreme irritability of the brain. If such individuals be thrown into a passion, or be suddenly and violently excited, they are very liable to phrenitis. Habits of intoxication, injuries of the head, all organic diseases of the head, and especially tumours in or upon the brain, necessarily have the same effect. All these things give a tendency to inflammation of the brain; so that an exciting cause easily becomes efficient.

## SECTION V.—DIAGNOSIS.

[We now proceed to point out the diagnosis between the several varieties of inflammation of the brain, and the diseases with which they may respectively be confounded. These diseases are—*mania: continued fever; delirium tremens; apoplexy; active determination and congestion* of the brain, in various diseases of infancy; *exhaustion*; and *hysterical, neuralgic, rheumatic, bilious, and dyspeptic headaches*.

*Mania.*—Meningitis of the convexity of the hemispheres, with fierce delirium, (“phrenitis,”) is distinguished from mania by the want of the characteristic symptoms which distinguish the latter;—the more or less complete absence of fever and disturbance of the digestive organs, together with its prolonged course.

*Continued Fever.*—The diagnosis of meningitis, both superficial and central, from continued fever with cerebral disturbances (“typhus mitior,” “fièvre nerveuse, ou ataxique essentielle,”) is certainly very obscure. The symptoms of cerebral excitement commence as early in the fever as in meningitis, but more commonly they are later; not appearing till after the lapse of two or three days, or more. The nature of the symptoms may, at the onset, be much the same in

<sup>a</sup> From *κυνων*, a dog; and *αγχιον*, to strangle.

<sup>b</sup> See Page 491.

both; but the progress of the two affections soon renders manifest a remarkable difference between them. The typhus fever is characterized by restlessness in a high degree, by anxiety, low delirium, and spasm, in the form of subsultus tendinum, but seldom more; and these symptoms often alternate with intervals of calmness, and even of sleep, especially in the morning. In meningitis, on the contrary, there is comparatively little restlessness, except in the phrenitic variety; when there is wild delirium, but not the peculiar restlessness of fever. The muscular symptoms are distinct convulsions, spasmodic rigidity, or paralysis; they occur in connection with a state either of delirium, decided somnolency, or complete coma; and these symptoms are more or less permanent;—seldom exhibiting intermissions, except occasionally in the earliest stage. The pulse in fever does not fall below its natural standard, display singular fluctuations in frequency, and finally rise to an extreme degree of acceleration before the fatal event;—circumstances which are highly characteristic of meningitis; nor is the respiration suspirious and irregular in fever, as in meningitis.

Finally: in the later stages of fever there are—a parched, brown, crusted tongue, with sordes on the teeth; dark, offensive fecal evacuations; tympanitic abdomen; sometimes petechiæ; low muttering delirium; the supine posture; slipping down in bed;—symptoms which, taken in connection with the absence of the pathognomonic symptoms of meningitis, render the diagnosis so distinct, that the two diseases can scarcely be confounded.

We<sup>a</sup> have seen cases of general cerebritis present symptoms at the onset very like those of low fever; but these may be detected with little difficulty, by observing that the headache is more intense and permanent than corresponds with the degree of fever, and that it usually increases in intensity as the pulse falls;—a most suspicious circumstance; especially if the pulse also fluctuate, and the respiration be suspirious and irregular. Such are the most prominent diagnostic criteria between inflammation of the brain and fever.

*Delirium Tremens.*—Delirium tremens is distinguished by the absence of the headache; by the peculiar tremors; by the singular hallucinations and spectral illusions, inspiring fear in the patient; by the remarkable wakefulness; by the tractability and inoffensiveness of the delirium; by the copious clammy perspirations; and by the history being that of habitual inebriation: on the contrary, there is absence of the somnolency, coma, convulsive and paralytic affections, and slowness of the pulse, which characterize inflammation of the brain.

*Apoplexy.*—Apoplexy is distinguished by its invasion being abrupt, the paralysis sudden and complete, and the course of the disease short and rapid; whereas, in partial cerebritis, there are most frequently premonitory symptoms; tonic or clonic spasm generally precede the paralysis, which supervenes more gradually; and the course of the disease is irregular, and comparatively slow. It must not be forgotten, however, that when cerebritis is excited by an apoplectic extravasation, spasmodic symptoms, with delirium and fever, may follow the apoplectic phenomena.

*In Infancy.*—In infants under a year old, the diagnosis requires the most scrutinizing attention. “The head hanging over the nurse’s shoulders, and the half-closed eyelids,” says Cheyne, “are alarming symptoms; and in no other complaint do we observe the same knitting of the eyebrows unaccompanied with crying.” There is a quiet, vacant, abstracted air in the face, from non-convergence of the pupils; very different from the lively, violent, and varying expression, indicative of acute pain from other causes than cerebral disease. There are no paroxysms of temper, with alternate extension and retraction of the legs,—as in colic and gripes. If, in addition to these symptoms, there be unusual wakefulness, or unsound sleep with starting and crying, or obstinate screaming without obvious cause; if, while awake, the infant seem drowsy, moan, roll its head restlessly on the pillow or the nurse’s arm, or keep thrusting it backwards against the pillow; if there be a shrinking and frowning aversion to light, a contracted or dilated state of the pupil,

<sup>a</sup> Dr. James Hope.

or disobedience of it to light, and obstinately frequent vomiting not explicable by other causes,—we may feel almost certain, in the absence of great and rapid exhausting causes capable of producing some of the same symptoms (the hydrocephaloid disease,) that we are dealing with the first stage of inflammation. If coma, dilated pupil, blindness, and strabismus, with or even without convulsions or spasms, have taken place, the nature of the case can scarcely be doubted, and the disease has made considerable advances.

The same diagnostic symptoms are applicable to children above the age of one year; and they are rendered more distinct by the declarations or more intelligible manifestations of the patient with respect to pain, fever, and other circumstances.

*When Masked by Previous Exhaustion.*—The most perplexing cases are those in which the cerebral symptoms are unusually masked by great previous exhaustion and emaciation, from tubercular disease, dentition, and chronic gastro-enteritis (“infantile remittent fever;” tabes mesenterica;” “marasmus.”) After scarlatina, likewise, the utmost attention is requisite for two or three weeks, to detect the very first symptom of inflammation of the brain; which, as already stated, generally supervenes in connection with inflammatory anasæra. The occurrence of severe headache should be regarded with the utmost suspicion;—as usually being the earliest sign. If neglected, convulsions, coma, and other formidable symptoms rapidly follow.

*Worms.*—Worms are distinguished by the transitory nature of the headache, vertigo, dilatation of the pupils, convulsions and vomiting, which they occasionally excite; by the absence of fever, of the slow, fluctuating pulse, of the unequal suspicious respiration; and by the symptoms not presenting the progressive increase and regular course usually observed in inflammation of the brain.

*Exhaustion.*—Exhaustion, producing some cerebral phenomena resembling those of hydrocephalus (whence it has been called “the hydrocephaloid disease,”) is distinguished by coldness and paleness of the surface, in connection with a very quick and feeble pulse, and by the occurrence of these symptoms after the operation of exhausting causes.

The diagnosis of nervous, hysterical, neuralgic, rheumatic, and bilious and dyspeptic headache, is so simple, as merely to require in the student a competent knowledge of these several affections.\*]

*Variety in the Paralytic Symptoms dependent upon the Part Affected.*—[Before concluding the subject of diagnosis, we<sup>b</sup> shall briefly allude to the interesting inquiries of some French pathologists; who have endeavoured to point out the parts of the brain affected in cerebrius, by the various modifications of the paralytic symptoms. Paralysis may affect one extremity or both;—one entire side of the body; or the eyes, face, and tongue, either singly, or in a variety of combinations; and there are the same diversities in the state of the sensibility and intellectual faculties. How are these modifications to be accounted for? Several of the older writers had conjectured that, if the nervous filaments could be traced up to their remote origin in the brain, it would be found that each part of the body regularly receives its nerves from a determined part of the brain;—so that any lesion of that part must necessarily affect the functions of the organ to which it sends its nerves. The following are the results of numerous pathological observations made on this subject, by MM. Foville, Serres, Pinel Grandchamp, and Bouillaud. They are, of course, to be received with a good deal of reserve; but we<sup>b</sup> still think them deserving of notice, if it were only to direct others in the path of inquiry.

1. The paralysis of the organs of speech, depends on diseases of one or both anterior lobes of the brain. There are seventeen cases reported in the works of Lallemand, Rostan, and Bouillaud, with paralysis of the tongue; in which the anterior lobes of the brain were found affected with various degrees of inflammation and softening. On the other hand, an examination of about fifty cases, in the

\* “Library of Medicine;” Volume 2; Pages 52, 53, and 54.

<sup>b</sup> Dr. Adair Crawford.

same authors, without loss of speech or paralysis of the tongue, does not afford a single instance of inflammation or softening in the anterior lobes. It should be noted, that there may be loss of speech without paralysis of the tongue,—from mere loss of memory; and M. Bouilland's observations led him to think, that the anterior lobes of the brain preside over the memory of words, as well as over the organs of speech. The above statement, if the facts on which it is founded can be relied on, is certainly very remarkable; and is deserving of further investigation.

We remember an interesting case under the care of Dr. Cuming, of Armagh; in which there was disease in the anterior part of the brain, from a blow received on the forehead, just above the nose. It was found necessary to remove a portion of bone with the trephine; and after a variety of remarkable and untoward symptoms, the gentleman perfectly recovered. One of the prominent symptoms was a loss of the memory of language.

2. The paralysis of the *inferior* extremities depends on disease of the *middle* lobes of the brain, and of the "corpora striata." This conclusion is not supported by the same number of facts as the former.

3. The paralysis of the *upper* extremities depends on disease of the *posterior* lobes of the brain, and of the optic thalami. This is likewise stated as yet resting only on a small number of facts. The paralysis of one arm only, has been observed (in a good many cases) in connection with inflammation at the junction of the posterior and middle lobes. When several parts are paralyzed at the same time, the morbid alterations of the brain are supposed to be more extensive, or seated near the "medulla oblongata." Paralysis of the arm and leg on the same side, or hemiplegia, is supposed to follow the combined affection of the "corpus striatum" and "thalamus;" or else disease of the "crus cerebri," from which these two bodies derive their origin.

The last speculation on this subject which we<sup>a</sup> shall refer to, is one relating to the respective uses of the cortical and medullary substances of the brain. We<sup>a</sup> have seen that the cortical substance has been found, in a great many lunatics, highly injected, and often inflamed; while the medullary substance remained healthy. M. Foville and Pinel Grandchamp have conjectured, from this and some other circumstance, that the *cortical* substance was the seat of *intelligence*, while the *medullary* was intended to preside over *motion*. The principal other grounds of this hypothesis are,—the apparent disease of the cortical substance;—which has been found reduced to a very thin layer, in cases of imbecility; and the small size of the convolutions, and small quantity of cortical substance, observed in the brains of idiots, compared with those of intelligent beings.

In the article "Encéphale," of the volume of the "Dictionnaire de Médecine et de Chirurgie Pratique," just published, M. Foville—whose recent discoveries, on some points of the minute anatomy of the brain, have deservedly attracted much attention—enters at considerable length into the examination of the preceding considerations. He has adduced a number of striking facts and arguments in their support; and lays down the following general propositions:—

1. The joint lesion of the "corpus striatum" and "thalamus" of one side, gives rise to the same paralytic symptoms as the lesion of the whole fibrous substance of the corresponding hemisphere; of which they are, in some manner, the centres or nuclei.

2. The lesion of the "crus cerebri" is followed by the same paralytic symptoms, as that of the "corpus striatum" and "thalamus;" which are themselves, in a great measure, formed by the expansion of the fibres of the crus.

3. A lesion of the "medulla oblongata" produces all the symptoms which arise from the joint affection of the "crura cerebri" and "cerebelli;" and (if we ascend still higher in the brain) from that, also, of the "corpora striata," "thalami," and hemispheres.

4. If we direct our attention to the portion of the nervous system below this

<sup>a</sup> Dr. Adair Crawford.

great centre of the nervous action of the brain, we shall find the cerebral influence unimpaired, in all parts *superior* to any lesion of the spinal marrow; while it is completely intercepted in parts *inferior* to that lesion.

## SECTION VI.—PROGNOSIS.

Cerebritis is a disease always attended with considerable danger. When once fully developed, it had hitherto been generally considered as incurable; but since we have been enabled, by a better knowledge of its true nature, to apply with promptitude more appropriate remedies, the treatment is often successful, even under the most unpromising circumstances. The extremely delicate structure of the brain, however, its situation in a bony unyielding case,—without room for expansion, or any opening for the exit of effused fluids,—and the great importance of the integrity of its functions to the preservation of life, are circumstances which must always connect a considerable degree of danger with its inflammatory affections.<sup>a</sup>

*Prognosis of the different Varieties.*—[Meningitis of the convexity of the hemisphere, though extremely rapid and dangerous if neglected, is perhaps the most tractable form if promptly and vigorously treated. Internal arachno-cerebritis (“hydrocephalus”) is less tractable and more fatal. Before it was known to be an inflammatory disease, the sufferers died, almost without exception; subsequently, the mortality has amounted to about two-thirds; but, in consequence of improvements in diagnosis and the use of mercury, the proportion is now undergoing a considerable diminution. Cerebritis is the most dangerous form of cerebral inflammation; in consequence of the facility with which the organ passes into softening and disorganization. When chronic, and attended with progressively increasing palsy, complete recovery is exceedingly rare. Success in the treatment of chronic cerebritis, however, is daily on the increase;—in consequence of its inflammatory nature being better understood. Formerly,—under the supposition that the symptoms were nervous, neuralgic, rheumatic, dyspeptic, or from debility,—they were treated with tonics, stimulants, and full diet. The general prognosis is more unfavourable, when inflammation of the brain appears during, or shortly after, other serious diseases; especially typhoid fever, the febrile exanthemata, pneumonia, apoplexy, epilepsy, and mania; because, in these maladies, the vital powers are already more or less exhausted, and in some the blood is diseased;—whence active treatment is less easily borne. The same remarks apply to weakly, scrofulous constitutions; especially where several of the family have been affected by hydrocephalus.

*Favourable Symptoms.*—The particular prognosis, in individual cases, is regulated by the symptoms. The following are favourable:—return of natural sleep in contradistinction to somnolent stupor; return of the several secretions;—namely, moisture of the tongue, with cleaning of its points and edges, and removal of dry sordes from the gums and lips; gentle perspiration, or at least softness and coolness of the skin; a free secretion of natural urine, and an open manageable state of the bowels; a simultaneous diminution of the heat of the head; a more equal and regular state of the pulse and respiration; and a corresponding amelioration of the other bad symptoms. The earlier this improvement takes place, the more favourable the prognosis; because, in the first stage, or the early part of the second, the disease may not have proceeded beyond vascular turgescence; which, by pressure and interruption of the circulation, is capable of producing the worst symptoms (convulsions, coma, paralysis, &c.); yet, as the brain is not disorganized, the vascular congestion is susceptible of removal. An amelioration in the advanced part of the second stage, or later, ought to inspire less sanguine hopes; as effusions of serum, lymph, and pus, may have taken place, and may not admit of absorption.

<sup>a</sup> “Cyclopædia of Practical Medicine;” Volume I; Pages 306 and 307.

or, if the case be cerebritis, the effect may have been softening;—a highly intractable affection.

*Unfavourable Symptoms.*—The unfavourable symptoms are—a continuance, notwithstanding suitable treatment, of headache, heat, delirium, and watchfulness; or of coma, convulsions, strabismus, spasmodic rigidity, palsy, and a slow irregular pulse: finally, the mortal symptoms; namely, an exceedingly rapid and feeble pulse; relaxation of all the sphincters, including the “orbicularis oculi;” singultus; aphonia;<sup>a</sup> dysphagia;<sup>b</sup> general muscular relaxation, with inability to move; collapsed cadaverous countenance; &c. Of chronic inflammation of the brain, or acute becoming chronic, the prognosis is always doubtful; and the friends should be apprised, that the disease may induce epilepsy, paralysis, mania, insania, or idiocy.<sup>c</sup>

## SECTION VII.—‘TREATMENT’.

*Blood-letting.*—As to the general treatment of phrenitis, it is perfectly easy. In the first place, we should have recourse to copious blood-letting; and my own experience leads me to think, that bleeding in the arm is just as good as bleeding in the neck. It is not advisable to bleed from the temporal artery, because we have to put a bandage on the head afterwards; which occasions more or less augmentation of the heat; and the bandage itself is often very troublesome. With regard to opening the jugular vein, that sometimes causes so much agitation of the patient, that it is not a very easy matter to accomplish it; but there is no difficulty in detracting blood from the arm; and, besides, I am not aware that there is any particular *advantage* in taking blood from the head. If we make a large orifice in the arm, make the patient stand upright, and produce a strong impression, it will generally answer every purpose.

*Cold Applications and Quiet.*—Cold should be applied to the head. A bladder of ice laid upon the head, and a stream of cold water allowed to run upon it, are both very serviceable. In a case of violent phrenitis, evaporating lotions are hardly sufficient; and it is better to apply ice, or a stream of cold water. The posture of the patient should be carefully attended to. The head should be raised as much as possible; and silence and darkness are indispensable.

*Purging, Colchicum, Antimony, and Mercury.*—I need not say, that active purging is likewise required; and we may give antimony, colchicum, or mercury. Antimony is a very good remedy, if given so as to keep the patient in a state of constant nausea; colchicum, likewise, is excellent;—on account of its depressing the whole system, producing nausea, and purging the patient violently. But altogether, as I said<sup>d</sup> when speaking of the treatment of inflammation in general, I should place the greatest reliance on mercury; and should get the mouth sore as quickly as possible.

*Blisters and Low Diet.*—Sinapisms to the feet may likewise be exceedingly useful; and, after free bleeding, a blister applied to the nape of the neck may be advisable. But blisters are, generally, dangerous remedies. After a time, if the inflammation be not very violent, a blister may be applied to the forehead; but it is not till towards the close of the disease, that I would recommend any blisters to be applied to the crown of the head. I need not say, that the patient ought to be starved; and that rest should be strictly enjoined. If the disease have arisen from the cessation of another disease, we ought (if possible) to re-excite the latter. If it have arisen from the cessation of gout or rheumatism, we ought (with this view) to apply sinapisms to the extremities.

*Digitalis.*—I certainly would not give digitalis in such a case; for it is a narcotic that frequently produces irritation of the brain, when exhibited for other affections; and not only so, but it is much less to be depended upon in inflammatory

<sup>a</sup> From α (primitive), *without*; and φωνη, *the voice*.

<sup>b</sup> From δυσ, *with difficulty*; and φάγω, *to eat*.

<sup>c</sup> “Library of Medicine,” Volume 2; Page 54.

<sup>d</sup> See Page 127.

cases, than other medicines. It will, moreover, frequently produce delirium or headache.

*Inflammatory Headache.*—In chronic inflammatory headache, the same treatment is required; but it should be carried on, of course, with less vigour. It is astonishing what perseverance in bleeding is sometimes required, in order to effect a cure in these cases. Blood must be taken every week or ten days;—either from the arm, or by cupping, or by leeches. The application of cold, of blisters to the nape of the neck and to the forehead, and likewise setons in the neighbourhood of the neck, are all useful. The disease often gives way to mercury, as soon as the mouth is tender. I have seen this in dozens,—I might almost say *hundreds* of instances. Bleeding did good to a certain extent only; but as soon as the mouth became sore, away went the pain. I need not insist upon low diet, and attention to the state of the bowels.

*Blood-letting from Distant Parts.*—In some cases, however, which have proved rebellious to starvation, the application of cold, setons, frequent bleedings in various ways, and pyalism long continued, I have seen the disease yield rapidly, on taking away blood from a more distant part. I have seen several cases in which, on applying cupping-glasses no longer to the nape of the neck, but to the hypochondrium, the disease has rapidly given way. Some recommend them to the verge of the anus. I have been surprised, on some occasions, to see the disease decline immediately, when cupping was instituted on the abdomen.

*Treatment in Vertigo.*—The same perseverance in bleeding is frequently necessary, when the phrenitis or inflammatory state of the head is not characterized by *pain*, but simply by *giddiness*. I have seen some cases of intense vertigo (in which there was sufficient strength of body to bleed freely) ultimately give way to that measure. In instances where I could not make out any sympathy with the stomach and intestines, but where it appeared to be an inflammatory state,—the chief symptom of which was vertigo; or where that was almost the only symptom, except throbbing of the head, on motion or taking stimuli,—I have seen continued depletion effect a cure. If patients feel themselves worse for stimuli, and the pulse is sufficiently strong, I would certainly bleed.

I recollect a case of severe vertigo, in a young man, attended by no other symptom whatever; and, as he was young and strong, I bled him to between twenty and thirty ounces, with no relief whatever, but with no aggravation of the symptoms; and I was obliged to have recourse to this extensive bleeding several times, before he was cured. He had been ill, from this giddiness, for many months; and used to roll about the room with it; but he recovered simply by repeated bleedings to this extent. It is just the same sort of case, as chronic inflammatory headache; only that these symptoms arise from the particular part of the head, which the inflammation has attacked.

I had a case, a few years ago, in which this vertigo was acute. A young woman was suddenly seized with intense giddiness; but without any pain. There were some very odd symptoms about her. Her eyes were pushed far more forward in the orbits, than in health; and every event appeared old to her;—so that there was an extraordinary affection of the brain. If she put down a tea-cup, she fancied that it was years ago; and she could not get over this feeling. These were her symptoms; and, as she was plethoric, and her pulse justified bleeding, she was twice depleted very copiously; and, by that simple means, together with purging, she got completely well. There was no pain whatever in this affection.

*Vertigo depending on an Opposite State.*—It is to be remembered, however, that all these affections—whether there be an inflammatory state of the head, or inflammatory headache, or simple vertigo—may depend upon an opposite state of the brain. I have seen several cases of chronic pain of the head, which have resisted all anti-inflammatory treatment; but which gave way very speedily to the exhibition of iron, quinine, or other tonics, and to full diet. We can only judge of these things by observing, not only how long the case has existed, but that the pulse is feeble, and that stimulating the patient does not make him worse. If this

be the case, we may safely resort to an opposite mode of treatment; and I believe iron is the best remedy we can employ. In other cases, it is well to apply cold, in the form of a shower-bath; which is a powerful tonic. This state appears to be a morbid sensibility, without any great accumulation of blood; and certainly without any violent action of the brain. With respect to vertigo, I recollect seeing a gentleman, who had a constant sensation as if he were going to fall forwards;—a sense of plunging as he sat in the chair. He had no pain at all; but he had heat: and the throbbing sensation in his forehead was terrific. He was upwards of sixty years of age; but he had a florid complexion, and was a strong old gentleman. It seemed to me, that the case required antiphlogistic treatment; and I recommended that it should be put in practice, and that his diet should be low. I may mention, that he was a very excitable person; that although he was so old, he said he had not lost any of his vigour; that since he was twenty-five he had not experienced the least change; and that in hot weather he experienced the strongest excitement. In general, people are not so sensitive at that age; but the slightest effects of various agents were distinctly perceptible to him;—in fact, such agents as would not have affected other individuals. Seeing all this, and that there was such extraordinary excitement within the head, I concluded that though he had no pain, yet the case was certainly of an inflammatory nature. Antiphlogistic measures were put in practice; but, as I understood, without the least benefit. He was afterwards allowed meat, wine, and stimulants of all kinds; and I was told that he got perfectly well. Here was an instance of vertigo of an opposite kind. It was difficult for me to form an opinion, though I had paid great attention to these diseases; and I formed a wrong judgment. I thought antiphlogistic treatment would be best; and it is possible that the other mode might not have succeeded, if anti-inflammatory treatment had not been put in practice first. We may have inflammatory pain of the head, of a nature to be benefited rather by stimulants and tonics, than by depletory measures; and we may have these partial symptoms of affection of the head;—such as vertigo; which must be treated in the same way.

*After-Treatment.*—It is to be remembered that, after the acute disease, we may have a state in which nourishment, and even opium, are the chief remedies. At the close of phrenitis, especially if the evacuations have been copious, there sometimes will be a continuation of delirium; and if the evacuations be carried to a greater extent, they will kill the patient; and sometimes this state will come on, without any previous active inflammation. In such a case as this, opium is the proper medicine; and, for the most part, the patient's diet must be good; but of this I will speak hereafter, when I come to consider that affection occurring within the head, which has been called "delirium tremens." As it has received a particular name, I will speak of it separately; but it is a state which will occur without any great tremor, at the close of common inflammation of the brain.

---

## CHAPTER II.

### HYDROCEPHALUS.

[UNDER this term was formerly comprehended every preternatural effusion of serous fluid in the region of the head;—whether external to the cranium, or contained within it. In process of time, however, it became limited to effusion occurring within the cavity of the skull. Systematic writers have laid it down, that such effusion may occur either between the cranium and dura mater, into the great cavity of the arachnoid, in the sub-arachnoid cellular membrane, or (finally)

into the cavity of the ventricles. But hydrocephalus,<sup>a</sup> in the more restricted sense in which it is usually understood in this country, means a serous effusion taking place into the ventricles, or (which is a much rarer occurrence) into the sac of the arachnoid.<sup>b</sup>]

### SECTION I.—HYDROCEPHALUS ACUTUS.

This is another instance of inflammation of the brain;—causing, for the most part, great effusion; and as this effusion was formerly noticed more than any thing else, the disease does not go, or has not gone, by the name of “inflammation of the brain;” but has received the peculiar appellation of “hydrocephalus acutus.” Some who have been more precise in their language, have chosen to say “hydrocephalus;” and some have called it “*phrenitic* hydrocephalus.”

*Mostly occurs in Infancy.*—It is a disease seen, in the greater number of instances, in children. In fact, it particularly occurs in the phrenitis of children; but the phrenitis of *adults* is sometimes attended by very copious effusion. When a child has inflammation within the head, it usually goes by the name of “hydrocephalus acutus;” but in its essential character, it is very much the same as the common phrenitis of adults.

*Premonitory Symptoms.*—It frequently comes on, in children, after heaviness of the head, dullness of the mind, and a disturbance of sleep; the child frequently has frightful dreams, wakes screaming, is found to be restless both up and in bed, and to be exceedingly peevish in temper. There is, likewise, a continual knitting of the brows; which is a common symptom in inflammatory states of the head. The child, too, is frequently observed to walk insecurely;—to totter a little; as if it experienced a certain degree of vertigo. Some say they have observed children, in these circumstances, have a great trick of putting their hands behind their head, and pulling the back of their neck. There is occasionally darting pain in the head; and there is feverishness. The body is hot; and the pulse is quick,<sup>c</sup> and exceedingly various. From feverishness, the child’s nose and lips are dry; and this gives rise to a degree of itching;—so that the child is continually picking his nose and lips. Of course there is thirst, and loss of appetite; and frequently there is fetid breath. The stomach and bowels are disturbed; the tongue is white, yellow, or brown; nausea is experienced, and also vomiting and costiveness; though occasionally there is purging and griping. The fæces are observed to be white, and to have a sour smell; though, on the other hand, they are sometimes dark and very fetid. The abdomen is frequently full, especially at the epigastrium; and there is frequently tenderness on pressure; but this is particularly noticed at the epigastrium, and the right hypochondrium.

These premonitory symptoms may go off spontaneously; and if the practitioner attend to them, he may remove them; so that nothing follows. Whenever we see such symptoms as these, we must recollect that they may be easily followed by hydrocephalus; and it is our duty to attempt to remove them. This may generally be accomplished; but if we fail, and hydrocephalus does come on, we have, at any rate, done our duty. It is true that hydrocephalus might not have supervened; but it was impossible for us to tell that; and it is our business to do what we can to prevent it. These symptoms may last only a day or two, and then come on with increased severity; or they may last many weeks.

[Dr. Yeats,<sup>d</sup> who has made the earlier stages of this disease his particular study,

<sup>a</sup> From ὕδωρ, *water*; and κεφαλή, *the head*.

<sup>b</sup> “Cyclopædia of Practical Medicine;” Volume 2; Page 452.

<sup>c</sup> This remark is somewhat at variance with the opinions of Gölis, and other subsequent writers. Gölis states that “the pulse, which deviates little or not at all from its natural quickness, is found, on an attentive examination, to beat oftentimes a few beats weaker, and sometimes to intermit altogether. It is commonly the seventh, ninth, sixteenth, seventeenth, or one-and-thirtieth beat, which the finger feels weaker, or not at all.” (Gölis, on Acute Hydrocephalus; translated by Dr. Gooch. Page 12.)

<sup>d</sup> “Statement of the Early Symptoms which lead to the Disease termed ‘Water in the Brain.’ By G. D. Yeats, M.D.”

places among the premonitory symptoms occasionally present, tenderness in the scalp, stiffness of the neck, increased sensibility of the eyes to light, and in some rare cases severe earache. He also draws attention to the remarkable change from the healthy appearance which the countenance undergoes, the transient paleness and occasional collapse of the features, the dulness and loss of expression in the eyes, and the dark line under them. A teasing cough is sometimes present. There is an unusual tendency to constipation. If aperient medicines be given, the consequent evacuations are both harder and less abundant than they were wont to be from a similar dose. In colour they are sometimes lighter than natural, and at other times tinged of a dark greenish hue, and accompanied with a slimy matter.

Dr. Cheyne has the merit of having been one of the first writers who strongly directed the attention of the profession to the derangement in the functions of the liver and of the alimentary canal, which so often precedes, and not unfrequently seems to excite, this affection of the brain. The proportion of cases in which the diseased action commences in the abdominal viscera is, he thinks, very considerable. He was led to this belief, partly, by having observed how usually derangement of the above-named organs precedes hydrocephalus; partly, from the remarkable benefit which, in the early stages of the affection, so often ensues upon the use of active purgatives; and, finally, from the frequency with which unequivocal marks of disease are discovered in the liver or intestines on dissection. In the incipient stage, or while the disease of the brain is as yet only forming, the colour of the stools indicates an inactive state of the liver; while, at a subsequent period, when hydrocephalus has become fully established, the bile seems to be both vitiated, and in excess. The intimate sympathy which exists between the brain and the liver, is well known to surgeons; and that between the brain and the stomach and intestines, is familiar to every one. When we consider the close and unquestionable sympathy which subsists between the head and the digestive organs, and take along with this the greater exposure of the latter to irritating causes and consequent functional derangement, we are disposed to think that the now very generally received opinion, as to the frequent origin of hydrocephalus in abdominal disorder, is well founded. How this connection is to be explained, matters little. The comatose state in which inflammation of the mucous membrane of the bowels in infants (about the period of weaning) often terminates, is a striking instance of this origin of cerebral derangement. A remarkable diminution of the urinary secretion, frequently precedes the oppression of the brain; and may possibly sometimes, as Dr. Abercrombie has suggested, be in some degree connected with it.<sup>a</sup>]

*Stages.*—When the disease is formed, it has two stages; and it may occur without any premonitory symptoms. Not only may the latter vary in duration,—from a day to a few weeks; but they may last only for an hour or two, and, indeed, they may not exist at all; for the child may be seized in a moment.

*Symptoms of the First Stage.*—When the disease occurs, there is a severe pain in the head,—shooting through it; so that the child lays its head in its mother's lap; and is continually crying—"Oh, my head!" It is awakened, too, from sleep, by this violent shooting pain in the head. The latter is found to be very hot; and there is intolerance of light and sound; and, from the sensibility of the retina, the pupil is very much contracted. From the extreme irritation of the nerves, I presume, there is strabismus; but some ascribe this to *paralysis* of certain nerves;—so that some muscles get the ascendancy over others. However, it appears before there are any signs of paralysis;—during the mere excitement of inflammation. Besides the squinting, there are convulsive spasmodic motions of other muscles; and frequently there are general convulsions. Sometimes there is delirium at last, but sooner in some cases than in others; and the delirium may not be constant. In the first instance, it is *not* constant. The child is observed to turn its head continually about on the pillow;—never to be at ease; and there is a peculiar motion of its arms; so that it saws the air with its hands, and tosses them

<sup>a</sup> "Cyclopædia of Practical Medicine;" Volume 2; Pages 453 and 454.

over its head. Whenever we observe these symptoms, we may be sure that the disease is formed. There is now violent pyrexia; the pulse is rapid and full;<sup>a</sup> and Gölis says that the abdomen sinks, and becomes flatter; and that this is a pathognomonic sign of the disease;<sup>b</sup> so that if this occur, we may be certain as to the nature of the disease. Whether he is correct, I cannot tell. There is, in this stage, costiveness; and the stools are usually very fetid, and of a very dark colour:—something like tar. About this time, the abdomen (especially the epigastrium, or the right hypochondrium) is exceedingly tender; and the vomiting which occurred as a premonitory symptom, is now perhaps very frequent. These symptoms, like the premonitory, may exist for various periods; but, of course, they cannot exist so long as the premonitory symptoms may. They may last only a few hours; or they may last a day or two; or they may be extended to seven days; but I believe they very seldom go beyond that.

*Symptoms of the Second Stage.*—After this, comes on the second stage; which is that of exhaustion. There is now more or less blindness; and the child is unable to discern one object from another; and perhaps it cannot perceive the light, which is now borne very well. There are no longer twitches; the pupils are no longer contracted, but dilated; and sound no longer produces disturbance, but appears not to be heard. There is a general insensibility; and the child, from being delirious and irritable, is now drowsy; and the convulsions come on with more intensity; as likewise does the squinting. The pulse is no longer quick, but weak and slow; and, in fact, an apoplectic state occurs. There is sometimes hemiplegia, or local paralysis of the limbs; and there is likewise paralysis of the eyes. Sometimes the two stages are very distinctly marked; but they certainly run into each other; so that both may exist together in a limited degree. This may last for three weeks; but it rarely, I believe, extends much longer. The first stage does not subside entirely, but there is a great diminution of it; and the second stage comes on, but is not fully formed. The first stage, without the second, rarely extends beyond seven days; but when the second stage begins before the first has come to a close, the two may continue together for two or three weeks. Now and then the pulse is quick throughout the disease; and when the apoplectic state comes on, the pulse is as rapid as before, or very rapid.

*Symptoms of the Third Stage.*—It has been observed, that before death, after the second stage has been fully formed, there are again symptoms of excitement; so that some writers have divided the disease into three stages. But this, I believe, does not occur very frequently. Now and then, however, there is excitement; and the pulse, after it has been slow, will become quick. There will appear to be some sensibility of the eyes and ears. Even the muscular powers, which have been implicated, will be partially restored; and likewise the mind: so that not only the delirium, but even the stupor, will pass off; and the child again knows its friends and parents. Some of these symptoms will occur without the others. Occasionally the mind will be restored to a certain extent, and the senses return; and yet the pulse will continue low. Now and then the pulse will be rapid; and no other change occur. But, now and then, this restoration of the powers of the mind, and the powers of volition in the muscles, will take place where great effusion is found after death; and where there is every reason to believe that effusion existed, at the time that this restoration occurred. The common people term this “a lightning before death;” and we observe, in many diseases, an apparent amendment just before the fatal event. But when this last change does occur, the pulse generally becomes very rapid; and for the most part, whatever restoration there may be, there is observed more or less stupor; and perhaps convulsive actions.

<sup>a</sup> Gölis says—“The pulse is now like that of an old man;—slow, unequal, and intermittent;” and he regards it as a pathognomonic sign in this (the inflammatory) stage, in complicated cases. See his “Treatise on Hydrocephalus Acutus” (Gooch’s Translation); Page 26.

<sup>b</sup> See “A Treatise on the Hydrocephalus Acutus, or Inflammatory Water in the Head. By Leopold Anthony Gölis; Physician and Director to the Institute for the Sick Children at Vienna. Translated by Robert Gooch, M. D.” Page 24.

*Water-Stroke.*—The disease occasionally occurs in a moment; and when that is the case, from the idea of water being so prevalent among medical men, it has been called, by Dr. Gölis, “wasserschlag,” or “water-stroke.”<sup>a</sup> But it is to be remembered, that children sometimes die from this disease without effusion taking place; and, on that account, “arachnitis” would, I think, be a much better name than “hydrocephalus.” Sometimes, in a moment, a child will have a rush of blood to the head; it will breathe hard, and die; and, after death, a great collection of blood may be found in all the vessels of the head. The disease sometimes, when it terminates, leaves more or less paralysis; sometimes it will leave hemiplegia; and some patients have recovered with paralysis of one arm, or of one leg.

*Morbid Appearances.*—After death from hydrocephalus, the same marks of inflammation and congestion in the brain and its membranes may be present, as those which are met with in phrenitis. Sometimes we find nothing more;—so that the squinting, the dilatation of the pupils, and the coma, are not necessarily the result of *effusion*. There may be no effusion whatever; notwithstanding that the child has died from hydrocephalus; and, before death, there were strabismus, dilated pupils, and loss of consciousness. Death will arise from the mere irritation and excitement which the child has undergone; and from the compression, and perhaps fulness of the vessels; but it is not necessary that there should be compression from effused fluid. Frequently we find the same congested and inflammatory state on the scalp, that there is within, and a great deal of serum is effused;—just as has been occasionally observed in common phrenitis.

But sometimes no such appearances are present. I have myself opened children who have died of this disease, and have found nothing;—the congestion and the signs of an inflammatory state having subsided, I presume, after death; and the blood having left those vessels in which it ought not to have existed, and returned to its usual route. It is possible for even the marks of inflammation to cease after death, before the body is examined.

*Characters and Seat of the Fluid.*—If, however, there be fluid, it varies very much as to its clearness. Sometimes it is perfectly limpid and uncoagulable. It will be found, of course, *in* the brain or *upon* the brain; and its quantity is generally from two to six ounces. The brain at large is sometimes found œdematous after this affection; especially at the “corpus callosum,” the “fornix,” and the “septum lucidum;” and this œdematous state exists either alone, or in conjunction with ventricular effusion. In infants there is great ventricular effusion, at the same time with œdema of the brain; and not unfrequently the same circumstance is noticed in adults; but it is generally seen in infants. The brain, after this disease, is very often found soft in particular parts (from the inflammation); and it is not an uncommon thing to meet with scrofulous tubercles in the brain itself, or its membranes:—showing the predisposition to disease in the brain. These, of course, existed before the hydrocephalus was set up; but they show the tendency to disease of the brain.

The longer the disease has lasted, the greater in general is the turgescence of the vessels, and the softer is the brain;—at least according to Dr. Gölis;<sup>b</sup> who has had more experience, I suppose, in this disease than any one else. He also mentions<sup>c</sup> that effusion will sometimes take place in a very few hours. Now and then, we have marks of inflammation in the liver and in the intestines. It is not by any means uncommon, for an inflammatory state of these parts to coexist with hydrocephalus.

*Causes.*—This disease, as I have already stated,<sup>d</sup> is for the most part an infantile disease. Sometimes it occurs about puberty, sometimes afterwards; but it chiefly affects children from two to ten years of age. It is an affection that very much runs in families; so that we may meet with some who have lost several children by

<sup>a</sup> See his “Treatise on Hydrocephalus Acutus” (Gooch’s Translation); Page 5.

<sup>b</sup> See his “Treatise on Hydrocephalus Acutus” (Gooch’s Translation); Page 183.

<sup>c</sup> At Page 19 of his “Treatise on Hydrocephalus Acutus” (Gooch’s Translation).

<sup>d</sup> See Page 501.

hydrocephalus. It frequently succeeds other acute diseases, especially whooping-cough; now and then (*frequently*, indeed) it occurs during teething.

*History.*—Hippocrates speaks of water in the brain; and mentions many symptoms of acute hydrocephalus; but this particular disease was only first accurately described by Dr. Whytt, in 1768. He gives a full description of the inflammatory symptoms.<sup>a</sup> Dr. Cook, in his work on Nervous Diseases, states that Dr. Gregory used to say it was described by a surgeon at Glasgow, in 1753; and that M. Petit, a celebrated surgeon at Paris, gave many of the symptoms in 1718. But its description was not thoroughly given, till the latter part of the last century.

*Prognosis.*—Our prognosis ought to be exceedingly cautious, even during the premonitory stage. It ought to be still more cautious in the first stage of the disease itself; and it ought always to be unfavourable in the second stage, although this is sometimes recovered from: and so, it is said, is even the third stage, when excitement takes place. It is said to have been recovered from spontaneously; but I have never seen it. However, children have actually recovered from the disease in the very last stage. Even by medicine and the best means, recovery is very rare; and perhaps a favourable issue occurs quite as frequently by the spontaneous efforts of nature, as by art. Indeed, to show that the disease may be recovered from by a child apparently in the most hopeless state, it is said that there is no one symptom which indicates death with certainty, excepting slow breathing.

*Treatment.*—The disease is clearly inflammatory; and the treatment of inflammation is that which is demanded for its cure. From the effusion which is generally produced by the disease, one would suppose that there is an inflammation of the arachnoid. The fluid which is effused in greatest quantity, is found in the ventricles lined by the arachnoid, and upon the brain in the cavity of the arachnoid; and, therefore, one would suppose that the chief seat of inflammation is in that membrane. The effusion, I need not say, is the mere result of inflammation.

*Treatment of the Premonitory Symptoms.*—During the *premonitory symptoms*, we have first to empty the bowels well, and, for this purpose, calomel in full doses answers better than any thing else;—at least, it is best to lay a foundation with it; and then to carry it off by another purgative, such as castor oil. It is always best, in the first instance, to premise a dose of calomel. Other purgatives then answer to a certainty; and the bowels are well cleared. This open state of the bowels is to be preserved by doses of mild purgatives, such as castor oil, repeated from time to time. Perhaps one or two very full doses of calomel would be advantageous. If the calomel should operate too much, it might be useful to give small doses of Hydrargyrum cum Cretâ; but the proper treatment is certainly to empty the bowels well; and, if requisite, to give mercury in repeated doses, for the purpose of producing a mercurial action on the system. If there be any tenderness of the abdomen, this of course should be carefully attended to; and leeches should be occasionally applied. In such a case, it would be well to avoid giving acrid purgatives;—lest we increase the inflammatory state; and, if mercury be still given, it should be in the form of Hydrargyrum cum Cretâ; or castor oil may be exhibited from time to time, in order to empty the intestines. Wherever the abdomen is tender, there leeches should be applied. The warm-bath is useful in almost all diseases of children; but, to render it advantageous, it should be employed twice a day; and I should think it an excellent remedy in the premonitory stage of hydrocephalus. The diet should be mild; and leeches should be applied to the head, from time to time. If all this be done, we shall very probably get rid of the morbid state; and the disease itself will be prevented.

*Treatment of the First Stage.*—But when the disease is *fully formed*, and not merely *hanging over* the patient, then we must act with the greatest vigour. We have an acute inflammatory complaint to treat; and therefore we must bleed freely and early; and it is admitted, on all hands, that we should exhibit mercury with the greatest freedom. Those who are not aware, or do not attend to the circum-

<sup>a</sup> "Observations on the Dropsy in the Brain. By Robert Whytt, M.D."

stance, of the power which mercury occasionally exercises over an active inflammatory state of the system, all allow that in this disease it is of the greatest use. In the treatment of this disease, all persons praise mercury. As to bleeding, it is a very good practice to open the jugular vein, or a vein in the arm, if the child be old enough. Abundance of leeches should be applied to the head; while we should carefully attend to the abdomen; and if there be tenderness, we should apply them there likewise. Very large doses of calomel are borne in this disease;—both from the circumstances of the disease being of a highly inflammatory nature; and subsequently, in the second stage, from the whole system being in a state of torpor. During the compression of the brain, or the softening of it, very large quantities of calomel are admissible. The bowels, I need not say, ought to be thoroughly cleared several times a day; and mercury given as rapidly as possible. The bowels will bear many doses of calomel in the twenty-four hours; but if, from their irritability, they will not bear calomel, we must try whether Hydrargyrum cum Creta will answer better; or we may lose the mercurial effect. It is a good practice to rub mercurial ointment into the parts, as fast as it can be done. The patient should be kept as upright as possible; and it is desirable, if the child be hot, to apply cold to the head; and, in these cases, ice is the best application. After proper bleeding, local and general, sinapisms or blisters may be applied to the abdomen. In the latter stage of the disease, a blister to the nape of the neck, or the warm-bath, may still be of use; but we cannot expect great benefit from them, in such an active inflammatory disease as this. A bladder of ice should be kept on the child's head, while it is in the bath.

*Treatment of the Second Stage.*—In the *second stage* of the disease, when there are signs of torpor and paralysis;—when the pupils are dilated, and the patient cannot see;—when the pulse is perhaps slow, and the apoplectic symptoms prevail;—the same plan should be pursued, according to the strength of the patient. If the inflammation be still going on, the signs of compression may not arise from effusion, but from the great congestion of blood;—at any rate, the inflammation may still exist. When leeches can no longer be applied, still we may continue the exhibition of mercury, and antiphlogistic treatment, as far as possible. We may now apply a blister to the whole head: there is no danger whatever from it, in this stage of the complaint; and it frequently does great good. When all these things have failed, it is said that some children have recovered by the use of elaterium;<sup>a</sup> and others by the employment of digitalis and squills. If any thing of this description be given, it should be in small and repeated doses. If elaterium be given with the view of exciting an evacuation of fluid, it is best to put a grain into two ounces of liquid; and, if the effusion be going on, to give the child a teaspoonful of the mixture, every now and then, till it operates in the way desired. As to digitalis and squills, it is best to give them in small and repeated doses. I never myself recovered a child in this state; but different persons have told me, that they have seen a child so recovered.

*Treatment of the Last Stage.*—In the *last period* of the disease, opium has been given with advantage;—not for the purpose of cure, but to procure sleep and tranquillity; and it has never been productive of harm. In the latter part of the disease, it may be necessary to give good nourishment, in order to support the patient; and even stimulants may be required; for, after the disease has existed for a length of time, we may have a state of irritation of the brain, arising from mere debility. The inflammation may have all subsided; and an opposite plan of treatment to that which was at first imperiously necessary, may be required.

[Not only is it now well understood that the great mass of cases formerly known as acute Hydrocephalus, are really dependent upon meningeal inflammation, but of late years it has been further established, that this inflammation is commonly connected with a deposit of granulations, which there is every reason to regard as tuberculous. This circumstance has led to the division of meningitis,

<sup>a</sup> From ελάνω, to agitate.

into simple and tuberculous. The seat of this deposit is in the pia mater; where they are met with in the form of small white granulations, principally along the course of the vessels in the fissures of Sylvius, or disseminated at the base of the brain and around the annular protuberance and the peduncles. At the same time, tuberculous depositions may usually, if not always, be discovered in other parts of the body, especially in the lymphatic glands in children, and in the lungs in adults. The connection between this form of meningitis and tuberculous deposits was first clearly made out by Drs. Gerhard and Ruzf. It differs from simple meningitis in several important particulars. It is met with at all ages, but is particularly frequent between the ages of two and fourteen. It is not common in early infancy, before the first dentition is accomplished; a period in which, on the other hand, simple acute cerebral irritation or inflammation is frequently met with. The latter is sudden in its onset, and in early infancy is often the result of intestinal disorder, of dentition, &c., or occurs in the course of other diseases. These cerebral disorders of very early childhood, are moreover rapid in their course, usually terminating in death or recovery in a very short time. The commencement of tuberculous meningitis, on the other hand, is usually more insidious. Upon strict inquiry, we shall often find that the attack has been preceded from time to time by some slight cerebral or nervous symptoms. When the inflammation is fairly formed, it is rather of a sub-acute character, and comparatively slow in its progress, terminating, in the great majority of cases, in the course of the second or third week. The symptoms dependent upon the inflammation of the membranes are of course much the same, whether it be tubercular or not; their gradual increase and succession being the chief characteristic of the former. The diagnosis, however, may in most cases be established with tolerable certainty by a careful consideration of the circumstances under which the attack arose, the mode of its commencement, the age and constitution of the patient. Thus, if we meet with a case of sub-acute meningitis in a child who has already completed the first dentition, where the attack has not been suddenly developed in the midst of perfect health, under the influence of some evident accidental physical cause, such as severe injury to the head or prolonged exposure to the sun, but on the contrary has been preceded by evident signs of ill health, there is strong reason to suspect that it is tuberculous. If, in addition, we find evidences of a scrofulous or tuberculous tendency in the constitution, whether hereditary or acquired, the diagnosis assumes a degree of certainty which the subsequent course of the disease will scarcely fail to confirm. The ordinary causes of inflammation may, of course, become the exciting causes of tuberculous meningitis, but still their influence here is much less decided than in the simple form of the disease. The former, indeed, is essentially connected with a general tuberculous diathesis. Its prognosis, of course, is very unfavourable; recovery, indeed, being a rare occurrence, after the disease is fairly formed. To the prophylactic measures, therefore, we should direct especial attention. Thus, in children of a scrofulous or tuberculous habit, and especially where the disease is known to be hereditary, every precaution should be taken to prevent excitement of the brain, until towards the period of puberty, when the tendency to the disease is much lessened. At the same time we should endeavour to improve the general health by all those hygienic and other measures which are adapted to the tuberculous diathesis. As regards the treatment of the inflammation, when fairly formed, it is much the same as in simple meningitis.—T. S.]

## SECTION II.—CHRONIC HYDROCEPHALUS.

There is another form in which water or serum is collected within the head. When speaking of inflammation and its effects, I stated that effusion was commonly the result of inflammation of serous membranes;<sup>a</sup> but I also stated, that

<sup>a</sup> See Page 94.

effusion in a serous membrane will take place frequently with a very slight degree of inflammation;<sup>a</sup> and sometimes there is scarcely any to be discovered;—perhaps there is none;—at least, we are justified in saying so. The same is the case with respect to sweating. A person may sweat, in acute rheumatism, from the intense heat of the body; but a person will also sweat in the agonies of death, and in extreme debility. So with regard to purging. Purging frequently depends upon an inflammatory state of the mucous membrane; but, in other cases after death from purging, no inflammation can be discovered; and the person has been free from tenderness during life.

*Nature.*—Chronic hydrocephalus illustrates these general remarks. In chronic hydrocephalus, there frequently is no sign of inflammation to be discovered; sometimes there is. Sometimes it is pure dropsy, independent of inflammation;—at least, there is no inflammation that can be made out; and it is a very slow disease. Sometimes the affection is connate;—born with the patient. Sometimes it does not appear before the first or second year; and it has continued during a tolerably long life. A patient has lived with dropsy of the head, till he had attained his fifty-fourth year. Gall and Spurzheim mention the case of a woman who arrived at this age, in whose head four pints of fluid were found; and the patient did not then die of that disease, but of enteritis.

*Quantity of the Fluid.*—When the water exists in this chronic form, its amount is sometimes very considerable. In the acute disease, where the effusion is the result of inflammation, there is seldom more collected in a child's head, than from two to six ounces; but in the chronic form it is frequently so considerable, that the bones separate, and the sutures and fontanel<sup>b</sup> do not close. Dr. Baillie, in one of his plates, represents the appearance of the skull in this disease. The fontanel<sup>b</sup> are much larger than they should be; and they sometimes acquire a very considerable size. The sutures may be found distinct;—each bone in some cases being separated. These are very common appearances; and such as any one may see.

*Separation of the Bones after Cohesion.*—There is nothing at all surprising in the circumstance of the sutures gaping, and the fontanel<sup>b</sup> spreading, when the water is collected, provided the bones have never cohered; but it is ascertained that the bones and sutures will open, after they have been firmly united together. Dr. Baillie, in the fourth volume of the "Transactions of the College of Physicians,"<sup>c</sup> mentions an instance of a boy, eleven years of age, in whom the fontanel<sup>b</sup> had closed, and the bones become well united by sutures;<sup>d</sup> but in whom they all separated again. Mr. Ford, who was formerly an eminent surgeon in London, observed the same occurrence, in a boy nine years of age;—the bones separated six weeks before his death. I do not know that Dr. Baillie was aware of it; but it is to be remarked that, in Mr. Ford's case, the serrated processes were much fewer than usual;—so that the bones had far smaller points of contact, than they ought to have had; and separation, of course, would be more easy. It is most probable that, if the water had collected in persons in whom there was the natural quantity of serrated processes, the bones would not have separated. I think that, in the instances of this affection I have met with, I have made the same remark as Mr. Ford; and, such being the case, we can conceive that separation would be more easy. Until I read Dr. Yeats's book on Hydrocephalus, (in which Mr. Ford's case is mentioned,) I thought that Dr. Baillie's was the only instance on record.

Occasionally the bones do not give way. There is no dilatation of the cranium at all; and it is said that it is even smaller than natural. I presume, in these cases, the bone cannot give way; and, of course, in such instances, the brain must shrink: the bones, however, generally do give way.

*Nature of the Fluid.*—In this disease, the fluid is almost always perfectly limpid;—it is generally as clear as the purest water. On being analyzed, it is found to contain scarcely any salt, and scarcely any animal matter.

<sup>a</sup> See Page 103.

<sup>b</sup> From "fontanella," the diminutive of "fons, fontis," a fountain.

<sup>c</sup> Page 1.

<sup>d</sup> From "suo," to join together.

*Morbid Appearances.*—When it collects to a very great amount, it is usually found in the ventricles; which are thereby expanded, till the whole brain becomes like a bag. On removing the cranium, we find the brain spread out to a great extent, with the fluid collected within it; and, on making a section, we find that the brain is exceedingly thin,—not thicker than paper; and the fluid immediately gushes out. This state of the parts led to the erroneous belief formerly entertained, that in this disease the brain is destroyed;—as though the person had lived, eaten, and drunk, without a brain. However, although some made this assertion, and believed that a person lived and talked without a brain, others knew the contrary to be the case; and Morgagni reproached those who published so absurd an opinion. If the fluid be collected *above* the brain, and not *in* it, the mistake may easily be made; and it may be imagined that the brain does not exist. I was present at an inspection of this description, where a child had a very large head, and had evidently laboured under hydrocephalus. On removing the bones, cutting into the sac which contained this immense quantity of water, and letting off the fluid, there was nothing more to be seen. On looking into the membrane which contained the fluid, it was like looking into a well; there was nothing resembling brain to be seen; and it was immediately said—"Here is no brain!" But as the girl had been eating and drinking, sitting up in bed and talking, like other children, till within a few days of her death, that was impossible; and we found the brain under all this fluid, perfectly sound. There was a large cyst which had existed upon the brain, and spread itself out in every direction,—so as to produce an enormous size of the head; and there lay the brain, quite little comparatively, at the very bottom of this cyst. The distension of the cranium, be it ever so great, is generally equal in all directions; but now and then it is not so. Gall and Spurzheim say, that they saw a learned and well-educated man, with a forehead so high that it must have contained three or four pints of water; while the rest of his head was not of an unusual size. The only effect in him was, that he very often fell asleep. Now and then, the bones of the internal ear become separated by the sac; so that deafness is produced. We also observe another effect within the skull. The convolutions of the brain being enveloped by the collection of water, there is an irregular pressure upon the supra-orbital plates of the frontal bone; and therefore there is not that roughness,—that irregularity which is seen in ordinary cases. Usually, the upper part of the orbital bone consists of many depressions and elevations; but in this disease, as the convolutions of the brain are enveloped by water, the upper part of the orbital plates are generally perfectly smooth. The bones are sometimes thickened; but, in a great number of cases, they become thinner than natural. Dr. Gall mentions, that the head of persons in whom this disease exists to any extent, is generally scurfy; and, since I read the statement in his book, I have looked out for this circumstance, and found the observation to be correct. The skin of the head is generally scurfy, in some part, when the cranium is greatly distended.

*Size which the Head may attain.*—The size of the head is occasionally enormous. There was, in St. Thomas's Hospital, a few years ago, a child (named Elizabeth Phillips) who was born with a head as large as that of a child seven months old. The bones were all distinct; her hair was scanty; and there was an abundance of scurf on her head. She was fat, and as lively as other children of her age; and there was no symptom indicating the existence of fluid, except the size of her head. Though she was only eleven months old, the circumference of her head was twenty-seven inches five-eighths; from the top of the nose to the occiput, it was twenty-two inches; and from ear to ear, across the top of the head, it was seventeen inches one-eighth. Considering the age of the child, the measurement was enormous.

*Cardinal the Idiot.*—A few years ago, there was in St. Thomas's Hospital a poor man, who has now become a celebrated character; in consequence of a cast of his head having been deposited in almost every museum. His head was thirty-three inches in circumference; twenty-two inches from ear to ear; and twenty-three

inches and a half from the nose to the occiput. He was thirty-three years of age; and his cranium was ossified at the sutures. Of course the bones had separated originally; but fresh bone had afterwards been deposited in the membrane between the frontal, occipital, and temporal bones;—so that he had as perfect a cranium as any one else. In him there were found as many as ten pints of water;—nine pints on the brain, and one pint in the lateral ventricles; and what was curious in him was, that the “corpus callosum” was split by the distension. An opening existed in the posterior part of the falx; through which the water (in all probability) had passed from within to without. I say—“in all probability;” because, in a great number of cases, the water is contained in the ventricles; and it is probable that, in this instance, it had made its escape. His brain only weighed two pounds fourteen ounces and a half; whereas the water in and upon the brain, amounted to ten pints.

Andral mentions, that water has been found in the fifth ventricle. I believe it is sometimes rather a quirk to ask where the fifth ventricle is situated; but there is a little space which may be called “the fifth ventricle;” and Andral says, that Broussais has found dropsy there.

*Effect upon the Mind.*—In this disease, the mind is generally weak. Sometimes there is downright idiocy; but—as the brain is only expanded, and not destroyed—there is occasionally considerable intellect. Cardinal (the man at St. Thomas’s Hospital<sup>a</sup>) had occasionally epileptic fits; and his mind was certainly weak. He prided himself on being able to say “the belief;” but he generally stumbled when he got to “Pontius Pilate.” If he were asked his duty towards his neighbour, he got on pretty well at first; but he soon made a trip; and it was also observed, that his memory was not like that of other people. He was an idiot;—at least, he was what is commonly called “a *soft* kind of person.” He was also exceedingly vain, and pretended to have violent sexual desires; and, notwithstanding his great big head, he used to try to get hold of the nurses; so that one day we heard he had been behaving very badly;—and then he would say “the belief” to you. He could walk, of course; but—being top-heavy, and having thin spindle-legs—he did so with the greatest caution, lest he should overbalance himself. Now and then, if he was not delirious, he was so ill-tempered, that we could scarcely manage him.

There is a case mentioned by Dr. W. Heberden, in the “Transactions of the College of Physicians,”<sup>b</sup> in which a chronic accumulation of water occurred in a man eighty years of age. At least eight ounces of fluid were found in the ventricles, and four ounces on the brain, after death. There was some little organic disease about the “plexus choroides;”—a solid tumour of calcareous matter; together with ossification of the basilar and internal carotid arteries, and their chief branches. Now this man, although twelve ounces of fluid were found in his head after death, had suffered nothing,—except that he had been deaf many years (which many persons of eighty are) and had vertigo once or twice,—till six weeks before his death; and then he had a fit, from which he quite recovered; and was perfectly well before he died. This shows how nature will accommodate herself to an inconvenience, if it come upon her gradually. There is a singular circumstance mentioned by Morgagni. A considerable quantity of water pressed on the brain; so much, that had it taken place suddenly, death most probably, would have occurred; but from its taking place very gradually, no further mischief was produced.

*In Acephalous Monsters.*—It is right I should mention, however, that this disease may exist when there is no brain. Dr. Gall asserted at first, that when there was water in the head, the brain was always present; but he corrected this statement, in a subsequent edition of his work; and acknowledged that people were sometimes formed without a brain. In fetuses, where there has been nothing but “the medulla oblongata,” they have sometimes had water in the head instead of

<sup>a</sup> See Page 509.

<sup>b</sup> Volume 5; Page 173.

brain;—not that the brain has been destroyed by the water; but it has been deficient by original formation; the fœtuses have been monsters.

*Very little Inflammation.*—In these cases there are generally no marks of inflammation; but we generally find, at last, that there is irritation. The vessels of the head are enlarged, and the head itself is hot. The person has more or less feverishness, and emaciation occurs; which, in the course of a year or two, is generally followed by death. In the greater number of cases, this is the course of the affection; but there are cases where no such thing occurs. In Cardinal, there were no signs of inflammation at all. He ate and drank just like other people.

*Hydrocephalus with Bifid Brain.*—In the first volume of the “Edinburgh Medico-Chirurgical Transactions,”<sup>a</sup> there is recorded a case, in which a female child, only seven months old, had a head which measured twenty-nine inches and a half in circumference; and from which there were let out, after death, one hundred and thirty-six ounces of perfectly clear fluid; such as is usually found in chronic hydrocephalus. This fluid was contained in a bag; but then the brain was split in two. When the brain is first formed, the two halves are not united; but they afterwards come together;—just as in the case of the lips. The portions of the lips, however, do not always cohere; and precisely the same occurrence takes place with regard to the brain;—so that it remains divided; and the whole of the ventricles form a continuous bag with the arachnoid, and the surface of the brain. In the case to which I have just referred, on opening the head, a ventricle was seen at the bottom;—simply from the brain not having united (as it should have done) in the progress of the formation of the body. This was merely a case of hydrocephalus;—water in the ventricles; the two halves of the brain not having united, as they ought to have done. The rest of the brain was at the bottom.

*Rupture of the Brain.*—There is, however, a very curious instance mentioned, of the actual rupture of the brain. In the case recorded in the “Edinburgh Medico-Chirurgical Transactions,” there was a deficient cohesion of the brain; but in the eighth volume of the “Medico-Chirurgical Transactions of London,”<sup>b</sup> a case is mentioned where, in this disease, there was so great a distension of the brain, that at last it actually ruptured. Both the brain and the membranes gave way, under the posterior fontanel; and an external swelling was seen to be produced;—so that the whole head became œdematous; and fluid oozed from the mouth and nostrils, for eleven months. The child lived that period, after the giving way of the brain, and even of the “dura mater;” but of course the rent must have been very local.

*Treatment: Tapping.*—In this disease, medicine (I believe) is perfectly useless; but still mechanical means have been found very beneficial. If a puncture be made, and a large quantity of fluid evacuated, the child may die very suddenly, almost immediately; but if a minute puncture be made, and a small quantity only let out at a time, it may be done with perfect safety, and the head has been known to be reduced; but I do not recollect having read of a cure till lately. I never saw a case of this kind; but it has been lately said, that some cases have been cured by a puncture being made; and a certain quantity only of fluid let out at a time.<sup>c</sup>

*Pressure by Bandages.*—Another mechanical means, also, has been of very great use; as I have, in some degree, witnessed myself;—that is, bandaging the head. It should be bandaged nicely;—so as to have a uniform pressure throughout. I believe it was Sir Gilbert Blane who first suggested, or first attracted particular notice to this remedy. He has published some cases where, if there was not complete success, yet very great benefit was derived from the plan. I rather think it is said, that some cases have been cured by bandaging. Some surgeons, instead of applying bandages, have employed adhesive plaster,—so as to confine the head; and this has answered still better. The only case in which I have had

<sup>a</sup> Page 205.

<sup>b</sup> Page 51.

<sup>c</sup> Dr. Conquest, to whom the profession is much indebted for his able and enlightened proceedings in this matter, has since published some very satisfactory cases.

any experience of this, was at St. Thomas's Hospital, in the child of an Irish woman. I directed the head to be bandaged; and it not only became smaller, but the general health was very considerably improved;—indeed, more so than the head. Unfortunately, the bandage was neglected; and the child immediately grew worse. The bandaging was again attended to particularly, and the child again improved; but I do not know the result of the case, because the mother took it away. Supporting the body, and pressure of the head by means of equal bandaging, appear to be the proper means of treatment; and, after letting out a certain portion of the fluid, I presume it would be well to employ bandaging;—thus carrying on the two plans together.

## CHAPTER III.

### APOPLEXY.

IN this intense description of sleep, there is a great diminution (or entire loss) of sense and motion; slow, laborious, and generally stertorous breathing;—a loss, indeed, of all the animal faculties. It is generally sudden; whence its name (from *απο*, and *πλησσω*, *to strike*);—the person being struck down.

#### SECTION I.—SYMPTOMS.

*Sudden Seizure.*—If a person be upright, or walking about, or sitting, he falls down; and sometimes dies on the spot. He is dead in an instant;—as if he were shot. If, however, death does not take place instantly, the pulse is generally slow and full; the face is livid and flushed, and also swollen. The lips are particularly livid; and there is generally a little froth (though not to be compared to what is seen in epilepsy) proceeding from the mouth; and a blowing, frequently, from the lips and nostrils. The lips do not act in the same way as they do when we are in moderate sleep, or when we are awake; but the air forces them open, and their elasticity brings them back again; so that the lips are constantly moved, together with the “*alæ nasi*.” The pupils are usually dilated, and the eye is insensible and closed. The cornea looks dull and glassy; the eyes are frequently bloodshot, and have a livid tinge, and so has all the rest of the face. The heat is generally increased;—especially of the head; and it is not unusual to see clammy sweats. But these almost always occur during the last period of the disease. There is at last a difficulty of swallowing. In some cases, if the attack be very severe, there is a difficulty (and perhaps an inability) of swallowing, from the very first; but, at any rate, when the disease terminates fatally, there is an inability to swallow at last.

*Seizure, with Premonitory Symptoms.*—Although this affection generally comes on suddenly, yet it is occasionally preceded, for a length of time, by drowsiness. Persons fall asleep in company, and at church, (where they will sometimes snore loudly,) even months before the fit. It is common for the attack to be preceded by headache; and by a throbbing, and a sense of tension and weight of the head. Many complain, previously, of dimness of sight and double vision, giddiness and vertigo; and, frequently, the eyes appear red before a paroxysm. Some have flashes of light (like stars) before their eyes, deafness, and tinnitus; together with dreaming, nightmare, and epistaxis.\* It is not uncommon for persons, before they become apoplectic, to have numbness of the fingers, or of one finger, or of some part of the body. Sometimes there is tingling;—in other instances, slight twitches of the muscles; and occasionally stammering. It is very common for impairment of the memory to occur; as well as more or less depression

\* From *επισταζω*, *to distil from*.

of the spirits. It is easy to conceive, that the circumstances which occasion apoplexy will, in a slight degree, cause simple headache, or throbbing of the head, or double vision, or any of the other symptoms which I have mentioned. Stammering, an inability to use the muscles of articulation properly, and a loss of memory, will also arise from a fulness of the head; and from such a state as, in greater intensity, will produce apoplexy. Sometimes, persons have hemiplegia for a longer or shorter time, before the attack; so that hemiplegia frequently terminates in apoplexy. Independently of these symptoms, the invasion of the disease is sometimes very slow. Instead of persons being knocked down, the disease will come on slowly, whether they have these symptoms or not;—so that, from being sleepy, they at last become apoplectic quite insensibly.

*Seizure commencing with Syncope.*—The disease comes on in another form which it is very important to know;—where it begins with syncope; from which the patient frequently recovers, for a longer or a shorter time, till he afterwards becomes apoplectic. This form is particularly mentioned by Dr. Abercrombie, in his very excellent work on Diseases of the Nervous System. Before the attack of apoplexy, there is sudden pain of the head;—a sharp, cutting, severe pain; but instead of the face being flushed, full, swollen, or livid, it is pale. Perhaps there is a little delirium, perhaps a wandering; but a sudden pain occurs in the head; the face is pale; the patient feels cold and faint; and there is also vomiting and purging. After this attack of syncope, the patient gets up, and may walk about;—but in a few minutes,—though sometimes not for a few hours, and sometimes not for a few days,—but after this, whatever the interval may be, coma and apoplexy gradually take place. The body then acquires its natural warmth; perhaps is as hot as in common apoplexy; the pulse is no longer faint, but becomes full and slow; and the ordinary state of apoplexy is established.

This form of the disease is almost always fatal. A rupture takes place within the brain;—not producing immediate effusion, in most cases; but sufficient to cause violent pain; and to produce such an influence on the heart, as to impair its action considerably;—so that syncope takes place; and then, after this symptomatic syncope, blood gradually oozes from the vessels, in different parts of the brain; till, at last, pressure takes place, and we have common apoplexy. It is particularly necessary to know this form of the disease, before giving a favourable prognosis. Seeing the patient is very faint, and hearing of the pain of the head, we might think nothing of it; but we must remember, that it may arise from a rupture in some part of the brain; and—in a few minutes, hours, or days—effusion will gradually take place; and that to such an amount, as to produce common apoplexy. After the latter disease, there is almost always found rupture and extravasation.

*Duration and Effects.*—When the disease does not terminate by instant death, it may last for a few minutes, or for some hours, and even days. Persons have recovered after lying in this insensible state for three days. I believe that when the state is not genuine apoplexy, but merely a symptom of what is called “nervous derangement,” in hysterical women, it may last any length of time; and persons will then recover; but if it be genuine apoplexy, persons seldom recover, if the insensible state continue beyond three days.

When the disease does not destroy life, the symptoms gradually recede, till they disappear altogether. Consciousness, perception, a knowledge of existence, and an observation of the external world, return; and the power of volition is directed to the voluntary muscles. Sometimes, however, there is not a perfect return. Power, consciousness, and perception return, except in one part of the body; so that, after the disease, one half of the body very frequently remains motionless, without being at all subject to the volition of the patient; and sometimes, in addition to this loss of power over half the body, there is also a loss of sense,—at least with regard to touch. This state may exist on both sides of the body; but it is generally more complete on one side than the other. And this state may gradually subside, or continue for an indefinite time. But there is not necessarily an entire loss of sense and motion, in this disease; for, in most cases which do not imme-

diately terminate fatally, if we pinch or otherwise molest the patient, he will evince consciousness by groaning, till within a short period of death: Frequently, too, after these attacks, the mental powers are weakened; so that the patients are never the men mentally that they were before;—never have the same power of attention,—the same memory,—the same power of mind altogether, that they had before the disease.

If the affection, however, gradually destroy the patient, the power of sensation and volition does not return. The power of deglutition, and the power of respiration remain, unless the disease kill the patient directly; but if the patient remain insensible, the power over the muscles of deglutition is gradually lost. He swallows worse and worse, till he cannot swallow at all; the pulse becomes weaker and weaker; the body cooler; respiration quicker, and at length irregular; and thus the scene is closed. The heart, however, will beat a few strokes, after the very last inspiration has taken place.

*Convulsions.*—Sometimes convulsions ensue: and I should presume that, in these cases, there is not only compression of the brain, but more or less laceration, or even inflammation. There must be some cause of *excitement*, besides the compression which produced apoplexy;—something injuring one portion of the brain so much, as to produce convulsions. These convulsions sometimes affect only one half of the body. Blood taken from the temporal artery, in this disease, is often as dark as venous blood; and the blood taken from the veins, is very often buffy and even cupped.

*Contracted Pupil.*—Sometimes, in an attack of this disease, the pupil is not dilated; but, on the other hand, extremely contracted; and there is no worse sign in apoplexy than this. I recollect a German friend of mine, who had the largest pupil I ever saw. I have frequently looked at him with astonishment. The iris never appeared larger than a thread;—forming a very fine ring. He took it into his head not to live any longer; and therefore poisoned himself, by taking half an ounce of pulverized opium. I do not know the cause of the act; but, some hours after taking the opium, he fell into a state of coma. It is a striking circumstance, that coma did not come on for a considerable time; and, as he mentioned to his friends what he had done, they sent for all the doctors they could find, and for me among the rest. He lay upon the bed; and of course we proposed giving him emetics; but he, being as much himself as any one in the room, declared we should not give him any thing. We had sulphate of copper and zinc in abundance; and endeavoured to put the solution into his mouth, and pour it down his throat; but he so kicked, thumped, and beat us, that it required a dozen of us to master him. He said that, if he thought proper to die, no person had a right to interfere with him. Finding he would not swallow what was reasonable, we got a stomach-pump; and, with great difficulty, we passed it down, and emptied the stomach; and then poured in so many wash-hand basins of water in succession, that at last the water came out as clear as it went in; so that we completely evacuated the stomach;—he, all the while, exclaiming against the barbarity of keeping in this world a man who had no desire to stay. After all this, apoplexy came on. He became senseless;—his pulse slow, his face swollen, his lips livid, and his eyes suffused; and there was also stertorous breathing. We opened the jugular vein, and a vein in the arm; bled him freely, and dashed pails of cold water on him (which is one of the best remedies); but it was all of no use. His passion, I presume, had a great deal to do with it; for he was in a violent rage to the last moment. He was sensible; and the pupil was so contracted, as to be reduced to the size of a pin's point. It would have been difficult to pass through the iris any thing of a larger diameter than a pin. I need scarcely say that he died. I believe that when apoplexy has come on from opium, and perhaps from other narcotics, a contraction of the pupil has been observed; but when apoplexy is of the ordinary kind, and has not arisen from narcotics, this symptom is mentioned by authors as being almost always a fatal sign. I never saw a patient recover, in whom the pupil was so contracted; though, of course, I have seen them recover where it was dilated. What-

ever danger there may be from other symptoms, if the pupil be contracted, we ought to give a guarded prognosis. It is mentioned, by many authors, that this state of the pupil is unfavourable; and, so far as I have made observation myself, I think the statement fully verified.

*Anomalous States of the Pupil.*—I may mention, while on this subject, that the state of the pupil, in affections of the head, is very various and very singular. When apoplexy is produced by external mechanical causes, in injuries of the head, notwithstanding the comatose state, the pupils are obedient to light and darkness;—following the introduction or exclusion of the light, just as in health. This has been observed by Sir Benjamin Brodie; who has written an interesting paper on it, in the fourteenth volume of the “*Medico-Chirurgical Transactions*.”<sup>a</sup> He also mentions having seen *dilatation* of the pupil alternate with *contraction*. At one time, the pupils were extremely dilated; and at another, extremely contracted; and this alternation had been repeated several times. He also mentions (what we might expect) that he has seen dilatation cease, when venesection was practised; and then when the effect was gone off, the pupils were dilated again. That also we should suppose. When a bone compressing the brain was elevated, the dilatation ceased. Dr. Hennen states, in his “*Military Surgery*,” (which I need not say is an excellent work,) that he has seen the pupil *dilated* when light was *admitted*, and *contracted* when it was *removed*; and Sir Benjamin mentions seeing eyes in the opposite states; that while there was a morbid *dilatation of one eye*, there was a morbid *contraction of the other*; and sometimes he has observed the pupil of *one eye only* to be dilated. These are irregular circumstances; and, as we may meet with one or all of them, it is well to know them; otherwise we might pay no regard to them when met with.

## SECTION II.—MORBID APPEARANCES.

*Occasional Absence of Morbid Signs.*—On opening the bodies of patients who have died of this disease, we may perhaps find nothing. I have seen it stated, that a person could not have died of apoplexy; because nothing unusual was found in the head, after death. But I have opened many persons who have died of apoplexy, and have found nothing that would have led me to suppose they had been apoplectic. Most probably there had been extreme fulness of the vessels during life; and, after death, the fulness had completely gone off. Sometimes there has been a retraction of the vessels; and sometimes copious blood-letting has been had recourse to; but the brain has been so compressed, that the removal of blood was not sufficient to reinstate the brain in its former powers. Indeed, we frequently find, after this disease, that the great turgescence of all parts of the face, will go off;—if not *entirely*, yet to a *great degree*; and we must suppose, therefore, that the same thing may occur internally. I recollect a patient who died of this disease. He was lying in the dead-house; but the veins looked so full and tempting, that I begged some of them might be opened, and the subject bled freely to a pint; and although the face was livid and swollen, the lividity went down, and the face recovered its former size. We may therefore presume, that a change may take place in the branches of the *internal* carotids, similar to that which occurs in the branches of the *external* carotids.

*Turgescence of the Vessels.*—But, in the second place, we may find great fulness of the vessels. The sinuses are generally filled with blood; and the vessels of the “*pia mater*” are exceedingly distended; so that they present an obvious and decided turgescence.

*Effusion of Serum.*—Sometimes we find an effusion of serum *in* or *upon* the brain. Sometimes there is simply this; but sometimes it is united with a general

<sup>a</sup> Page 325. For the facts mentioned (on Sir Benjamin Brodie's authority) in the text, see Pages 352 to 354 of that volume of the “*Transactions*.”

fulness of the vessels. It is said, that if the disease arise after ischuria renalis, serum is generally found; but I recollect opening one patient, in whom there was neither a fullness of the vessels, nor any serum effused in or upon the brain. I never opened more than one who had died of apoplexy after the suppression of urine.

*Extravasation of Blood.*—In the fourth place, we sometimes find extravasation of blood. This may be upon the surface, or in the substance; and, in the latter case, I believe it is found, more frequently than otherwise, near the ventricles. It is seldom seen in the latter alone. If we find blood effused into a ventricle, it generally arises from its having been effused into the substance of the brain near the ventricle, and projecting through the cerebral substance;—so as to make its way into this cavity. The blood may be effused, of course, in any part of the brain;—in the cerebrum, in the cerebellum, and even in the “pons varolii,” so as to lacerate it; and if it be effused near a ventricle, it frequently makes its way into it. Andral has made a large number of dissections; and states, as the result, that the blood almost always finds its way to the ventricles by rupture. Of three hundred and eighty-six cerebral hæmorrhages read of by him, he finds that two hundred and two took place in the substance of the hemispheres; sixty-one in the “corpora striata;” and thirty-five in the “thalami nervorum opticozum;” so that the hemispheres are by far most frequently the seat of hæmorrhage.

*Apoplectic Cells.*—The new cavities formed by the extravasation of blood, may be of all sizes;—varying from the size of a small pea, to that of a walnut; and, indeed, much beyond that. There is great variety, also, in the number of these effusions. Sometimes we find only one; in other instances we may find two; and in some cases we may find several. The blood which is effused, looks, at first, like currant-jelly, with a reddish fluid around it. In about a fortnight, this clot becomes much firmer; and at length it becomes soft, and has merely a reddish fluid around it. It is sometimes completely absorbed;—so that a cavity is left; and that is called “an apoplectic cell.” This cavity is sometimes lined by a new serous membrane, sometimes it contains clear fluid; and occasionally it is empty, and may remain so for a great length of time; perhaps for life. It is said, by some, that a coagulum may remain for a long time in the brain, without much mischief; but, where it does exist, it generally gives rise to paralysis.

*Apoplectic Cicatrices.*—When the process of absorption occurs, we find, in the first place, that the serum becomes absorbed; that the clot becomes firmer and paler; and then, frequently, a number of filaments are produced, running from the walls of the cavity. These filaments, at first, are loosely attached; they then become firmer; at length sometimes the cavity will shrink; all the parts will contract, and become hard together,—so that a cicatrix is produced; and this cicatrix will become very firm. Sometimes there is no cell left. The blood is entirely absorbed; a cicatrix is produced; the sides of the cavity approach together; the filaments also are contracted, I suppose; and the whole becomes quite firm. In these circumstances, there is generally a change of colour;—sometimes to green, sometimes to yellow, and sometimes to purple.<sup>a</sup>

*Cerebral Softening around the Clot.*—When there is a clot effused in the brain, it is generally found that the substance of the brain around it is softened. Dr. Baillie mentioned,<sup>b</sup> long ago, that if blood be effused into the substance of the brain, the cerebral substance around the clot is very frequently softened. Sometimes, however, there can be no doubt that a clot is the result of softening. I am quite satisfied of this from my own observation; for I have seen a person, with a pain in his head, gradually lose his memory, even have a cerebral affection, and

<sup>a</sup> Nature makes an attempt to restore the part,—just as she would in any other situation in the body. The best representation I know of these morbid alterations, is that by Cruveilhier. One of his plates depicts the progress of the changes. Fasciculus 10, Plate 8, Figure 1, represents the substance of the brain into which there has been an effusion of blood. Figure 2 represents a cavity in which a clot had formerly existed; and which, Cruveilhier says, was filled with serous fluid when he opened it. Dr. Baillie's plates are not coloured; and therefore they do not show the affection so well.

<sup>b</sup> In his “Morbid Anatomy,” Chapter 34; Section 24.

then suddenly become apoplectic and die. On examination, I have seen a portion of his brain softened like pap; and in the midst of it an effusion of blood. This is nothing more than might be supposed likely to happen. If the cerebral substance of the brain be much softened, the large vessels will at least give way, and let out blood; so that we may have a softening of the brain, through the presence of blood injecting the surrounding substance. I feel satisfied that, through the vessels becoming softened, a clot of blood may be formed; and then we have more or less apoplexy. At St. Thomas's Hospital, I opened a man who came in with hemiplegia; which is much the same thing in point of pathology. He came in with paralysis of the left side;—the arm, the leg, and the whole of the side, were paralyzed. In the posterior part of the right “*thalamus nervi optici*,” there was found a cavity; the brain was evidently injured; and the part looked just like an ulcer in a mucous membrane. I presume that, in this cavity, blood was effused; it coagulated, and was then partly absorbed. It produced a destruction of the cerebral substance around it; and the blood, being partly absorbed, gave rise to the dark colour. I have always seen the injury on the opposite side to that on which the paralysis occurred.

*Occasional Presence of Inflammation.*—Sometimes, besides congestion and effusion, we find marks of more or less inflammation. The membranes are thicker than they should be;—looking as if chronic inflammation had been going on. In the man just referred to, the arachnoid on the surface of the brain was quite opaque; and there was also a considerable effusion of serum; but then he died from an inflammatory attack of the brain. His head suddenly became very hot; he became stupid; and then effusion took place into the substance of the brain, and likewise into the ventricles. This was a subsequent process; and is a very common mode in which paralytic persons die. There is a disposition to disease. In most chronic diseases effusion takes place; and, there being no strength of constitution, the patients die. They sink from inflammation within.

*Diseased State of the Vessels.*—This laceration,—this rupture of the vessels with effusion of blood, very generally takes place from some disease of the vessels themselves. Now and then, the vessels within the head have been found aneurismal. Very frequently, too, they are found more or less ossified. Sometimes they become calcareous;—more or less earthy, and very brittle. It is said that even the veins outside the head, are occasionally found diseased in a similar way. The vessels are so brittle that they will crack; and apoplexy takes place.

*Small Vessels usually Ruptured.*—Now and then, a very large vessel in the head has been found ruptured;—even a large artery. Generally, however, it is the *small* vessels that suffer; but even the sinuses have been found in that state. An instance of the lateral sinus being ruptured, is mentioned in the “*Journal Universel*” for 1820. There is another instance mentioned in the same work, of the lateral sinus being ruptured, in a person intoxicated. In the “*Edinburgh Essays and Observations*,”<sup>a</sup> there is another instance mentioned, where the lateral sinus was ruptured, and apoplexy was the consequence. A practitioner informed me, that he was once sent for to a man, who had been carrying a very heavy load; and he found the longitudinal sinus ruptured. We must suppose there was a disposition, general or local, to disease of some kind. Usually, it is the small vessels that give way; and next to them come the arteries. The sinuses are certainly more rarely affected than either.

*Hæmorrhage External to the Skull.*—The hæmorrhage, it is said, is sometimes found outside the skull; so that, on removing the skin, the hæmorrhage has been seen there. This is by no means uncommon after external violence; but, when it does not arise from that source, it happens from a bone being carious, and a vessel of the “*dura mater*” thus becoming injured.

*Effusion of a Urinous Character following Ischuria.*—It is said that, in cases where apoplexy follows the suppression of urine, a great quantity of fluid has

<sup>a</sup> Volume 5; Part 2; Page 106. (Fifth Edition.)

been found in the brain; and even fluid of a urinous character. Whether that is true, I will not take upon me to say; but some people have even found gin in the brain;—at least so it is said. It is stated that an old woman, who had been much addicted to drinking gin, died at the Westminster Hospital. She died with her stomach full of it; and there was a distinct smell of gin in the ventricles of the brain. It is also said, that tincture of assafœtida<sup>a</sup> has found its way to the ventricles; or that there has been a strong smell of it in persons who have died apoplectic. An effusion has taken place into the ventricles of persons previously taking assafœtida; and it is said that there has been a strong smell of it in the brain. These things *may be*, and I suppose *have been*; but I have not seen them. Certainly, when persons have been unable to make water, and the urine has been retained, there can be no doubt that they have occasionally vomited urinous fluid, and even expectorated a fluid strongly smelling of urine. If this be the case, it is possible that such an occurrence may take place in the ventricles of the brain; but I can only say that I never saw more than one instance of apoplexy from ischuria, and in that case there was no effusion (of any kind) into the brain.

### SECTION III.—CAUSES.

#### *a. Predisposing Causes.*

*Hereditary and Constitutional.*—The predisposition to this disease may be constitutional, or even hereditary;—an hereditary make of the head, neck, and body at large. Men who have a large thick head, are those that are usually affected; because that is not the shape for intellect. It is a *long-headed* man that is generally thought clever. Men with short necks, circular breasts, and not very tall, are certainly very liable to apoplexy. This is, of course, a constitutional make; and if it happen to be hereditary also, the predisposition to apoplexy may be said to be hereditary, as well as constitutional.

*Indolence and Excess of Food.*—In the next place, indolence of body and mind will predispose to it. Persons who satisfy themselves with little exercise, and little mental exertion, have more or less congestion; and at last become apoplectic. If persons sleep too much, they become more or less plethoric, and liable to become apoplectic. Food too rich and too abundant, will have the same effect. It is said that Boerhaave had a student, who took it into his head that sleep was the natural state; and he slept as hard as he could; till at last, from the want of external excitement, he fell into apoplexy.

*Hypertrophy of the Brain.*—Hypertrophy of the brain tends to produce this disease;—an occurrence which we might *à priori* expect. Over-nourishment of the brain is likely to dispose to congestion, and to irregularity of the circulation. I once saw an instance of this kind; and only once. It occurred in a young gentleman, eleven years of age, who had a head bigger than most men;—in fact, it was too large for his body. He was remarkably clever, and was not contented with the society of other children, but associated with his father and mother. He studied many things; but more particularly political economy. He was seized one day with hemiplegia, and had double vision; and the attack was soon followed by coma. Previously he had had double vision, and pain of the opposite side to that in which hæmorrhage afterwards took place. After death, the only thing I could discover was congestion in the brain; and I fancied that the “*corpus callosum*” was softened. A few minute tubercles were found in the arachnoid; but nothing to cause apoplexy. His brain was far larger than it ought to have been in a child of his age; indeed, the brains of very few adults attain so large a size. In the “*Dictionnaire des Sciences Medicales*” (under the article “*Rare Cases*”), there is mentioned the case of a German, who died apoplectic at the age of thirty.

<sup>a</sup> From “asa” (Hebrew), *to heal*.

He had very powerful mental faculties. His head began to grow at seven years of age; and at thirty it was twenty-seven inches five lines in circumference. The rest of his body was not proportionate; and, like my patient, he died apoplectic.

*Decline of Life.*—Apoplexy is also predisposed to by the decline of life. Of those persons who die apoplectic, more than half have passed the meridian of life; with the exception of children, who die in consequence of effusion. Apoplexy occurs in children, every day, from an inflammatory state of the head, which causes more or less effusion; but apoplexy from congestion of blood, and effusion through diseased vessels, more frequently takes place after the middle period of life.

*Cessation of Discharges.*—It occasionally takes place from the sudden cessation of a discharge;—from the cessation of the menses, or from amenorrhœa; but not so frequently as might be imagined. The most we generally see, when women do not menstruate regularly, is headache and giddiness. The suppression of hæmorrhoidal discharge has produced apoplexy; and the cessation of a long-continued cutaneous eruption, will do the same; and likewise metastasis, on the cessation of gout; and even, it is said, the removal of tumours.

*Organic Disease of the Head.*—Apoplexy is strongly predisposed to, by organic disease in the head;—in the brain, or in the membranes, or on the inner table of the bones, or in the whole substance of the bones. When there is organic disease outside the brain,—whether of the bones, or the pericranium, or the inner tables, or the “dura mater,”—then a person, from the excitement going on there, is very much disposed to this disease.

*Anxiety.*—Anxiety of mind has a tendency to produce it. When persons are very anxious, they soon experience heaviness of the forehead; and apoplexy is soon induced.

*Manner in which these Causes Act.*—Many of these things act by merely giving rise to excessive fulness; and if there happen to be, in the individual who is exposed to these predisposing causes, any organic disease of the vessels or membranes of the brain, it is easy to perceive how easily the excessive load of blood there, may occasion apoplexy. When there is organic disease of the vessels, of course, it does not require a full habit, full living, a short head, and a thick neck, to induce the disease. If any of the vessels be diseased, though a person may be as thin as a lamp-post, and nearly as tall, he will be liable to apoplexy; and people wonder that a person so spare, should die of such a disease. It is so frequently the result of blood being effused through the state of the vessels, that we must expect to see this disease in thin people;—not so often as in fat persons, certainly; but very frequently. It may arise without any fulness of the vessels whatever; but simply from one vessel, or a set of vessels, being brittle, or softened, or ulcerated, or labouring under some other disease; and it will arise from mere fulness of all the vessels;—the vessels themselves being sound, but suffering more or less congestion. We may therefore expect apoplexy in two very opposite descriptions of people; and when it arises from the state of the vessels, none of these other predisposing causes are required. A person may live the most abstemious life possible; and yet the vessels may let out the blood, and the person die apoplectic;—so that no exciting cause may be required for it: nor any of those predisposing causes which I have mentioned, as operating by occasional fulness of the head.

### b. *Exciting Causes.*

*Stooping.*—As to the exciting causes of the disease, they may be equally influential in producing it, whether there is mere fulness, or organic disease of the vessels. Stooping, especially if a person make an effort while doing so, is a common cause of apoplexy. If there be previously great congestion of blood, even without disease of the vessels, stooping will increase it to such a degree, that apoplexy may occur. Supposing there is brittleness of the vessels, stooping will have the same effect as if there were great congestion. So that a common exciting cause of the disease, for the most part, will produce apoplexy, whether it arises

simply from an over-fulness, or from disease of the vessels; because stooping, for example, is a violent effort, which will throw a great quantity of blood on the head; and will operate by forcing the blood through, or opening the vessels.

*Heat and Cold.*—Exposure to a very great fire, or being in a very close apartment, are causes of the disease; and so likewise are the rays of the sun;—insolation. Cold causes stupor. When persons are exposed to intense cold, they become exceedingly heavy;—they are disposed to sleep; and it requires a strong exertion on their part, to prevent them from going to sleep. When they travel over regions of snow, and have nearly perished from cold, if they give way to sleep, and lie down, they are sure to die. Yet they will be careless; and, though their friends tell them of their danger, and entreat them not to lie down, the propensity to sleep is so great, that they cannot resist it; and the cold at last produces apoplexy. When a person falls into a sound sleep, I believe that death from cold is by no means unpleasant. Of course, it is unpleasant to be killed; but when persons are benumbed, they lie down quietly, in an apoplectic state. It is said by Portal, a French physician, that he found a rupture of a vessel in a person who had died in this state. It would appear others had observed, that cold killed merely by numbness;—taking away all excitement from every part of the body, and the brain among the rest. The late Dr. Kellie, in the first volume of the “Edinburgh Medico-Chirurgical Transactions,”<sup>a</sup> says that he found serous effusion, and great congestion of the head, in two persons who were destroyed by cold.

*Tight Bandages on the Neck.*—Tight bandages round the neck, have frequently produced apoplexy, or threatened to do so;—that is, the person would have had it if they had not been loosed. It might be supposed that the tight bandage which is applied by Jack Ketch, would occasion this disease; and Sir Benjamin Brodie says that, in a person who was hanged, he saw effusion of blood. Dr. Munro, likewise, says that he found, in two cases, congestion of the scalp, and congestion within the head. But this is not always the case. Persons who are hung, do not die of apoplexy; but of a want of breath. Occasionally it has happened that apoplexy has been produced;—for Sir Benjamin Brodie (on whom we may place implicit reliance) has found not only extreme congestion, but even rupture.

*Drowning.*—Sometimes, great cerebral congestion has been found, after drowning; but there are several authors who deny the truth of this statement. Drs. Good, Winslow, and Currie, say that, after drowning, no congestion was found. Morgagni says that, after hanging, he found no congestion. De Haen says that, after hanging and drowning, nothing was to be found; and so says Dr. Kellie. It appears, therefore, that a person may be hanged or drowned, and no congestion or rupture take place; but, in other cases, there may be rupture. People, from drowning, hanging, suffocation, and cold, do not die necessarily of apoplexy. There *may* be apoplexy in addition; but not necessarily so. I presume that a great deal will depend on the strength of the vessels. If the vessels be very strong, they will not give way;—they will not allow great congestion to take place; but if, on the other hand, they be weak, they will allow it; or, if they be diseased, they will allow the blood to be effused.

*Narcotics and Intoxication.*—Narcotics will give rise to this disease. They produce various disturbances of the brain;—sometimes delirium, sometimes more or less phrenitis, and sometimes apoplexy. They cause apoplexy, by inducing compression, where there is great congestion of the head; but, independently of producing this compression of the vessels, they do harm by their peculiar narcotic power;—by destroying the vital powers of the body; just as cold will produce death, independently of congestion. Intoxication, too, will frequently produce the same effect.

*Other Exciting Causes.*—Among the exciting causes of the disease, we find mentioned “lying on a millstone;” but I do not suppose that any one lies down

in such a situation. If it do produce death, it is by the centrifugal force driving all the blood to the head; so that apoplexy is induced.

Anger has sometimes destroyed life by apoplexy. Ischuria renalis has been also found to produce apoplexy.

*Inflammation.*—Inflammation and suppuration of the brain frequently produce apoplexy. The inflammation goes on to such a pitch, that apoplexy at last ensues from the congestion. Suppuration within the brain causes such a collection of pus, as to compress it; and the compression may produce apoplexy.

*Depressed Bone.*—The pressure occasioned by a depressed bone, likewise gives rise to apoplexy. After an injury inflicted on the head, persons are frequently brought to the hospital perfectly comatose,—in a state of apoplexy; and, when the bone is raised, they recover.

*Is the Brain Compressible?*—Some, however, deny that pressure will produce these effects;—at least, they deny that the brain is ever compressed. They say that the cavity of the cranium must always be full;—that if the veins be compressed, so that the blood cannot escape, so much less blood goes up to the arteries; or that, if we quicken the pulse, and increase the usual quantity of blood in the arteries, the veins contain proportionately less. Dr. Kellie, who takes this side of the question, says that he bled animals to death; and that he still found a great quantity of blood in the head;—so that the cavity must be filled. If we press more in one way, more comes out the other; or, if we endeavour to withdraw the blood, we cannot; because the cavity must be filled, and therefore we can only take away a certain portion.

All this may be true; but yet I should think there may be more blood in the head at one time, than at another. The cranium may be full; but I should think there may be different degrees of packing. A portmanteau may be filled; but it may be packed tightly, or packed loosely; and when we see that, if a person stoops, he becomes stupid and sleepy and giddy; and that all the vessels of the external part of the head are distended with blood; and when he suffers what, in a higher degree, would be apoplexy;—I cannot help thinking, that there is more blood in the head at one time, than at another. I should conceive that the cerebral substance may be pressed in a different degree. There must be a certain quantity of blood in the brain, resisting the entrance of more; but I should think that more might be *forced* upon the brain;—so as to compress the cerebral substance, and bring it into a smaller bulk.

When the face is red and full, all the external veins turgid, and the person is labouring under evident external plethora of the head, while (at the same time) he has signs of apoplexy, after death, all the internal vessels of the head are almost sure to be found in a state of congestion; and hence, to all appearance, there is far more blood in the head at one time than at another. If a person tie his cravat tightly, he instantly has the external veins of his face filled; his eyes become red; he feels, at the same time, stupid and giddy; and if he do not loosen it soon, he is very likely to drop down. Some have denied that there can be congestion of blood in the head, from this circumstance; that, after hanging and drowning, there has frequently no apoplexy been observed;—no congestion of blood, and no effusion; but, I presume, this will all depend on the strength of the vessels, or on the vessels not being diseased. If they be in this healthy condition, I presume they will resist an overload of blood, and not give way;—that they will not allow either rupture, or congestion of blood. It is well known that persons with hypertrophy of the left ventricle of the heart, frequently become apoplectic;—there being such a quantity of blood forced violently towards the brain. But it is said, that we every day see a quantity of blood violently driven up to the head; and yet no apoplexy is produced. I presume the reason is, that the vessels are so strong, that they will not become over-distended;—they will not give way; whereas, in other persons, they are diseased or feeble, and *do* give way; so that congestion is produced. I cannot see the force of the argument that has been adduced. I will not deny, that there may be only a certain quantity of blood in the head; but I

do think that the cerebral substance may be more compressed at one time than at another;—that the contents of the cranium may be packed more closely.

*Will Pressure cause Apoplexy?*—Some contend, however, that we are able to say nothing about the existence of pressure; or, allowing that pressure does take place, they deny that it will produce apoplexy. Serres asserts, that actual compression does not produce apoplexy. He trephined several dogs, and then wounded the brain through the aperture,—so as to produce effusion of blood; and yet, he says, apoplexy did not occur. Whether we can depend upon his statements or not, I will not pretend to say; because some say we cannot. But if we can, I presume the reason there was no apoplexy was simply this; that if an opening were made in the cranium, the pressure would be *without* and not *within*; because the opening would allow the contents of the skull to be pushed forward. But, he says, after he had cut a piece of bone, he closed the opening with a cork, so as to press on the brain; and no apoplexy was produced. This, however, appears to me questionable. That the brain will bear pressure, without much effect being produced,—provided it take place gradually,—is proved by Dr. Heberden's case of gradual compression; which I mentioned while describing chronic hydrocephalus.\* Sudden pressure caused by a less quantity would, I presume, have produced apoplexy. Dr. Marshall, formerly a lecturer and anatomist in London, mentions the case of a maniac who, a few hours before death, had become rational; and he found rather more than a pint of serum in and upon the brain;—showing what may be borne, if the part be accustomed to it gradually.

*Tumours within the Head.*—When there is any tumour within the head, it will act (I presume) not merely by being a source of occasional irritation, but by occupying so much space in the cranium, that the least additional presence of blood upon the brain is likely to produce effects, which would not be produced if the tumour were not there. If the capacity of the cranium, for example, be at all diminished by the presence of a foreign body, of course it can less easily bear any additional quantity of blood which may be forced up; and therefore tumours may act in two ways;—first, by exciting a sudden determination of blood to the head; and, secondly, by filling up the cavity of the cranium so much, that even a little additional flow of blood cannot be borne;—there is no room for it. We sometimes see cases of persons, who have died with a tumour within the head; which produced only occasional paralysis, or occasional loss of motion;—a kind of stupor. In such a case it might be said, there was no organic disease; because the symptoms were only occasional. That I know has occurred; and, I presume, from this circumstance;—that the tumour has gradually accustomed the part to its presence; and when apoplexy and paralysis have occurred, (as they have from time to time,) it has not been from the tumour being there; but from an additional flow of blood, which could not be borne. Thus the tumour itself was not the cause of the occasional fits of apoplexy; but it was the additional congestion of blood, which could not be borne, in consequence of the presence of the tumour, or something occupying the cavity of the cranium. For it is a fact, that we sometimes see persons with considerable pressure; but as it came on slowly, the apoplexy, or paralysis, has only been occasional;—has occurred only when an additional quantity of blood has been forced to the head; which could not be borne, on account of the narrowed dimensions of the cranial cavity.

#### SECTION IV.—TREATMENT.

In this, as in every other instance of disease, if there be an evident exciting cause still in existence, and removeable, we should remove it.

*In Cases of Depression.*—Supposing it to arise from the depression of a piece

of bone, that is a surgical case; and no medicine in the world can remove the symptoms, while the bone remains in that position. In all probability, it would be a proper practice to attempt the elevation of the bone. The pulse has sometimes been quite imperceptible, while the bone was depressing the brain; but immediately on the bone being elevated, it has become strong. Sir Benjamin Brodie mentions such a case.<sup>a</sup> He says the pulse was only 40, while the bone was pressing on the brain; but on its elevation, it instantly rose to 60.

*Intoxication.*—If we know that the apoplexy has arisen from any thing taken into the stomach, we should adopt proper steps to evacuate that organ;—that is to say, emetics, or mechanical means (the stomach-pump).

*Treatment in ordinary cases.*—If it be an ordinary case of apoplexy, however, the first thing to be done is to raise the person's head and shoulders, to loosen every thing about his neck, and to open a vein in the arm, or the jugular vein. As to the quantity of blood to be withdrawn, I need not say any thing; for that must depend on numerous circumstances.<sup>b</sup> The next thing should be to give a full dose of purgative medicine;—a drop or two of croton-oil, or a scruple of calomel. Perhaps it would be well to give a dose of calomel, whether alone or in combination; because early ptialism, after apoplexy, often appears useful. There is effusion left, for which ptialism is apparently useful; and it is well to lay the foundation for it, by beginning with calomel as a purgative. As it is best to open the bowels very speedily, a strong purgative injection should next be given. The state of the brain causes the heart to be more or less torpid, and likewise the alimentary canal;—giving rise to a slow pulse, and torpidity of the bowels; and a clyster of oil of turpentine (two or three ounces) answers very well. Whether it is objectionable on account of stimulating the brain, and producing vertigo, I do not know; but I am not aware that I ever saw harm arise from it. A good clyster is one of the best things;—sulphate of magnesia or an infusion of the extract of colocynth, answers very well. It is made in a moment; and may be exhibited in gruel, or barley water. It is very useful to apply water to the head;—much more so than a blister. The head generally is hot; and ice, applied in a bladder, is exceedingly serviceable. The patient should be kept very low; and sinapisms, applied to the feet or legs, may be useful. But the great point is to raise the person; to keep him as upright as possible; to loosen every thing about the neck; to bleed freely; to give an active purgative; and instantly, without waiting for the operation of this purgative, to introduce a strong acrid injection into the rectum, and to apply ice to the head. It would be well, afterwards, to continue the calomel till the mouth is tender; and that on two accounts. First, the head is frequently hot in this disease;—it is so often an inflammatory disease; secondly, we frequently find the blood buffed and cupped;<sup>c</sup> and I may say, in the third place, we often find paralysis occurring; and that appears to be the result of effusion, the excess of which should be absorbed. Calomel may be useful in that respect.

<sup>a</sup> "Medico-Chirurgical Transactions;" Volume 14; Pages 355 and 356.

<sup>b</sup> Dr. Marshall Hall has drawn attention to an important difference in the treatment of mere *congestion* and of actual *rupture*.—"In the former there is extreme tolerance of loss of blood; in the latter, the system is extremely, and even dangerously, susceptible of this loss." He, therefore, attaches importance to "placing the patient in the perfectly upright posture, before the blood is allowed to flow: we must watch his countenance, and his breathing; keep our finger on his pulse; and, the moment the slightest indication of approaching syncope takes place, arrest the flow of blood, and place the patient recumbent." ("Principles and Practice of Medicine;" Page 256; Section 1177.)

<sup>c</sup> According to Dr. Milne Edwards, ("Cyclopædia of Anatomy and Physiology;" Volume 1; Page 414,) the buffy coat may appear in plethoric persons, without the existence of inflammation. The same author also quotes the experiments performed by M. Ratier, to prove that various circumstances, altogether independent of the physiological state of the individual, may also exert a great influence on the formation of the buffy coat. Dr. Babington (in the same work, Page 420) states that the buffy coat may even be absent in the most intense inflammation; for the circulation may be so overcharged (either actually or relatively), or the nervous power so oppressed, that the requisite degree of propulsive force is not exerted by the heart and arteries; nor the vital energy, on which slow coagulation depends, imparted to the blood.

*Necessity of Caution in the Treatment.*—Great care, however, must be taken not to carry this too far; for there can be no question that persons will sink after a time, entirely from these measures being pushed beyond their proper extent. Although we starve the patient the first few days, we must ultimately give him support. I am sure that some persons have had apoplexy, from having been bled too frequently, even locally; and from having been deprived too long of food. It is all very well in the first instance; but if the patient begin to sink, we should not continue to evacuate. It is necessary to get the mouth sore, and then to apply a blister behind the ears, and over the head; and after a time, if we please, over the whole of the head; but great care must be taken not to evacuate too much.

*Serous and Sanguineous Apoplexy.*—There was formerly a distinction drawn between *serous* and *sanguineous* apoplexy;—"serous," where it arose from effused serum; and "sanguineous," where there was great congestion of the vessels, or rupture. Taking this distinction literally, it is altogether absurd; as will immediately appear, when we consider the indications of cure. It was supposed, than when there was *sanguineous* apoplexy, we were to bleed, purge, and starve; and when it was *serous*, we were to support the patient well;—because it was a case of apoplexy from the oozing of water. That was absurd; because we may have serum where the inflammation is more or less severe;—in a case where it is quite proper to bleed, purge, starve, and apply cold. Common inflammation of the arachnoid membrane, whether it be active or not, will produce it; and, in the next place, where we have effusion of serum, there is often great congestion of blood. We may have it in both cases; and nothing is more common, when a vessel is ruptured in the head, than to find serum effused upon the brain, and outside the head. Serum, in this case,—as in its effusion in all other parts of the body,—may be the result either of weakness, of congestion, or of inflammation; and therefore we see, that no treatment of apoplexy can be founded on the presence or absence of serum, even could we tell it beforehand; any more than an indication of practice can be drawn from serum in other parts. Serum may be effused in *peritonitis*; and yet we may have to treat the case as *active* peritonitis; or we may have to support the patient well, and to give stimuli; and the same remark applies to the brain. Hence this distinction is not founded on pathological principles. Where a person appears plethoric, we must treat him by depletion; but where he looks pale, watery, leucophlegmatic,<sup>a</sup> and has a weak pulse, (as if the effusion were serum,) then we should not employ active depleting measures, but be exceedingly careful; and perhaps we may have to support him. There is a distinction to be drawn; not because there is serum or no serum; but because in the one case there is a state of fulness and congestion, and in the other a state of debility. It is necessary to consider the powers of the patient. In some of these cases, the patient looks as though he would be dropsical in the head; and every other part of the body is pale and white; and if an effusion of serum took place, it would be more from weakness than any thing else; yet in such persons as these, after death, we continually find congestion, and more or less organic disease, giving rise to the effusion of serum. We must depend on the state at large, and proceed on general principles, and not as to whether there may be serum or not; for we cannot tell its presence *à priori*.

*After-Treatment.*—After the fit is over, and the patient has recovered, it is necessary to pursue the general treatment which was adopted during the fit; only on a more moderate scale. If it be necessary to bleed copiously, to treat the case very antiphlogistically (or in a very depleting mode), of course the patient should be very abstemious in his diet, should keep an open state of his bowels, and use (though in great moderation) all those measures which are calculated to prevent a phlogistic condition from occurring. If a patient have not borne an evacuation during the disease, of course a more generous diet must be allowed;—we need not be so strict. Dr. Babington, from his own extensive experience, became convinced

<sup>a</sup> From λευκος, *white*; and φλεγμα, *phlegm*.

that many persons were made to suffer exceedingly, from having antiphlogistic measures carried too far; not only from the very outset, but afterwards. He says that he found great advantage, after a time, from the moderate exhibition of tonics.

*Apoplexy from Ischuria.*—There is one kind of apoplexy in which it is necessary to give a particular remedy, or we shall be sure to lose our patient; and that is apoplexy arising from the suppression of urine. I believe, in that species of the affection, evacuants do little or no good; but that cantharides, employed both internally and externally, are the proper remedy. It is well to resort to them always; and to give a grain two or three times a day. I should not recommend the tincture; for I believe it is uncertain in its operation. I have given two or three drachms, two or three times a day, without any effect; and sometimes I have given the same quantity, and found great irritation. I do not think there is a more uncertain medicine in the Pharmacopœia, than tincture of cantharides; nor do I think there is a more certain one than the powder. One or two grains, given every night, or night and morning, will be almost sure to make the bladder perform its functions. The only experience I have had of cantharides internally, has been in cases of gleet; but it has been unsatisfactory, on account of the people to whom it was administered being out-door patients;—so that I had no great control over them; and therefore I cannot speak as to its powers. I have no experience of it in apoplexy from ischnria. I applied it in one case; but the patient died in twelve hours;—so that there was no time for it to do him good. But a gentleman told me, that he had seen it successfully exhibited in two cases. In the first case, Sir Astley Cooper suggested its employment; and, although an unfavourable prognosis had been given, the patient recovered. The second case, shortly afterwards, fell under the same gentleman's care; and he adopted the same remedy with equal success. It does appear that, in this kind of apoplexy, stimulation of the urinary organs is the proper remedy.

*Increase of Apoplexy.*—It is said, that apoplexy and palsy have very much increased of late years. Dr. William Heberden, the son of the author of the "Commentaries," has written a very excellent paper, upon the increase and decrease of different diseases; and he states, that the increase of apoplexy and palsy has, of late, been gradual and constant.<sup>a</sup> His paper was written about forty years ago.<sup>b</sup> Whether people drink more porter and strong malt-liquors now than formerly, I do not know. The upper orders drink less wine; but the lower orders may drink more porter. I do not know how it is to be explained; but there are double the cases now, in proportion to the population, that there were a hundred years ago. Sir Gilbert Blane mentions, that he had more apoplexy in the hospital, than in private practice; and the people who go there certainly drink more porter, than their superiors in society. I suppose porter or spirits, or both, have more tendency to produce the disease, than wine. If it were the wine which produced the disease, as that is now so much less drunk than formerly, the proportion of cases would not be what Dr. Heberden has stated.

<sup>a</sup> "On the Increase and Decrease of different Diseases, particularly of the Plague."

<sup>b</sup> In the year 1801.

## CHAPTER IV.

## CEREBRAL AFFECTIONS FROM REMOTE CAUSES.

INDEPENDENTLY of inflammation and congestion, a highly important series of morbid phenomena may arise; presenting many points of resemblance to cerebral inflammation and apoplexy; and resulting from peculiar affections of the general system, or of various organs. The causes of these affections may be reduced to the following heads:—1. Intestinal irritation. 2. Exhaustion from loss of blood. 3. Excessive study; shock; alcohol. 4. Chlorosis; dropsy; ischuria.

## SECTION I.—CEREBRAL SYMPTOMS FROM INTESTINAL IRRITATION.

[The first of these affections consists of irritation from indigestible food, scybala, or other morbid contents of the stomach, or bowels; excited into activity by some *shock* of the system, or of the nervous system;—such as a fall or other accident, parturition, &c.]

*Symptoms.*—The symptoms are, rigor, frequently severe heat of surface, and violent pain of the head, with intolerance of light and sound; symptoms, in a word, of the most acute encephalitis. The breath is tainted, the tongue loaded and swollen, and the secretions are morbid; but it would still be difficult to establish a distinct and confident diagnosis without the criterion afforded by the effect of blood-letting in the erect posture.

*Diagnosis and Treatment.*—The first step to be taken, in a doubtful case, is very slowly to administer an enema, of from three to three and a half pints of warm water; and to examine the state of the fæces, and observe the effect upon the disease, and upon the system. If there be scybala, if the symptoms be subdued, and especially if there be faintishness, the case is, indubitably, not cerebral inflammation, but intestinal irritation. If the case still remain doubtful, we must prepare the arm, open a vein, and then place the patient upright, and let the blood flow until the lips become pallid; if the case be encephalitis, an extreme quantity of blood will flow,—even thirty or forty ounces or more,—before there is any appearance of syncope; if it be intestinal irritation, syncope occurs before one fourth of that quantity of blood has left the circulating system. The importance of this distinction is immense; for the injudicious use of the lancet has, in too many instances, led to the most serious and even fatal consequences.

This affection sometimes assumes a far less acute form. I<sup>a</sup> recently met with such a case, which had been mistaken for encephalitis. The patient slowly but perfectly recovered from attacks of vertigo, &c., by maintaining a regular state of the bowels, by diet, and rest; and afterwards by gentle exercise, change of air, &c.<sup>b</sup>]

## SECTION II.—CEREBRAL SYMPTOMS FROM EXHAUSTION.

*Causes of Exhaustion.*—[Exhaustion, in early infancy, has its origin (chiefly) in diarrhœa, or catharsis; in the later periods of infancy, in the loss of blood, with or without a relaxed or evacuated condition of the bowels. The state of diarrhœa

<sup>a</sup> Dr. Marshall Hall.

<sup>b</sup> "Diseases and Derangement of the Nervous System; by Marshall Hall, M. D." Page 351.

has generally depended upon improper food, or intestinal irritation. It has very frequently succeeded to weaning, or to other changes in the diet, or to constipation. The catharsis<sup>a</sup> has followed the administration of an aperient medicine; which, at such a moment of disorder of the stomach and bowels, is likely to act excessively. The exhaustion from loss of blood generally follows the inappropriate or undue application of leeches, or the use of the lancet.

In the adult, exhaustion chiefly arises from loss of blood; but it may have its origin in undue lactation, leucorrhœa, &c. If the more immediate effects of exhaustion be well known, the more remote have been overlooked, or mistaken for other morbid affections. Yet, to the physician, the symptoms of reaction from loss of blood,—so similar to those of some affections of the head, and of the heart, present subjects for his observation of the utmost moment in actual practice. The diagnosis of these cases is most important; for the prognosis and treatment alike depend upon it.

The remote effects of exhaustion, are particularly apt—from their similarity to inflammatory diseases, and from the present though transient relief afforded by the further detraction of blood—to deceive the unwary. They consist in:—1. Sickness and vomiting. 2. Excessive reaction; sometimes accompanied with delirium, mania, coma, amaurosis, or deafness. 3. The sinking state. Of these, the two last claim our special attention.

*Excessive Reaction.*—Excessive reaction is formed gradually; and consists, at first, in forcible beating of the pulse, of the carotids, and of the heart; and eventually, perhaps, of beating or throbbing in the scrobiculus cordis, and in the course of the aorta. This state of reaction is augmented, occasionally, by a turbulent dream, mental agitation, or bodily exertion. At other times, it is modified by a temporary faintness or syncope. There is also sometimes irregularity of the heart, and of the pulse. The respiration is apt to be frequent and hurried, and attended with alternate panting and sighing; the movement of expiration is sometimes obviously and singularly blended with a movement communicated by the beat of the heart; the patient requires the smelling-bottle, the fan, and the fresh air. The skin is sometimes hot; and there are frequently general hurry and restlessness. In this state of exhaustion, sudden dissolution has sometimes been the immediate consequence of muscular effort on the part of the patient, or of his being too suddenly raised from the recumbent into the erect position.

*Its Resemblance to Arachnitis.*—In the more exquisite cases of excessive reaction, the symptoms are still more strongly marked, and demand a fuller description. Sometimes it resembles arachnitis. In those cases, the beating of the temples is at length accompanied by a throbbing pain of the head, and the energies and sensibilities of the brain are morbidly augmented. Sometimes there is intolerance of light; but still more frequently intolerance of noise, and of disturbance of any kind; requiring stillness to be enjoined, the knocker to be tied, and straw to be strewed along the pavement. The sleep is agitated and disturbed by fearful dreams; and the patient is liable to awake, or be awoke, in a state of great hurry of mind, sometimes almost approaching to delirium. Sometimes there is slight delirium, and occasionally even continued delirium; more frequently there are great noises in the head;—as of singing, of crackers, of a storm, or of a cataract. In some instances there are flashes of light; sometimes there is a sense of great pressure or tightness in one part of the head, or round it;—as if the skull were pressed by an iron nail, or bound by an iron hoop.

*The Sinking State.*—This is adopted, not to express a state of negative weakness merely,—which may continue long, and end in ultimate recovery,—but to denote a state of positive and progressive failure of the vital powers; attended by its peculiar effects, and by a set of phenomena very different from those of exhaustion with reaction.

If in reaction the energies of the system are augmented, in sinking the functions

<sup>a</sup> From καθάρσις, to purge.

of the brain, as also of the lungs and heart, are singularly affected. The patient is no longer affected by noises as before; there is, on the contrary, a tendency to dozing; and gradually some of those effects on the muscular system which denote diminished energy of the brain supervene; as snoring, stertor, blowing up of the cheeks in breathing, &c. Instead of the hurry and alarm on awaking, observed in cases of excessive reaction, the patient, in the state of sinking, requires a moment to recollect himself, and recover his consciousness. He is perhaps affected with slight delirium, and is apt to forget the circumstances of his situation; and, inattentive to the objects around him, to fall again into a state of dozing.<sup>a]</sup>

#### a. *Spurious Hydrocephalus.*

*History.*—It is very necessary to know, that symptoms like those of acute hydrocephalus, or many of them, may occur in a state of the system, where the loss of blood, or even purging and starvation, would be fatal. I believe we are indebted for our knowledge of this state, to Dr. Marshall Hall. It was imagined (and I myself fell into the error) that Dr. Gooch was the first person who described it; but Dr. Marshall Hall wrote to me on the subject; and it appeared, on referring to his book, that the priority of discovery was due to him; and that Dr. Gooch was himself indebted to Dr. Hall for a knowledge of the fact. It is a condition of which I was not aware when I began to practise; but it is of the highest importance to be acquainted with it; because inappropriate treatment will, to a certainty, destroy life.

*Symptoms.*—It now and then happens, that a child becomes exceedingly drowsy, has dilatation of the pupils, perhaps squints, and may likewise experience more or less delirium;—so as to appear to be labouring under hydrocephalus. But usually, in such a state, there is no pain of the head, or it is only transient; and the skin is cool, or absolutely cold. The pulse (as in hydrocephalus, and other inflammatory diseases) is quick; but it is weak; and the face is not flushed as it is in inflammatory diseases; but it is perhaps pale, or flushed only transiently. In this state, if we apply leeches, or if we purge, in all probability the patient will sink. This state will sometimes happen from the first. A child, perhaps after diarrhœa, —after something which has weakened him very much, falls into a state of torpor of the brain. It becomes very heavy, stupid, and half blind. The pupils are dilated, and there is perhaps even squinting; but I do not know that the latter is common. This set of symptoms will come on, at the end of the inflammatory stage of hydrocephalus, and sometimes it is the result, as I just now remarked, of some previous disease.

*Diagnosis.*—[The condition of the cheeks, with regard to colour and warmth, may be considered as the *pulse* of very young infants;—indicating the degree of remaining power, or of exhaustion. In the present case, especially, there is no symptom so important,—so distinctive. It is from the condition of the cheeks, in conjunction with a due consideration of the *history*, that the diagnosis of this morbid state, and the indication of the appropriate remedies, are chiefly to be deduced. The general surface, and especially the hands and feet, also afford important sources of information, as to the condition of the nervous or vital powers. Next to these, the degree of frequency of the pulse, and the character of the breathing, are points of the greatest importance. During the stage of irritability, the breathing is quick; during that of torpor, it is slower, irregular, suspirious, and (finally) crepitous. The pulse changes in its beat;—from being full, becoming smaller; but retaining, perhaps, its former frequency. We should be especially on our guard, not to mistake the stupor, or coma, into which the state of irritability is apt to subside, for natural sleep, and for an indication of returning health. The pallor and coldness of the cheeks, the half-closed eyelid, and the irregular breathing will sufficiently distinguish the two cases.<sup>b]</sup>

<sup>a</sup> "Principles of Medicine; by Marshall Hall, M. D." Part I; Chapter 7.

<sup>b</sup> "Diseases of the Nervous System; by Marshall Hall, M. D." 1841. Paragraphs 742 and 743.

*Morbid Appearances.*—When children have died in this state, frequently nothing morbid has been found in the head; or the vessels of the brain have merely been found unusually serous. There may be a little effusion; but, in many instances, the vessels have been less distended with blood than usual.

*Treatment.*—When a child is in this condition, it is best to give it beef-tea and ammonia every three or four hours. The rapidity with which improvement takes place, is very great.

In most inflammatory diseases, a stage may come on, in which perseverance in the antiphlogistic plan is highly improper. A state of irritation comes on, in the stead of inflammation; and the treatment appropriate to the one, is most inappropriate to the other. I was recently sent for to a person who had evidently laboured under phrenitis. He had been bled, purged, and so on; but the time had arrived for discontinuing antiphlogistic treatment, and adopting the opposite plan. His pulse was 120, and feeble; there was no flushing of the face, and no redness of the eyes; but there was delirium and feebleness of pulse;—indicating that no more evacuations were necessary. So far from that, we agreed to give him a full dose of opium. He took four grains, which would have been highly injurious in the inflammatory stage; but it immediately put an end to all the symptoms. He had a quiet sleep; and awoke without delirium, and with a strong pulse. Now it is just the same in children. After hydrocephalus has lasted some time, we may judge by the pulse and paleness of the patient, that evacuations will *increase* instead of *diminishing* the mischief;\* and it is right to be aware, that just such a state will come on without inflammation. There may be a state of irritation and debility, without inflammation having been present;—as we shall see in the disease called “delirium tremens.”

### b. *Apoplexia Exsanguinea.*

I stated<sup>b</sup> that children were occasionally subject to hydrocephalus from mere exhaustion; that their pupils became dilated; that they would fall into a state of coma, and perhaps be convulsed; and that if we bled them, we should destroy life; whereas, if we gave ammonia and beef-tea, and supported them well, they generally recovered. In like manner adults will sometimes fall into a state of apoplexy from downright exhaustion; and this is called “*apoplexia exsanguinea*.” Dr. Abercrombie says, that he has seen adults comatose and collapsed; the pulse not full; the lips not purple; and the face not turgid.

*Symptoms.*—It will be recollected that, in apoplexy, the face is turgid, and more or less livid;<sup>c</sup> but, in this form of the disease, the face is collapsed and pale; and, notwithstanding the pulse may be full, Dr. Abercrombie states that, in this condition, the diagnosis is to be drawn from the paleness of the face. He says, that he has seen it arise from neglected diarrhoea. Starvation might probably sometimes have the same effect. He says that he has seen the state, in an old lady, amount to a loss of memory and squinting; and he mentions one case, in which a person was regularly deaf (paralyzed in one of the senses) when in the erect posture;—when less blood goes to the brain, and more freely escapes from it; whereas, as soon as the patient lay down, the deafness ceased, and the face became flushed.

*Treatment.*—It is very necessary, in looking at a case of apoplexy, to ascertain whether it is of the kind we see in nineteen cases out of twenty; or whether it arises from a state of exhaustion of the brain. If it be a case of the latter descrip-

\* Of the whole number of fatal cases of diseases in infancy, a great proportion occur from this inappropriate or undue application of exhausting remedies. This observation may have a salutary effect in checking the ardour of many young practitioners; who are apt to think, that if they have only bled, and purged, and given calomel enough, they have done their duty; when, in fact, in subduing a former, they have excited a new disease; which they have not understood, and which has led to the fatal result.—“*Diseases of the Nervous System*; by Marshall Hall, M.D.” 1841. Paragraph 736.

<sup>b</sup> See Page 528.

<sup>c</sup> See Page 512.

tion,—if the face be pale and collapsed, we have reason to believe that the patient has had causes of debility applied; and then, certainly, it would be necessary to give ammonia. Ammonia is preferable to wine; because wine might perhaps induce too great a stimulation of the brain, which would last afterwards; whereas the stimulus of ammonia is very evanescent. There will of course occur cases, in which we shall be unable to make up our minds as to what ought to be done. The same circumstance occurs in the treatment of inflammation. I have already stated<sup>a</sup> that, at last, we are unable to make up our minds, how far there is *irritation*, and how far *inflammation*. In such cases it is best to mix the treatment. We should evacuate as much as we can; apply blisters rather than leeches, leeches rather than cupping, and cupping rather than bleeding at the arm; and, at the same time, allow a moderate diet and ammonia. The operation of the latter very soon ceases; and, if we see that it does harm, the effect is over, and there is no serious mischief. This is the advantage of combining both plans.

### SECTION III.—EFFECTS OF A SHOCK, MENTAL OR PHYSICAL.

*Mental Shock.*—[The effect of a *mental shock* is, frequently, a state bordering on delirium, or mania. Suicide is a frequent event at such a moment. There are a sense of weight or pain about the head, and sleeplessness. There is great danger of mistaking the symptoms for mere mental affliction. We ought to *treat* it as a serious malady. The timely use of the lancet, would have prevented many an act of suicide.

A. B., aged forty, became ruined in character and fortune; and, when in the midst of his difficulties, experienced a sense of heaviness and pressure in the head, and passed sleepless nights. After several days he attempted suicide, by dividing the muscles and blood-vessels of the arm deeply. He lost a large quantity of blood, and became faint. On recovering from this state, he said to his medical friend—“Had you bled me a few days ago, I should not have done this act; had Sir Samuel Romilly been timely bled, he would still have been alive!” From this time all the symptoms subsided.

I<sup>b</sup> twice visited, at the distance of ten miles from town, Miss ——. She was of a chlorotic pallor; and had experienced a *heart-rending* disappointment. She was in bed; affected with a rather frequent pulse, slight delirium, alternating with equally slight coma, or dozing, a mucous rattle in the respiration, a tympanitic state of the abdomen, with the discharge of offensive *fæces*. In spite of every remedy, she gradually sunk, and expired. This case appears to have been the effect of a mental shock. At least, no other causes of those effects could be discovered.

*Traumatic Delirium.*—To the same class of affections, doubtless, belongs the nervous delirium, or “delirium traumaticum,” described by Dupuytren, as following serious accidents and operations. It is characterized by sleeplessness, delirium, and jactitation; the eyes are injected; the countenance is flushed and animated; the forehead covered with profuse perspiration; the patient is insensible to the pain of his accident or operation; there is no fever or constipation. The patient may fall asleep, awake composed and rational, relapse, &c. It is a short mania of five or six days’ duration; and attended by great danger. There are no distinct traces of morbid change, on examination. The brain and spinal marrow are found apparently healthy. The remedy proposed by Dupuytren is a small enema, with five or six drops of *Tinctura Opii*, repeated three or four times, at intervals of six hours.

This affection is frequent after attempts at suicide. The shock of an operation, not in itself extremely formidable, has proved fatal. But what is more remarkable

<sup>a</sup> See Page 131.

<sup>b</sup> Dr. Marshall Hall.

is, that this event has frequently been foretold in the most positive terms by the patient. These facts cannot be uninteresting to the physiologist and pathologist.<sup>a</sup>]

#### SECTION IV.—DELIRIUM TREMENS.

I now proceed to speak of a disease which resembles, in many of its symptoms, inflammation of the brain; and yet, in a great number of cases, it would prove fatal, if treated on the common principles applicable to phrenitis. The disease to which I allude, is called “delirium tremens;” which is rather an improper term, because the delirium cannot tremble. It would be better to say “delirium *cum tremore*,” but it has derived its name from the patient’s being in a state of agitation, and being delirious. I speak of it now, because it may be readily contrasted with the delirium of phrenitis,<sup>b</sup> arachnitis,<sup>c</sup> and hydrocephalus acutus;<sup>d</sup> of which I have already spoken.

*Causes.*—This state of delirium with universal tremor, is rather the effect of morbid irritability than of inflammation. It is such a state as occurs in fever, when delirium exists. It is very much the same condition, as that which recurs after great loss of blood; in which there is headache, vertigo, and disturbance of the mind. It is just such a state, as frequently takes place after active inflammation of the brain. When the last stage of phrenitis has arrived, the patient will fall into a state of irritation of the brain, which resembles delirium tremens.

It is a disease which occurs in adults, and not in young subjects; except in affections which I have already mentioned as analogous to this.<sup>e</sup> It generally occurs, too, in adults who have been addicted to dram-drinking;—not *always*, but *generally*. It is said to have appeared sometimes after acute rheumatism, sometimes after scarlet fever, sometimes after typhus fever, sometimes after injuries of the head, and immediately after apoplectic and paralytic fits, and sometimes after long continued exposure to lead; but the most frequent circumstance producing the disease, is a continued habit of dram-drinking.

*Symptoms.*—As the disease is, for the most part, one not of *inflammation* but of *irritation*, the face is not flushed, but pale. When I described that state in infants which is frequently mistaken for arachnitis, and in which stimulants are proper, I mentioned that the face is not flushed, but pale; or that if it be flushed, it is only transiently.<sup>f</sup> Now in this disease the circumstances are quite analogous. The eyes are not red, and there is no intolerance of light or noise;—at least nothing worthy of being mentioned, compared with what is seen in phrenitis; and frequently there is none whatever. The tongue is generally neither dry, brown, rough, nor white,—as it is in inflammation; but is usually moist, and covered all over with a white, soft, creamy mucus. Generally there is no great heat of body; and the skin is not dry, as in most inflammations; but is covered by a profuse sticky, clammy perspiration; and sometimes this is of an offensive character. If the perspiration be clammy, of course it is a morbid secretion. It is secreted in a morbid state, or it would not be clammy; and if it be secreted morbid as to *consistency*, it may be secreted morbid as to *smell*;—so that the perspiration is not only clammy, but offensive. This is a very common occurrence. The pulse is quick;—a circumstance which may be expected under simple *irritation*, as well as under *inflammation*; and at last it becomes very rapid; but it is neither full nor hard.

*Approach of Delirium.*—At length, as in other diseases, the pulse will become fluttering;—what is called, by some writers, “*pulsus vermicularis*,”—like the undulation of a worm. There is constant watchfulness in the disease;—the patient can get no sleep; and there is constant delirious talking. He is constantly endeavouring to get out of bed, and out of the room; but we may easily induce him

<sup>a</sup> “Diseases of the Nervous System; by Marshall Hall, M. D.” 1841. Pages 357 to 359.

<sup>b</sup> See Page 482.

<sup>c</sup> See Page 483.

<sup>d</sup> See Page 502.

<sup>e</sup> See Page 529.

<sup>f</sup> See Page 528.

to lie down in bed, or lead him back to it, if he have escaped. There are no violent efforts in the disease;—no such efforts as are seen in “*delirium ferox*,” but he is everlastingly chattering, and everlastingly restless; so that he will go on talking, and trying to get out of bed. He will sit up too in bed;—constantly moving his hands and arms backwards and forwards, but not violently; and then, in the midst of all this, he tries to leave his bed. The delirium generally respects imagined wrongs; and an imagined unfortunate state of private affairs. He fancies that his affairs are in a dilapidated state; and that different persons are endeavouring to injure him. There is this extraordinary extravagance about imagined wrongs, and deranged affairs, rather than any preposterous hallucination. There is, of course, great anxiety occasioned by the patient dwelling on these topics. The attention of the patient may be excited to any subject, for a moment; but, a moment afterwards, he has forgotten what the subject was. His ideas roll off again to some other matter; and he forgets what he had been talking about. There is no spite,—no malice in this disease; the patient does not attempt to injure those around him. The whole body is in a state of tremor; and the tongue among other parts. There is great debility, with loss of appetite. There is likewise a catching of the tendons (called “*subsultus tendinum*”); and a picking of the bed-clothes. It is common, in cerebral affections attended with delirium,<sup>a</sup> for a person to be catching at something which he imagines to be before him; and now and then there is hiccup.

*Premonitory Symptoms.*—The attack is sometimes very slow, and sometimes very sudden. If it come on slowly, there is at first anorexia, loss of appetite, and want of sleep at night; besides which, the patient is restless during the whole of the day;—fidgety, and plaguing people about him with his own matters. The eye, at the same time, is observed to be dull.

*Stages of the Disease.*—[Most writers on this subject, have adopted Dr. Blake's division of the disease into three stages;—as being best calculated to obviate the obscurity and confusion in which its history was formerly involved, and to direct us to our mode of treatment. The first stage is characterized by general debility, anxiety of countenance, depression of spirits, a slow pulse (frequently as low as forty-four in a minute), interrupted slumbers, cramp in the extremities, vertigo, nausea, and occasional vomiting. By timely and judicious treatment, its further progress may be arrested; and, by subsequent prudence on the part of the patient, its recurrence may be prevented. Generally, however, after a shorter or longer period,—according to the constitution, age, and previous habits of the patient,—it is succeeded by the second stage, or that of delirium; the symptoms of which have been already described.<sup>b</sup> Either these symptoms increase in violence; and others (which very nearly resemble those of the last stage of typhus) supervening, the patient dies suddenly in a convulsion; or the long-continued delirium—with *subsultus tendinum*, picking of the bed-clothes, &c.—is succeeded by a short interval of quietude, and he expires without a struggle; or, after two or three days, or (it may be) a week, yawning and drowsiness come on, and are followed by sleep; which is generally profound and of long duration;—lasting from six to twelve or eighteen hours. The patient wakes collected, and greatly refreshed; and his recovery may be looked upon as almost certain.<sup>c</sup>]

*Diagnosis.*—The diagnosis of the disease, therefore, appears to be made out from the weakness of the pulse; the want of violence in the patient; the want of a flushing in the face, and redness of the eyes; the want of furious delirium; the want of sleep; the circumstance of the patient being in a state of tremor of the whole body, with a tongue not dry, but covered with a creamy mucus; with a skin not dry, but sweating profusely; the circumstance of the patient talking incessantly about his own affairs,—about some imagined distress; his attempting to get

<sup>a</sup> From “*delirio*,” to *rave*.

<sup>c</sup> “*Cyclopædia of Practical Medicine*,” Volume 1; Page 511.

<sup>b</sup> See Page 531.

out of bed; and his being everlastingly restless, but easily managed and laid down, or brought back to bed.

*Prognosis.*—[Some difficulty will be experienced in forming a just prognosis in this disease;—it being so very insidious in its effects. In giving it we must, of course, be guided by the constitution and habits of the patient; as well as by the violence of the symptoms with which he is affected. In a worn-out and diseased habit, much addicted to the abuse of spirituous liquors or diffusible stimuli of any sort, and one that has, perhaps, suffered frequent attacks of this disease, more is to be feared; as, in such cases, the indirect debility (or exhaustion) may be such, as to require an effort too great for the worn-out nervous system to support, in its endeavours to restore order. On the contrary, in a young and healthy subject, this disease is seldom fatal when properly treated; but, in either case, we should be considerably assisted in forming our opinion, by attention to the favourable or unfavourable symptoms already detailed.<sup>a</sup>

The state of the pulse, though not always an infallible guide in disease, has been to me a comparatively sure one in this complaint; as, when its frequency did not exceed one hundred strokes in a minute, I looked on the patient (generally speaking) as safe; but, on the contrary, when (from its rapidity and the tremor of the hands) it could scarcely be counted, I considered him in imminent danger.<sup>b</sup>

*Treatment: Opium.*—The remedy for the disease is opium, in full and repeated doses. One or two grains will not be sufficient. It is necessary to give from three to five grains; and to repeat these doses according to circumstances. In some cases, it is necessary to give five grains every six or eight hours; and this plan must be continued till sleep is procured. Three grains would be a proper dose to begin with; and, while the patient continues well, it need only be given in small doses; but full doses must be resumed when the symptoms return. Dr. Sutton<sup>c</sup> says, he learned the practice in Kent; where there is a great deal of the affection;—on account of the people being so addicted to dram-drinking. Smuggling is carried on to a great extent, on the east coast of Kent; and the people therefore drink to great excess; and delirium tremens consequently prevails extensively. He found eminent practitioners adopting two different modes of treatment;—the one antiphlogistic, and the other narcotic; and he soon saw the superiority of the latter.

I was sent for to a case, which had been phrenitis, and properly treated as such; but it afterwards became delirium tremens. The patient's pulse was rapid and soft; his tongue not dry and his body not hot; but there were delirium and tremor. Four grains of opium were sufficient to send him to sleep; and he awoke almost well.

This treatment with opium, which requires to be backed by good nourishment, is the same that should be adopted after profuse hæmorrhage, and after the spurious form of hydrocephalus, if I may use the expression;—that state of the system, which resembles hydrocephalus in appearance only.<sup>d</sup> It is also the treatment we should adopt in delirium mitius; and wherever there is great irritation of the brain with debility.

Recovery from this disease, under the opiate treatment, is very frequent; whereas, under any other, patients continually die. However, the affection will cease spontaneously, like almost any other complaint. It lasts, in general, from three days to a week; and patients may then sink gradually, or pretty suddenly; or, at the end of that time, they may recover; but it is very rare. Now and then, it has been known to be followed by apoplexy or mania. I recollect seeing a case of this description, which terminated in complete mania. If the disease yield under the

<sup>a</sup> See Pages 531 and 532.

<sup>b</sup> "A Practical Treatise on Delirium Tremens; by Andrew Blake, M. D." Pages 40 to 42. (First Edition.)

<sup>c</sup> "Tracts on Delirium Tremens, Peritonitis, and some other Internal Inflammatory Affections; and on Gout; by Thomas Sutton, M. D." This work is short and excellent; and it will be worth the while of every gentleman to read it.

<sup>d</sup> See Page 528.

use of opium, the opium may be continued twice a day, for some little time, and then relinquished slowly; just as the symptoms of the disease decline.

*Ptyalism, Stimulants, &c.*—Some writers have recommended a gentle ptyalism to be produced; and some, notwithstanding the profuse sweat, have advised cold affusion. I have no experience of either of these modes. Good food undoubtedly is necessary; and sometimes it is found requisite to indulge the patient with drams. In all cases where patients have acquired bad habits, they must be indulged, whenever a great demand is made upon the system,—as after an operation or an accident. The system has become accustomed to drams; and without them it cannot conduct its affairs; and we must allow them, or any thing else that has become a bad habit. However, good food is generally necessary;—beef-tea and milk. Slops the patient cannot take.

*Complicated with Inflammation.*—Notwithstanding, however, that this is the frequent and most common character of the disease, the disease is not always of this nature. We may have patients with this mild state of delirium, easily led back to bed, easily put down in bed, and trembling from head to foot; with the tongue in a state of tremor too; and yet inflammation may be present; requiring to be treated as we would treat phrenitis. In such a case as this, we find sufficient signs to point out that it is a disease, not of irritation merely, but of inflammation in some degree. The patient will be more or less flushed; his pulse more or less full and firm; and the delirium will be rather violent. I have seen cases deserving to be called “delirium tremens,” in which the patient was trembling, talking about his own affairs, believing that he was an injured person, easily led back to bed, with a moist skin and a moist tongue; and yet this disease was not benefited by opium, and was not cured till bleeding and starvation were had recourse to. It is therefore necessary to remember, that we are not to prescribe for a name, but for the condition of the patient. There may be a pulse that will justify us, if not in bleeding, in purging;—at any rate, in abstaining from opium. Antiphlogistic<sup>a</sup> treatment is sometimes required in this disease; but usually it is only required in moderation; and there may be cases where it is perfectly right to employ moderate antiphlogistic treatment, and to give opium also. We may administer opium; but it will be fruitless, unless we adopt some antiphlogistic measures. We must keep the head cool; and ice will effect this purpose best. Leeches may also be applied. It is said by Dr. Latham, whose experience must be greater than mine (for I only see cases now and then), that blisters are always bad in this disease; and he says, that, in decided cases of the affection,—although it may have come on after apoplexy,—opium is equally useful;—provided it is a proper case for opium. The circumstance of the affection coming on after apoplexy, does not prevent opium from being equally proper;—that is, if the delirium do not arise from *inflammation*, but from mere *irritation*. After inflammation of any organ whatever, when we have put antiphlogistic treatment in force, opium is proper. I mentioned,<sup>b</sup> in speaking of inflammation, that when we have reduced the powers of the patient, and mastered the disease, opium answers a good purpose; because a state of irritation is likely to come on; but if we gave it before, it would be likely to do harm. This disease has nothing peculiar in it; it is merely an instance of a general state of irritation. Opium is found useful in irritation of almost all the various organs of the body; provided that no inflammation exists; or that any which does exist be removed by proper treatment, before administering the opium.

*Morbid Appearances.*—It is said that after death, a little congestion may be found in the head; and sometimes a slight effusion.

[The utility of opium in delirium tremens can scarcely be questioned, but that the treatment of the disease by means of this drug is the only method which commands great success, is far from being in accordance with the experience of many practitioners in the United States. Indeed, the plan formerly adopted by some, of persevering in the administration of large and repeated doses of opium until

<sup>a</sup> From *anti*, against; and *φλεγω*, to burn.

<sup>b</sup> See Page 129.

sleep is procured, is now very much abandoned. Some, indeed, place their main reliance on entirely different measures. Thus, Dr. Klapp, of this city, depends in great measure upon the use of emetics, whilst Dr. Gerhard has met with the most remarkable success from the employment of graduated doses of alcoholic stimulants. The results of the latter method, in the men's wards at the Philadelphia Almshouse, under the charge of Dr. Gerhard, have been such as scarcely to leave room for doubt that the disease may very generally be brought to a favourable issue in this way. This plan of treatment is objected to, however, on the ground that the patient is confirmed in his habits, and more liable to relapse. However forcible such an argument in reference to mild cases, it should have no weight in view of those severe forms of the disease in which life is in danger. If alcoholic stimulants afford the best chance of preventing a fatal result, they must be resorted to without reference to ulterior considerations.

A mixed opiate and stimulant treatment is the one most commonly, perhaps, resorted to. Thus, the patient may be put upon the use of carb. of ammonia with assafoetida, valerian, or some other antispasmodic, or of alcoholic stimulants, and an opiate be administered in the evening, if necessary. At the same time, mustard foot-baths, enemata, blisters, cold to the head, &c., may be advantageously resorted to, especially where the bowels are confined, and the head hot, with other evidences of vascular excitement. Such is the plan generally resorted to by me in the Pennsylvania Hospital; and I think it decidedly preferable to the practice formerly adopted, of administering large doses of opium at regular intervals throughout every period of the twenty-four hours, until sleep is procured.—T. S.]

## SECTION V.—CEREBRAL SYMPTOMS FROM CHLOROSIS, DROPSY, AND ISCHURIA.

[Besides those remote causes already mentioned, symptoms of encephalic disturbance may arise from the presence of various other diseases.

*Chlorosis*.—The influence of that anæmial state, which occurs in chlorosis, upon the encephalon, well deserves our attention. Dr. M. Hall mentions a case which was characterized by the presence of "mild delirium, succeeded by slight coma, which was intermittent in its character; the respiration became momentarily suspended, and the inspiration sudden and sometimes *catching*; the abdomen tympanitic, with the escape of much flatus; the pulse 130 or 140, full and throbbing. On examination, there was an effusion of opaque lymph under the arachnoid, at the summit and base of the brain; together with an effusion of serum into each ventricle.

"This case is important in every point of view. It is important with regard to the nature of the disease of which it is an example;—demonstrating, as it does, the tendency of that disease to induce, not merely external dropsy, but effusion under the arachnoid, into the pleura, and into the pulmonary cellular membrane, &c. It is important, too, as an unequivocal representation of the disposition to such organic changes, in cases of bloodlessness and exhaustion. It is also important as establishing the fact, that not only serous effusion, but the deposition of coagulable lymph, may take place, without inflammatory action, in similar circumstances; and that consequently, such deposit of lymph is no proof of inflammation.

*Dropsy*.—"In the midst of dropsy, the patient is not unfrequently attacked with symptoms denoting a cerebral or true spinal affection. There are delirium, or coma, or convulsions; apoplexy, hæmorrhage, hemiplegia; or meningitis.

"I<sup>a</sup> have particularly noted such an affection in children, in exanthematous dropsy. Dr. Wells mentions this affection.<sup>b</sup> Dr. Bright gives such a case;<sup>c</sup> where, on examination, 'a slight serous effusion under the arachnoid' was found.

<sup>a</sup> Dr. Marshall Hall.

<sup>b</sup> "Transactions of a Society for Promoting Medical and Surgical Knowledge," Volume 3; Page 177.

<sup>c</sup> "Medical Reports;" Volume 1; Page 97.

*Ischuria*.—"The next disease to which I<sup>a</sup> must refer, as intimately connected with the brain, is ischuria, or suppression of urine; to which may be added other morbid conditions of this secretion, besides that marked by the presence of albumen. Dr. Prout, Dr. Abercrombie, and Dr. Wilson, have lately treated this subject.

"There is frequently considerable disease of the kidneys. The suppression may be partial, or complete; it leads to fever, thirst, a urinous smell of the perspiration and taste in the mouth, vomiting, hiccup, delirium, coma, convulsions."<sup>b</sup>]

## CHAPTER V.

### TUMOURS IN THE BRAIN.

I mentioned<sup>c</sup> that pus, when formed, might be found either in a cyst or diffused; that sometimes the surrounding part is in a state of irritation, and sometimes perfectly healthy; and that sometimes, by the presence of pus, the surrounding parts become diseased.

*Scrofulous Tubercles*.—But, besides this, we frequently have tumours of a scrofulous nature, in the brain and nerves. These occur most frequently in infancy; but they are not so often found in very young infants, as in those a little older. They are so much more frequent in infants than adults, that even in phthisical adults we seldom see them. They are most usually observed in the hemispheres of the brain; and they are found more frequently in the cervical, than in other portions of the spinal marrow. I recollect a case of paralysis of the lower extremities, in which a scrofulous tumour was found in the cervical region of the spinal marrow. It is a constant observation, that scrofulous tumours of this kind, are found more frequently in that situation, than in any other. They frequently appear to have originated, both in the head and spinal marrow, in the "pia mater;" which corresponds with the cellular membrane in other parts of the body. They are not numerous in the nervous system; for it is common to find but one. Like the tubercles of other parts, they are of all sizes; and they agree with them in another respect;—they are sometimes inclosed in a cyst, and sometimes they have none. I have seen many preparations, exhibiting a large mass of scrofulous deposit in the cerebellum. There was in Bethlehem Hospital an idiot, who laboured under St. Vitus's dance. He was also addicted to the vice of masturbation; and in his brain there was this appearance;—a scrofulous deposition in the cerebellum.

The symptoms of a scrofulous tumour will be inflammation, paralysis,<sup>d</sup> and convulsions.<sup>e</sup> The nature of the substance deposited can make no difference. If it produce irritation, we may have convulsions of various kinds;—epilepsy, St. Vitus's dance, and so on;—any convulsions, or spasmodic diseases; and any sort of paralytic affection; together with pain in the head, delirium, and symptoms indicating inflammation.

*Scirrhus and Osseous Tumours*.—We sometimes find *scirrhus* tumours in the head; and they are sometimes enormously large;—so as to occupy the greater part of the hemisphere. They have also been seen to occupy the entire cerebellum. Sometimes, in the membranes, they are of an exceedingly hard character;—having undergone a cartilaginous, or fibro-cartilaginous change. Sometimes this

<sup>a</sup> Dr. Marshall Hall.

<sup>b</sup> "Diseases of the Nervous System; by Marshall Hall, M. D." 1841. Pages 355 and 356.

<sup>c</sup> See Pages 488 and 489.

<sup>d</sup> From *παρᾶλυναι*, to weaken.

<sup>e</sup> From "*convello*," to pull together.

transformation proceeds even to the formation of bone;—so that bony tumours are found within the head, within the brain, and upon the membranes; and there are likewise bony tumours in the cerebellum. We know that it is common to find plates of bone along the longitudinal sinus; and sometimes a spicula of bone (an exostosis) has been seen. The symptoms of all these tumours are the same.

*Encephaloid Tumours.*—Occasionally we have *encephaloid* tumours in the brain;—a deposition of new matter, which is not seen in the healthy body; and which, being *like* brain though different in its nature, has been called “encephaloid.”<sup>a</sup> Very frequently, hæmorrhage takes place from it;—so that it becomes a bloody tumour; and used to be called “*fungus hæmatodes*.” This most frequently occurs in young subjects. It was supposed to be the cancer of young subjects. It is called by Dr. Hooper “*hæmatoma*.”<sup>b</sup> When cut into, it (like the brain) is soft and white; and in some parts it is red.

*Melanosis.*—Sometimes we may have that black deposit in the brain, which is called “*melanosis*.”<sup>c</sup> This is not a malignant disease;—doing no harm except, mechanically, by its bulk; but it frequently coexists with scirrhus, and with encephaloid disease.

Scirrhus tumours (that is to say, fibrous formations, transformations, and ossifications) are found much more frequently in the membranes, than in the brain itself; but encephaloid, melanotic, and scrofulous deposits, are found most frequently in the brain.

*Encysted Tumours.*—Encysted tumours, of all kinds, are found in the head, and spinal canal. Sometimes these common encysted tumours, or serous cysts (called “*hydatids*” in common medical language, though they are not so), are found in the “*plexus choroides*,” and they are just the same on either side. Small cysts are frequently seen in the membranes, as well as in the “*plexus choroides*,” and sometimes they are found in the substance of the brain itself. Dr. Hooper has given some very admirable representations of these cysts.

*Hydatids.*—Besides these encysted tumours, real hydatids are occasionally found in the substance of the brain, as well as in the spinal marrow; and on the exterior of these parasitical animals we occasionally find an appendage, approaching to a tail. These animals are also frequently found in the brute creation. The contents of the serous cysts (not hydatids) are very various. Like the contents of serous cysts in other parts of the body, they are sometimes clear liquid, sometimes soft pulsatious substance, and sometimes blood.

*Obscurity of the Symptoms during Life.*—No one can tell beforehand, the existence of any of these things. Some of the diseases are present, of which I formerly spoke;—such as delirium,<sup>d</sup> convulsions,<sup>e</sup> paralysis,<sup>f</sup> or pains in the head;<sup>g</sup> sensations of coldness and of heat;—all sorts of uneasy sensations; and we suspect, from the continuance of these symptoms, that there must be organic disease. When we find paralysis, we suppose that organic disease is coming on; but it is almost impossible to say what it is. If we see organic disease in another part of the body, (“*fungus hæmatodes* in the extremities,” for instance,) and the patient then becomes paralytic, and has convulsions,—we may suppose that the same disease which has taken place externally, is coming on in the head; but the symptoms will only enable us to say, that we *presume* there is organic disease.

All these things (scirrhus, encephaloid matter, melanosis, and scrofulous formations) which occur in the head and in the spinal canal, are also frequently found in the distant nerves; where they cause only *partial* palsy.

## CHAPTER VI.

## AFFECTIONS OF THE INTELLECT.

*Mental Functions depend on the Size of the Brain.*—Having spoken of the diseases occurring in the brain, I now proceed to speak of those original aberrations of formation which are occasionally discovered. It is well known, that the nervous system is more complicated in the series of animals, as we rise from those which display the least mental functions, till we arrive at man, who displays the very highest intellectual faculties. The lower the animal is, the smaller is the brain; and in the very lowest we have nothing that corresponds to brain; but where there is mind, there must be something to direct the functions;—to experience sensation, there must be an organ. Accordingly, it is universally allowed, that the nervous system receives additions, in proportion as we ascend in the scale of being.

In the ninety-fourth number of the “*Edinburgh Review*,”<sup>a</sup> which at first was disposed to laugh at this as nonsense, we find the following remarks:—“As we ascend the scale, we are enabled to associate every faculty which gives superiority, with some addition to the nervous mass; even from the smallest indications of sensation and will, up to the highest degree of sensibility, judgment, and expression.—We discern a line of ganglions; then a spinal marrow; a cerebellum is then added; and, lastly, a brain. The latter is observed to be improved in structure, and (with reference to the spinal marrow and nerves) augmented in volume, more and more, until we reach the human brain;—each addition being marked by some addition or amplification of the powers of the animal; until, in man, we behold it possessing some parts of which animals are destitute, and wanting none which theirs possess.” It may therefore be supposed, that if certain parts of the brain be deficient, the mind will, in a correspondent manner, be defective; and this, accordingly, is the case. I will first enumerate, as morbid anatomists do, the deficiencies which are found in the brain;—not referring at all to phrenology; but taking up the subject as it is treated by morbid anatomists.

## SECTION I.—MALFORMATIONS OF THE BRAIN.

*Deficiency of the Convolutions.*—In the first place it is found, in the higher beings who have a deficiency of the cerebral mass in any respect, that the convolutions are too small, or that there are too few of them on one or both sides. It is well known, of course, that the convolutions give a great extent of surface to the brain;—just as the “*valvulæ conniventes*” of the intestines, give an increase of surface to the interior of that canal; so that if there be fewer convolutions than usual, there must be so much less external part of the brain. Thus we find occasionally, in human beings, that there are too few convolutions on one or both sides; or we find them too small. Occasionally, one or two convolutions, usually found, have been entirely absent.

*Deficiency of the Hemispheres.*—Secondly, all the upper parts of the hemispheres, down to the vault of the ventricles, have been found to be absent; so that the ventricles lie entirely open, or are only covered by a serous membrane;—that is to say, in all probability, by the arachnoid coat which lines them. Sometimes one lobe of the brain has been absolutely wanting; and sometimes one has been only too small.

*Deficiency of the Thalami, and Corpora Striata.*—Thirdly, the “*thalami*

<sup>a</sup> Volume 47; Pages 442 and 443. (May, 1828.)

nervorum opticorum," and the "corpora striata," on one side or both, have been found too small, or have been absolutely wanting; or their place has been supplied by a cyst; though sometimes it has not. A deficiency is sometimes seen in the gray substance of the brain; and sometimes in the *white* substance. If the hemispheres be wanting, there is nothing beyond the "crura cerebri," except a few scattered fibres,—such as are seen in the fetus before the hemispheres are formed; and, indeed, there are then no central white parts.

*Deficiency of the Medullary Matter.*—Fourthly, the central white parts are found, sometimes, in a state of deficient development. Occasionally the "corpus callosum" is a mere membrane; and it has been found absolutely wanting, in an idiot thirty years of age. In some brutes (for instance, birds and reptiles) the same is observed naturally. There is no "corpus callosum," nor any fornix; and therefore such a brain as we have mentioned, resembles the brain of some brutes.

When there is this smallness or deficiency of certain parts, other parts are not naturally so developed in man as they are in brutes. They appear larger in such a human being, but it is merely by comparison; and it is found that the parts are larger in brutes. They appear larger, if the other parts be wanting; but it is merely a deception. We never find the "tubercula quadrigemina" a hollow tube, as in birds;—we never find the fourth ventricle so large, as in some brutes. The middle lobes of the cerebrum, though naturally smaller in brutes than in man, are in this case just as large as those in man.

*Deficiency of the Cerebellum.*—The cerebellum is sometimes deficient. It may be small, or the medullary centre may be small, or the lobes may be small;—they have been seen to be a mere sac. This is observed in some brutes; and sometimes in the human embryo. The reason of this extraordinary formation is, that development has ceased, in most instances, at a certain period. We know that the brain, in the human body, is different at first from what it is at last; and occasionally the development of it stops; and, as the adult person grows up, we see that it is totally different from what it is in other beings. When this is the case, the cerebellum is so defective as to be a mere sac; the "tuberculum annulare" is wanting, though the middle lobe of the brain is present; because the "tuberculum annulare" is found to be in proportion to the size of the cerebellum. Where there is no cerebellum, still the "corpora quadrigemina" may exist; because they have a relation, not to the cerebellum, but to the spinal marrow. As to the pineal gland, we find that in all formations of the brain.

*Absence of the Spinal Marrow.*—The cerebrum and cerebellum may be absent, although there is the spinal marrow, and the "medulla oblongata;" but if there be no spinal marrow, it is found that there is neither cerebrum, nor cerebellum, nor "medulla oblongata." As to the spinal marrow itself, it may be entirely absent, and sometimes it is found divided, and it is said that when it is divided into two, the brain is always absent. Sometimes it is only channelled down the centre; and, when this is the case, there are frequently other malformations;—such as a want of brain, or a want of bone in the spine. When there is a channel, it is found to arise from the want of the cortical substance of the spinal marrow; and the channel seems continued all the way up to the fourth ventricle. The division, or the channel, may be large or small; and it may not run the whole extent. The channel itself is found at all ages. Two instances of maniacs are recorded, in one of which two central canals were observed in the spinal marrow, and in another only one. Many brutes have this central canal. Sometimes the spinal marrow is not wanting, but is very small; and sometimes the smallness is local;—occurring only at one spot; just as smallness occurs, sometimes, only in one part of the brain.

*Does not Influence the Nerves.*—It does not follow that the nerves should correspond to this deficiency. There may be a deficiency of the nerves, when the brain is wanting; and a deficiency, too, when the *spinal marrow* is wanting; but occasionally the nerves are found perfect, although the brain and spinal marrow are found wanting. There they are, ready for action; but they want the brain and spinal marrow to put them in motion. When there is this deficiency in the nervous

system, the corresponding parts of the body are sometimes small, and likewise atrophied; yet occasionally the body is perfectly sound,—in all other respects well developed,—even where this deficiency of the nervous system exists; except that the *heart* is never found where there is no *head*. Serres says that *he* has found a heart where there was no head; but nobody else ever did.

Where there is no head, I believe the *lungs* are never found; but, notwithstanding there may be no head, there is always some rudiment of the *alimentary canal*; and for this simple reason;—it is formed first.

*Causes of these Deficiencies.*—The causes of all these wants (smallnesses, and deficiencies) in the nervous system are, first, original defective power; the parts are not developed, through some deficiency in the formative power, independently of all external circumstances. There is a want of power in particular rudiments of the embryo, to develop the various parts. Secondly, they are wanting (I believe) through some previous irritation. They have existed; but some irritation has also existed, which has wasted them, or arrested their progress. Thirdly, pressure (we know) will cause atrophy in future life; and so it will occasionally prevent the development of parts in the *fœtus*.

*Corresponding Deficiency of Intellect.*—If the brain be the organ of mind, which I suppose no one will doubt at the present day, it follows that this deficient development must be attended, in some way or other, by a correspondent deficiency in the mind. If the brain be altogether wanting, there can be no mind at all; and, accordingly, we continually find *fœtuses* formed without any head; and, of course, they cannot manifest mind. But some are born, and live some days, with merely a little brain (if we may call it brain at all) about the “*tuberculum annulare*,” and they will cry, and suck, but do no more; and presently they die. Some (who have just sufficient brain to eat and drink, breathe and grunt) live to be two or three years of age; while others, with a little more brain, will never be able to talk; but they will laugh, cry, be pleased by certain external objects, and displeased with others. Some, again, with more brain, are able to go about; and may be taught to do certain things mechanically, as it were; but they never can exercise judgment. They may be brought to go to bed at a certain time, to get up at a certain time, and to eat at a certain time; but they never go beyond that. Others have sufficient brain to perform the lower offices of life, but not to perform any duties that argue the least intellect; and some, who have still more, can perform the offices of life, but are known in the world as “*innocents*,”—very weak persons. So we go on, till we come to fair average people; and we pass them, and come to very intelligent characters.

However, these intellectual varieties do not depend upon the development of the *whole* of the head. It is found, unquestionably, that they depend upon the development of the interior part; for many of these weak people have heads sufficiently large in every part, except the front. On the other hand, persons with a very small development of all the parts of the brain except the front, may be sufficiently clever persons. These are undoubted facts; and whenever we see a deficient development of the anterior part of the brain, and (necessarily) of the anterior part of the head, it may be taken for granted, that the individual can only manifest a very limited display of intellect.

## SECTION II.—IDIOCY.

Under the term “unsoundness of intellect,” are comprised idiocy and insanity. By “*idiocy*,” or “*idiotism*,” is meant the absence (or rather the deficiency) of intellect;—a deficiency amounting to such a degree, as to disqualify an individual for the common offices of life. Generally speaking, a madman has a *wrong* opinion, or a *wrong* feeling; but an idiot may be generally said to have *none*. The madman is *wrong*; but the idiot is *defective*.

*Legal Definition.*—According to our law, “the individual, in order to be

constituted an idiot, must be unable to number to twenty, or to tell his age, or to answer any common question; by which it may plainly appear that the person has not reason sufficient to discern what is for his advantage or disadvantage." To quote again from the same work (Burn's "Ecclesiastical Law,")—"That man is not an idiot, who has any glimmering of reason; so that he can tell his age, know his parents, or such like common matters."

*Not referable to the External or Internal Senses.*—This deficiency of intellect does not refer to any deficiency of the *external senses*. Idiots can often hear, see, taste, feel, and smell, just as well as other people. Neither does it at all refer to what phrenologists call "the *knowing faculties*;" by which a person judges of music, colours, distance, size, or number, and can recollect words. An idiot may do all these things;—may understand music to a certain extent; may distinguish colours very well; and also size, distance, and numbers; but he may be a complete fool for all that. Many idiots are defective in these respects. Very great idiots know nothing at all; they can merely eat, drink, and slumber. Many persons who can count above twenty are idiots,—notwithstanding what the law says; and medical men would declare many persons to be idiots, although they could count more than a hundred. Some idiots take a great delight in music. I do not know that they can ever be great musicians; but they know what music is;—they understand it; and some sing very well. Some will sketch, likewise, exceedingly well; and some have an excellent memory of words; so that they will remember long passages.

Spurzheim saw, at Hamburgh, a young man, the anterior part of whose brain was favourably developed; but whose forehead, above that part, was scarcely an inch in height; and in whom the movements of the superior parts of the brain were consequently impeded; and he had only the functions of the inferior anterior parts. Now this individual recollected names, numbers, and historical facts; and repeated them all in a mechanical way;—proving that he had a much better memory than many acute men; but the functions of comparison, penetration, and sagacity, were utterly wanting. Spurzheim likewise says that he saw, at a poor-house, a boy who excelled in verbal memory; but as to *judgment* he was an idiot. Dr. Roberts, he says, showed him an idiot, who repeated whole passages from the Bible;—simply from having heard them read. He adds, that he saw an idiotic child, who sang several airs; and if others began to sing, she accompanied them in harmony. It is very possible, therefore, for an idiot to have a pretty tolerable share of those particular faculties, by which a person understands distance, knows colours, can recollect numbers, calculates, distinguishes one object from another, and so on. Neither does the deficiency of *these* things constitute a person an idiot; for many very clever persons are deficient in these particulars. Many clever persons cannot tell red from green; and many clever persons cannot tell "God save the King" from "Rule Britannia." Others, again, can never be made to calculate; and some persons can scarcely keep their own accounts, though otherwise they are reflecting and very clear-headed persons. On the other hand, a person may be an idiot, though he *has* these faculties. An idiot may have them; but their absence does not constitute a man an idiot.

*Varieties of Idiocy.*—There is every degree of deficient intellect;—from the *slightest* to the most *perfect* idiotism;—from one in which an individual merely eats, drinks, discharges his feces and urine at all times and in all places, slobbers, and grunts; up to that in which a person is merely called "imbecile,"—merely (perhaps) "a little soft." All these varieties are seen in life. Such a degree as makes a man "soft," but will not qualify him to have the legal privileges of an idiot, is portrayed by Shakspeare, in the "Twelfth Night," and the "Merry Wives of Windsor." We cannot have a better description of an idiotic, or weak person, than is there given. Sir Andrew Ague-cheek, in the "Twelfth Night," is a very fine illustration of idiocy. He says—"Methinks, sometimes, I have no more wit than a Christian, or an ordinary man has; but I am a great eater of beef, and I believe that does harm to my wit. I would I had bestowed that time on the

tongues, that I have on fencing, dancing, and bear-baiting. O, had I but followed the arts!"<sup>a</sup> Then, in the "Merry Wives of Windsor," an equally sagacious individual, in the character of Slender, says—"Though I cannot remember what I did when you made me drunk, yet I am not altogether an ass. I'll ne'er be drunk whilst I live again, but in honest, civil, godly company, for this trick. If I be drunk, I'll be drunk with those that have the fear of God; and not with drunken knaves."<sup>b</sup> These are two illustrations of individuals, who were weak enough to be below other people; and yet not so weak as to be called downright idiots.

As idiotism (which is, more or less, a deficiency of intellect) varies, so insanity, being a disturbance of the mind, must have infinite varieties. Many faculties of the mind may not be disturbed at all, and others may be disturbed in various proportions; therefore the varieties of insanity can never be perfectly described. No two sane persons are alike in character, any more than in features; and idiots vary in the same way. Many may be idiots to the same degree; but there are various other parts of their character which do not correspond. For example: some have *one* of the faculties of which I have been speaking, and which phrenologists call "the *knowing* faculties," (such as music,) very strong; and others will have *another* faculty very strong; and all may have them in various degrees. So again, some idiots will have one *propensity*,—one *feeling*, very strong; while others will have a *different* propensity or feeling very strong, and some will have several;—so that they vary in their character (to say nothing of idiotism) just like the rest of the world.

*Generally conjoined to other Deficiencies.*—Although the deficiency of any of these knowing faculties, and the deficiency of any feeling (such as good-will towards mankind, revenge, passion, lust, and so on), does not constitute idiotism, yet if the anterior superior part of the brain be so defective as to constitute the individual an idiot, there is seldom so great a defect in that part of the brain, without there being a good deal wrong in other parts. We never find an exceeding degree of monstrosity, without finding minor degrees. When a fœtus is formed without a heart, there are generally supernumerary fingers and toes. Wherever there is a *great* monstrosity of body, there is almost always a *minor* monstrosity; and so when the head is defective in *one* part, to such a degree as to constitute idiocy, there is generally more or less defect in *other* parts. Thus it is very common to see an idiot with these various *knowing* faculties defective, as well as those which constitute him an idiot; and it is very common for him to have certain propensities deficient, or some in excess. There are generally other parts of the brain wrong; although the erroneous state of other parts does not constitute the disease.

*Moral Qualities of Idiots.*—Some idiots, in conformity with all that I have been saying, are exceedingly gentle and good-natured. They never do any harm; and do every thing that they are bid. Some, on the other hand, are very passionate;—never can be trusted; and if we excite their feelings into violent passion, they will take any thing they can procure, and commit murder, if possible. Some are exceedingly mischievous and sly, without being passionate. Some are very much disposed to steal; and will purloin every thing they can. Others, again, are exceedingly low-spirited and gloomy; and some have violent sexual desires. These desires frequently go wrong; partly from some error in the faculty itself, and partly from some deficiency in intellect; so that many of them are, not merely *lustful*, but *beastly* in various ways.

*Prone to Imitation.*—Some are very prone to imitation; and I knew an instance of an idiot, who had all the imitative disposition of a monkey. He was in the workhouse at Clapham. When the surgeon went to visit the patients in the workhouse, he universally observed what was done; and, as soon as the surgeon was gone, he would feel the pulses of the various patients; and get a piece of tape, and begin bandaging up their arms, in order to bleed them. Whatever he saw done, as soon as he had an opportunity, he regularly went and did the same.

<sup>a</sup> Act 1; Scene 3.

<sup>b</sup> Act 1; Scene 1.

Cases of a similar description are mentioned by Pinel, and other writers on insanity. There is no doubt about there being a propensity in the human mind to imitate. All acknowledge this;—phrenologists and anti-phrenologists; and this was so strong in this idiot, who had no sense to restrain him, that it led him to do ridiculous acts.

*Frequently Coexistent with other Diseases.*—This state of mind (idiotism) is very often conjoined—like all diseases of the nervous system—with *other* diseases of the nervous system. It is frequently connected with epilepsy, with chorea, and with paralysis; so that we continually see idiots epileptic, or constantly shaking, and more or less paralytic.

*Brain Deficient, or of Bad Quality.*—When the disease is congenital, there is generally a defect of brain at the superior anterior part; and generally the whole head is too small. Gall says, that if the head be only from fourteen to seventeen inches in circumference, and only from ten to twelve from the root of the nose to the “foramen magnum,” there is always more or less stupidity; that heads of eighteen inches and a half in circumference are small, and give but a mediocrity of talent; and that the full size is from twenty-one to twenty-two inches in circumference. However, idiotism may be produced without a defect of brain. The brain may be plentiful enough; but of bad materials. Dr. Spurzheim says that he dissected an idiot, two years of age, in whom the gray and white substance were of a grayish-blue colour; and, instead of being of the ordinary texture, were of a gelatinous quality. Such a brain as that, although there was plenty of it, was not of a sufficiently good quality to execute its functions. In such an instance, the brain may be very large; but the additional size will not counterbalance the bad quality.

*Quality of the Brain changes with Age.*—It has happened, sometimes, that an individual has been born an idiot, though with a sufficiently well developed head; and the brain has appeared suddenly to improve in quality. The brain improves in quality, as the body grows. It becomes of a different quality, as age advances, to a certain point. It attains a perfection of structure;—not as to *size* and *development* merely, but perfection as to *quality*; and then it afterwards declines (like all other parts of the body) in quality and size. In some individuals, the improvement of quality does not take place at the ordinary period; and the result is, that they remain children longer than other people; and recover from their idiocy at a certain period of life. The same circumstance occurs with regard to puberty. Many instances of this are on record. There is a case mentioned by Wilson, of puberty not taking place till the individual was twenty-eight years of age. There was no beard, or hair on the pubes, and the testicles were small, till the individual was twenty-eight; when suddenly he got a pair of whiskers, a tolerable beard, hair below, and good testicles;—fell in love, and was married. Now it is just the same with the brain altogether. The brain, in some individuals, does not go through its changes of structure at the usual period; so that the individual is sometimes idiotic during the first part of his existence; and, as he grows up, becomes like other people!

*Torpidity of the Brain removed by Accident.*—Most frequently, of course, this is not the case;—the same defective power of development continues; but to illustrate that a torpid brain has sometimes been excited to action by some external circumstance, an instance is mentioned of a boy, who possessed inferior talents till a tile fell on his head; when he began to show great intellect. Dr. Mason Good says, that he knew a lad cured of his idiocy, by a fall from the first floor to the street.<sup>a</sup> As an instance of a similar kind, I may mention that a German writer relates a case of fracture of the skull, by falling from a great height, which cured deafness; and, after the fracture, the man became able to speak. This was upon the same principle as idiots being cured by the fall of a tile or any thing else. In the twenty-fifth volume of the “Philosophical Transactions,” is related a case

<sup>a</sup> “Study of Medicine;” Class 4; Order 1; Genus 6; Species 2; Variety 3.

where want of hearing was cured by a fever. The patient was seventeen years of age, and had never heard; but fever came on, and produced such excitement, that he afterwards heard like other people; and, having heard, he began to speak;—though he had never spoken before.

In cases of torpidity of the brain, where there is such a degree of inactivity as to produce idiotism, we may expect the head to be of the same size as in other persons; and it may be large;—from the brain being blubbery, or from there being a collection of water; as was the case with the head of Cardinal.<sup>a</sup> He ought to have beaten Lord Bacon, and Sir Isaac Newton too, if intellect depended on the mere size of the head.

*Congenital Idiots die early.*—When an idiot is so congenitally, he seldom lives to be above thirty. The defective power which causes the brain to be in such a state, is generally connected with such a want of energy throughout the whole body, that the patient seldom lives beyond thirty; and the greater the idiocy, *cæteris paribus*, the shorter time does he live.

*Idiocy from Excessive Activity of the Brain.*—Just as the brain may be originally torpid and inactive, so it may fall into the same state from excessive action. Precisely the same effect may be produced, if there be excessive action before the brain has acquired its full growth. This is very likely to be the case; for many precocious children, who have been shown to the world as prodigies of talent, have (through the excessive application imposed upon them by their preceptors) become idiotic; and, when they have not become idiotic, they have frequently died. The powers of the body have been exhausted, and some organ more than another has fallen a victim to disease;—so that they have died. Intense application will produce temporary idiotism. Many persons who have bent their minds upon a particular object, and have worked night and day, have frequently fallen into a state of fatuity, which has lasted only for a certain time. The brain has been over-fatigued; and, after a time, it has recovered itself.

*Causes of Idiocy in After-Life.*—Fatuity or idiocy may come on in after-life (when persons have not been born idiotic) from other causes;—for instance, from blows; and from any of the diseases which I before mentioned, when treating of the morbid anatomy of the brain.<sup>b</sup> Any such disease as causes paralysis;—tumours pressing on the anterior part of the head;<sup>c</sup> softening of the anterior lobes (those parts which, I stated, are deficient when a person is a congenital idiot<sup>d</sup>); pressure,<sup>e</sup> softening,<sup>f</sup> or any thing which impedes the functions in any way;—all these will produce idiotism. Fever, being so often accompanied by violent irritation of the brain, will frequently leave idiocy; and insanity has done the same. When persons have been long insane, it is very common for them to lose their faculties altogether. Idiocy is a very common result of insanity.

*Distinction between Fatuity and Idiocy.*—The words “*idiocy*” and “*fatuity*” are not applied indiscriminately. They are nearly the same thing; but “*idiocy*” is generally used, by modern writers, for that which is congenital.—born in a person; while “*fatuity*,” I believe, is generally applied to that imbecility which comes on in after life. The person not having been an idiot at first, but having become so, it is said that “he has become *fatuous*;” and if insanity have been the particular disease which has preceded the imbecility, then the imbecility is called “*dementia*”—(*unmindedness*). Hence, if a person be born an idiot, his case is one of “*idiotism*;” if imbecility come on afterwards, from a common cause, it is called “*fatuity*,” but if it be preceded by insanity,—if it be nothing but the degeneration of insanity, then it is called “*dementia*.”

*Diagnosis.*—If there be great deficiency of the anterior part of the head,—if it be a question of idiotism and imbecility of mind, the case is very easily ascertained: but the head may be large, and yet the person may be an idiot. In the latter case we have to question him as to common circumstances,—to ask him how many half-

<sup>a</sup> See Page 509.

<sup>d</sup> See Page 540.

<sup>b</sup> See Pages 486 and 515.

<sup>c</sup> See Page 522.

<sup>e</sup> See Pages 522 and 536.

<sup>f</sup> See Pages 488 and 516.

pence there are in a sixpence, and how many sixpences in a shilling. If he was born in April, ask him whether he was born the January before; and things of that description. We should ask him questions on the most ordinary subjects; and generally put money before him, and make him count it;—count it as simple pieces of money; and then make him show the value of the whole; and we soon find out whether he is an idiot or not. If he stumble at such questions as these, we may give an opinion that he is not qualified to manage his own affairs.

*Prognosis.*—But besides such an examination as this, it is right to look at the individual's head; and if it appears morbidly small, our opinion as to his idiocy would not be increased, but our prognosis would be exceedingly affected by it. If there is an absolute want of brain, we may take it for granted that the prognosis ought to be unfavourable. There is little hope of its growing to such an extent, as will enable him to be clever, like other people. This will also guide us very much in our attempts at benefiting the sufferer. If there is a great deficiency of brain, all attempts at benefiting him will be hopeless. The schoolmaster may flog; but he will never make any thing of such a head. We might also derive great advantage from inspecting the head, and observing the general character; so as to give directions to his friends how to manage him. We should observe what passion is strong enough to render it necessary for those about the person to be on their guard against it. This will be of use; as well as observing the imperfection of the head, for the purpose of ascertaining the degree of idiotism that exists in the individual.

*Treatment.*—As to curing the disease, all that can be done is to put the patient in as healthful circumstances as possible;—to feed him well, to give him fresh air, and improve his body altogether, on the one hand; and to cultivate particularly those parts of the mind which are best developed, on the other. If there be found any talent for music or calculation, we must make the best of it. A story is told, that may be true, of a boy who was an idiot up to eighteen years of age; when he saw a beautiful girl, and was struck with love for the first time. It shed such a flame throughout his brain, that he became as clever as the rest of the boys in the village. I have no idea of love being so employed; but if we find a faculty tolerably strong, it should be made the most of;—whether it be an intellectual or a knowing faculty; and if other faculties be not excited by it, yet it may be strengthened, and the individual may be rendered much less deficient than he otherwise would be. He may be unable to gain the command of *all* his faculties; but, by strengthening *one*, he may be rendered not so miserable an object, as if he were altogether neglected. This is an important point; because to set down an individual as an idiot, when he has some one faculty that might be made something of, would be cruel; and if we see the development of any thing that would enable us to make the experiment, it ought not to be passed by.

*Cretinism.*—With respect to the importance of good air and good food, in lessening idiotism, I may mention that particular form of idiotism, called “cretinism;” which is produced by bad air or bad water. I should conceive there can be no doubt on the subject. It is found in the valleys of the Alps. It is impossible to travel in Switzerland among any of the valleys, without seeing plenty of cretins. The air is stagnant and wet;—full of the exhalations from marshy ground. The water, for the most part, is very bad: and the people are so ignorant, in many parts, that they drink water containing a great deal of chalk, although good is to be had. They are miserable objects;—mostly always short. In fact, they are dwarfs; and, in general, have enormous heads. Their features are shrivelled; they look like decayed autumnal leaves, or something like a shrivelled apple; and all of them have noses resembling the “ace of spades.” Their limbs are soft and flabby; their mouths are wide,—extending from ear to ear; their lips are very thick; and they have a dry-looking skin. All of them are more or less idiotic, and many of them have a goitre;—an enlargement of the thyroid<sup>a</sup> gland.

These poor creatures are found, after death, to have the bones of the head very

<sup>a</sup> From *Scutum*, a shield; and *eidēs*, resemblance.

thick; and sometimes there is a quantity of water in the head. The cavity of the skull is not so large as the external appearance of the head would lead us to suppose. Sometimes the diminished capacity arises from the excessive quantity of bone, and sometimes from a collection of water. In other cases the brain, although large enough, is of bad quality. The tongue, in some cretins, is hypertrophied;—too large for the mouth; and a large number of them are deaf and dumb. There is a great difference in their dispositions. Some should never be trusted;—they are such destructive creatures, that they do all the mischief they can; while others are innocent, and as tame as lambs. Some females have a great number of these children. They have desires, like other people; and they fall in love with each other, and marry. Certainly *nobody else* would marry them.

It is said, that if two persons with a bronchocele<sup>a</sup> marry, their progeny generally have a goitre; and if their goiterous progeny marry any other persons with a bronchocele, then the third generation are sure to be idiots. Many persons assert this; but I do not know whether it is true; though I have endeavoured to ascertain it. There is a great relation between goitre and cretinism, no doubt; and what affects the thyroid gland, if it also affects the head and brain, may produce idiotism.

This is all that need be said about idiocy. It is more an object of curiosity, and medical jurisprudence, than of medical treatment; but it is very interesting, both in a physiological and a pathological point of view; and sometimes it is important in practice.

### SECTION III.—INSANITY.

*Various Terms employed.*—I will now proceed to the description of that kind of unsoundness of intellect which is called “insanity.”<sup>b</sup> Unsoundness of intellect comprises idiocy, imbecility, and insanity. Insanity is called “lunacy,”—“mental derangement,”—“mental aberration,”—“hallucination,”<sup>c</sup>—“alienation,”—“madness.”

*Definition.*—In describing mental deficiency, I stated that it was not every kind of mental deficiency that made an individual imbecile, or an idiot. The various feelings of the mind may be deficient, and very inconsiderable;—so inconsiderable as to be all but absent; and yet the individual may not be an idiot.<sup>d</sup> I stated that certain intellectual faculties (such as the faculty of music or calculation) might be deficient,—very deficient, and the person not be at all an idiot.<sup>d</sup> So aberration of mind, in insanity, does not exist merely because there is something wrong in the mind. There may be much very wrong in the mind, and yet the person not be at all *insane*;—just as there may be a great defect in the mind, and yet the person not be at all an *idiot*.

#### a. Varieties.

*Derangement of Volition and Sensation.*—In the first place, derangement of *volition* does not constitute insanity. A person may have palsy of motion; and yet he is not insane. He may wish to move his limbs, and be unable to do so; or he may wish to move them in one direction, and they may go in another, in a completely opposite direction; but he is not, on that account, insane. Neither does a want of the *external senses* constitute insanity, any more than it does *idiotism*. There may be merely palsy of the senses;—there may be a want of sensation from disease of the external organs of sense; and yet the person may be perfectly rational. Neither does it refer at all to the *knowing faculties*, such as music and calculation; which may be called “*internal senses*.” These may be more or less wrong; and

<sup>a</sup> From βρογχες, the windpipe; and κελη, a tumour.

<sup>b</sup> From “in,” not; and “sanus,” sound.

<sup>c</sup> From “hallucinator,” to err.

<sup>d</sup> See Pages 541 and 542.

yet the person not be insane. Just, therefore, as the want of effective volition,—just as the want of external sensation,—just as the want of any one of the knowing faculties, does not make a person an idiot; so a wrong operation of volition over the voluntary muscles,—an arm going one way, when the person wishes it to go in another,—is not insanity. A person labouring under chorea, or under tetanus, is not insane.

*False Perceptions.*—A wrong sensation does not constitute a person insane. He may have double vision;—he may see two fingers, when only one is held up; yet he is not on that account insane. Neither if a person see images,—figures,—spectres, is he on that account insane, if he do not believe that their existence is real. Some persons see objects which really do not exist;—images of objects which have no existence; and they *know* that such things do not exist; and therefore they are not insane. They are aware that there is a mere deception. Some see, in these circumstances, appearances of human beings, brutes, and various animals; but they are perfectly aware that it is entirely a morbid appearance.

One of the most remarkable instances of this description, occurred at Berlin; in the person of a bookseller named Nicolai. He saw an immense number of objects, —people and brutes,—at certain times; but he was aware that it was all the effect of morbid excitement. He had gone through considerable mental application; and, being aware that this was all a delusion, he was no more insane for seeing them, than a person would be for thinking he saw *two* fingers, when we held up but *one*.\*

\* I [Nicolai] saw, in a state of mind completely sound, and (after the first terror was over) with perfect calmness, for nearly two months, almost constantly and involuntarily, a vast number of human and other forms; and even heard their voices;—though all this was merely the consequence of a diseased state of the nerves, and an irregular circulation of the blood.

It being a matter of considerable importance, that an incident of this nature should be observed with the strictest attention, and related (together with all collateral circumstances) with the most conscientious fidelity, I shall not omit any thing of which I retain a clear recollection. The truth of what I am going to advance, will not require a further testimony; as Dr. Selle—who was my physician, and was daily informed by me of every trifling occurrence and change that happened—is still living; and will, by all who know him, be most readily admitted as an unobjectionable witness. During the ten latter months of the year 1790, I had experienced several melancholy incidents, which deeply affected me,—particularly in September; from which time I suffered an almost uninterrupted series of misfortunes, that afflicted me with the most poignant grief. I was accustomed to be bled twice a year; and this had been done once (on the ninth of July), but was omitted to be repeated at the end of the year 1790. I had, in 1783, been suddenly taken with a violent vertigo; which my physicians imputed to obstructions in the vessels of the abdomen, brought on by a sedentary life, and continual exertion of the mind. This indisposition was successfully removed, by means of a more strict diet. In the beginning, I had found the use of leeches applied to the arm particularly efficacious; and they were afterwards repeated two or three times annually, when I felt congestions in the head. The last leeches which had been put on, previously to the appearance of the phantasms of which I am about to speak, had been applied on the first of March, 1790; less blood had, consequently, been evacuated in 1790, than was usual with me; and, from September, I was constantly occupied in business that required the most unremitting exertions; and which was rendered still more perplexing by frequent interruptions.

I had, in January and February of the year 1791, the additional misfortune to experience several extremely unpleasant circumstances; which were followed, on the twenty-fourth of February, by a most violent alteration. My wife and another person came into my apartment in the morning, in order to console me; but I was too much agitated by a series of incidents, which had most powerfully affected my moral feelings, to be capable of attending to them. On a sudden I perceived, at about the distance of ten steps, a form like that of a deceased person. I pointed at it;—asking my wife if she did not see it. It was but natural that she should not see any thing: my question, therefore, alarmed her very much; and she sent immediately for a physician. The phantasm continued about eight minutes. I grew, at length, more calm; and, being extremely exhausted, fell into a restless sleep, which lasted about half an hour. The physician ascribed the apparition to a violent mental emotion, and hoped there would be no return; but the violent agitation of my mind had, in some way, disordered my nerves, and produced further consequences; which deserve a more minute description.

At four in the afternoon, the form which I had seen in the morning reappeared. I was by myself when this happened; and, being rather uneasy at the incident, went to my wife's apartment; but there, likewise, I was prevented by the apparition; which, however, at inter-

Brutus and Socrates are said to have seen,—the one the shade of Cæsar, and the other “the familiar spirit,” as he called it; but if neither the one nor the other believed this, they were not mad; or if they merely believed it in accordance with the belief of the day, then they were not mad; but if they knew better, and yet believed these things, then they were deranged. Hence there may be false percep-

vals disappeared; and always presented itself in a standing posture. About six o'clock, there appeared also several walking figures; which had no connection with the first.

After the first day, the form of the deceased person no more appeared; but its place was supplied by many other phantasms;—sometimes representing acquaintances, but mostly strangers; those whom I knew, were composed of living and deceased persons; but the number of the latter was comparatively small. I observed that the persons with whom I daily conversed, did not appear as phantasms;—the latter representing, chiefly, persons who lived at some distance.

These phantasms seemed equally clear and distinct at all times, and in all circumstances;—both when I was by myself, and when I was in company; and as well in the day as at night, and in my own house as well as abroad; they were, however, less frequent when I was in the house of a friend; and rarely appeared to me in the street. When I shut my eyes, these phantasms would sometimes vanish entirely; though there were instances when I beheld them with my eyes closed; yet, when they disappeared on such occasions, they generally returned when I opened my eyes. I sometimes conversed with my physician and my wife, of the phantasms which at the moment surrounded me. They appeared more frequently walking than at rest; nor were they constantly present. They frequently did not come for some time; but always reappeared for a longer or shorter period, either singly or in company;—the latter, however, being most frequently the case. I generally saw, however, forms of both sexes: but they usually seemed not to take the smallest notice of each other; moving as in a market-place, where all are eager to press through the crowd:—at times, however, they seemed to be transacting business with each other. I also saw, several times, people on horseback, dogs, and birds. All these phantasms appeared to me in their natural size, and as distinct as if alive;—exhibiting different shades of carnation in the uncovered parts, as well as in different colours and fashions in their dresses; though the colours seemed somewhat paler than in real nature. None of the figures appeared particularly terrible, comical, or disgusting;—most of them being of an indifferent shape, and some presenting a pleasing aspect. The longer these phantoms continued to visit me, the more frequently did they return; while, at the same time, they increased in number about four weeks after they had first appeared. I also began to hear them talk; the phantoms sometimes conversed among themselves; but more frequently addressed their discourse to me: their speeches were commonly short, and never of an unpleasant turn. At different times, there appeared to me both dear and sensible friends, of both sexes; whose addresses tended to appease my grief, which had not yet wholly subsided. Their consolatory speeches were, in general, addressed to me when alone. Sometimes, however, I was accosted by these consoling friends, while I was engaged in company; and, not unfrequently, while real friends were speaking to me. These consolatory addresses consisted, sometimes, of abrupt phrases; and, at other times, they were regularly executed.

Though my mind and body were in a tolerable state of sanity all this time, and these phantasms became so familiar to me, that they did not cause me the slightest uneasiness; and though I sometimes even amused myself with surveying them, and spoke jocularly of them to my physician and my wife, I yet did not neglect to use proper medicines;—especially when they began to haunt me the whole day, and even at night, as soon as I awaked.

At last, it was agreed that leeches should be again applied to me, as formerly; which was actually done on the twentieth of April, 1791, at eleven o'clock in the morning. No person was with me, except the surgeon; but during the operation, my chamber was crowded with human phantasms, of all descriptions. This continued uninterruptedly, till about half an hour after four o'clock;—just when my digestion commenced. I then perceived that they began to move more slowly; soon afterwards, their colour began to fade; and, at seven o'clock, they were entirely white. They moved very little, though the forms were as distinct as before,—growing, however, by degrees, more obscure; yet, not fewer in number,—as had generally been the case. The phantoms did not withdraw, nor did they vanish;—a circumstance which, previously to that time, had frequently happened. They now seemed to dissolve in the air; while fragments of some of them continued visible a considerable time. About eight o'clock, the room was entirely cleared of my fantastic visitors.

Since that time, I have felt, twice or three times, a sensation, as if these phantasms were going to reappear; without, however, actually seeing any thing. The same sensation surprised me, just before I drew up this account;—while I was examining some papers, relative to those apparitions, which I had drawn up in the year 1791.—“*Sketches of the Philosophy of Apparitions. By Samuel Hibbert, M.D.*” Chapters 1 and 5; Pages 4 to 8, and 41 to 44.

tions, and yet the individual may not be mad; but a person may be mad, and also have false perceptions. Many men, absolutely mad, think they see things which they do not; but many persons, without a false perception, see something that has no existence; but, knowing it has no existence, they are not deranged. Again: many persons, absolutely mad, never see any unnatural appearances whatever.

*Monomania.*—But in a great number of cases of insanity, we find an absurd belief; and this may refer to something past. There may be a fixed opinion, altogether absurd, upon matters that have passed; and there may be also an absurd opinion as to something *present*. For instance:—persons so affected, may see things which other people do not; and they may positively believe it. Insanity, therefore, may be an absurd belief, as to things present and things past; and thirdly, that absurd belief may refer to a mere abstract opinion. Persons may believe something so preposterous, that every body will consider them mad for so doing. A case is recorded of a butcher, who firmly believed he saw a leg of mutton hanging from his nose; and therefore he was certainly mad. Another is told of a baker, who fancied himself butter; and refused to go into the sunshine, lest he should melt. A painter thought he was soft;—he was so in mind. He thought he was so much putty; and that he could not walk without becoming compressed, like putty. Others have fancied themselves glass; and would not sit down lest they should crack.

*Case of Luther.*—Luther, although so able a man, was mad on some points. All people have their weak points; and he had his. He fancied the devil was in him;—as did also the Roman Catholics; and that he heard him speak. Luther's christian name was Martin; and in *Hudibras*<sup>a</sup> there is the following couplet upon it:—

“Did not the devil appear to Martin  
Luther, in Germany, for certain?”

It is stated, in a note to this passage, that “Luther, in his works, speaks of the devil appearing to him frequently; and how he used to drive him away by scoffing and jeering him; for Luther observes that the devil, being a proud spirit, cannot bear to be contemned and scoffed.” Luther used to talk to the devil; and the Popish writers not only believed that the devil was in him; but some of them affirm that he was begotten by an incubus (a kind of young devil); and that at length, when he died, the devil strangled him.<sup>b</sup>

Dr. Ferriar, of Manchester, had a patient of the same persuasion as Luther. He fancied he had swallowed the devil; and he would not discharge the contents of his alimentary canal, through a benevolent feeling;—lest he should let him loose into the world. I heard a gentleman speak of a man, who would not make water lest he should inundate the country. He thought the urine would come from him in such torrents, that the country would be washed away. A similar case to this was relieved by lighting a fire round the patient, and making him endeavour to put it out, lest the house should be burned down. Many persons fancy there are frogs, serpents, and snakes, within them; and one woman fancied there was a whole regiment of soldiers in her. One man, named Vicentinus, fancied he was too large to go through a door-way; and when he was pulled through he screamed, and fancied he was being lacerated, and actually died of fright.<sup>c</sup> Another woman, instead of fancying that she had a regiment of soldiers in her, fancied that she had a

<sup>a</sup> Part 2; Canto 3; Lines 155 and 156. The poet adds:—

“And would have gull’d him with a trick;  
But Martin was too politic.”

<sup>b</sup> We think that to be a lie which is fathered upon Luther;—to wit, that he knew the devil, and was very conversant with him, and had eaten many bushels of salt, and made jollie good cheere with him; and that he was confuted, in a disputation with a real divell, about the abolishing of private masse.—*Scot's “Discovery of Witchcraft.”*

<sup>c</sup> Quoted from Marcus Donatus, by Dr. A. T. Thomson; in a Lecture on Medical Jurisprudence, published in the “*Lancet*” for March 11, 1837. (No. 706; 1836-7, Volume 1, Page 841.)

monster in her genitals; and when she got rid of this idea, by the contrivance of her physician, she took another fancy; namely, that she had been dead, and had been sent back to the world without a heart, and was the most miserable of God's creatures. At the "Retreat," near York, one patient writes—"I have no soul. I have neither heart, liver, nor lungs; nor any thing at all in my body; nor a drop of blood in my veins. My bones are all burnt to a cinder. I have no brain; and my head is sometimes as hard as iron, and sometimes as soft as a pudding." One man, it appears, thought he had not got his own head. He is described in Moore's "Fudge Family at Paris."<sup>a</sup> He says:—

"Went to the mad-house.<sup>b</sup> Saw the man  
Who thinks,—poor wretch!—that (while the fiend  
Of discord here full riot ran)  
He, like the rest, was guillotined;

But that when, under Boney's reign,  
(A more discreet, though quite as strong one,)  
The heads were all restored again,  
He, in the scramble, got a *wrong one*.

Accordingly, he still cries out—  
'This strange head fits him most unpleasantly;'  
And always runs (poor dev'l!) about,  
Inquiring for his own incessantly."

Bishop Warburton, in a note to one of his works, speaks of a person who thought he was converted into a goose-pie; and Dr. Arnold saw a man who fancied himself in the family-way. Pope, in his "Rape of the Lock"<sup>a</sup> describes many of these fancies. He says, in giving a sketch of hypochondriacal persons,<sup>c</sup>—

"Unnumber'd throngs on every side are seen,  
Of bodies changed to various forms by Spleen.  
Here living tea-pots stand; one arm held out,  
One bent;—the handle this, and that the spout.  
A pipkin there, like Homer's tripod, walks;—  
Here sighs a jar, and there a goose-pie talks."

A man in the University of Oxford, fancied himself dead; and lay in bed, waiting for the tolling of the bell; but, not hearing it at the time he expected, he fell into a violent passion, and ran and tolled it himself. He was then spoken to, on the absurdity of a dead man tolling his own bell; and it is said that he returned, and was afterwards sound in his intellect. However, he must have been pretty nearly in his senses at this time;—he must have been ready for sanity; or such a change would not have been effected by a mere mental cause, like this.

Simon Browne, a dissenting minister,<sup>d</sup> wrote the best answer<sup>e</sup> to Toland's work, entitled "Christianity as Old as the Creation;" but, notwithstanding the great powers of mind displayed in this work, he thought that, by the judgment of God, his rational soul had perished; and that he had only brute life; and he absolutely inserted this in the dedication of his work to the Queen.<sup>h</sup> This dedication, however, was afterwards suppressed.<sup>i</sup>

<sup>h</sup> Caroline, consort of George the Second.

<sup>i</sup> Madam — Of all the extraordinary things that have been tendered to your royal hands, since your first arrival in Britain, it may be boldly said what now bespeaks your Majesty's acceptance is the chief. Not in itself, indeed; it is a trifle unworthy your exalted rank, and what will hardly prove an entertaining amusement to one of your Majesty's deep penetration, exact judgment, and fine taste; but on account of the author, who is the first being of

Baron Swedenborg, a very learned and able man, thought that he had communications with the Almighty for thirty years; and that he had been shown, by the Almighty, the mysteries of nature. Many think he was right; but no one could have that idea without some insanity. As some believe this, I mention it as an instance (adduced by others) of partial insanity. It is similar to the case of the celebrated Pascal; who, while he was working the problem of the cycloid curve, with great powers of intellect, was tied (by his own desire) in his chair; lest he should fall into a yawning gulf before him. He laboured under this partial insanity, while his powers of mind were otherwise as strong, and he was as much in his senses, as other people who have no madness whatever. One patient in the "Retreat" near York, wrote the following verses on the patient who described himself as having neither heart, liver, brain, nor any thing else.<sup>a</sup>

"A miracle, my friends, come view!—  
A man (admit his own words true)  
Who lives without a soul;  
Nor liver, lungs, nor heart has he;  
Yet sometimes can as cheerful be  
As if he had the whole.

His head (take his own words along)  
Now hard as iron, yet ere long  
Is soft as any jelly;  
All burnt his sinews and his lungs;  
Of his complaints not fifty tongues  
Could find enough to tell ye.

the kind, and yet without a name. He was once a man, and of some little name; but of no worth;—as his present unparalleled case makes but too manifest; for, by the immediate hand of an avenging God, his very thinking substance has, for more than seven years, been continually wasting away, till it is wholly perished out of him,—if it be not utterly come to nothing. None,—no, not the least remembrance of its very ruins remains; not the shadow of an idea is left; nor any sense—so much as one single one, perfect or imperfect, whole or diminished—ever did appear to a mind within him, or was perceived by it. Such a present from such a thing, however worthless in itself, may not be wholly unacceptable to your majesty;—the author being such as history cannot parallel; and if the fact—which is real, and no fiction or wrong conceit—obtains credit, it must be recorded as the most memorable, and, indeed, astonishing event in the reign of George the Second;—that a tract, composed by such a thing, was presented to the illustrious Caroline; "*his royal consort*" need not be added: fame, if I am not misinformed, will tell that with pleasure to all succeeding times.

He has been informed, that your majesty's piety is as genuine and eminent, as your excellent qualities are great and conspicuous. This can, indeed, be truly known to the great Searcher of Hearts only. He alone, who can look into them, can discern if they are sincere, and the main intention corresponds with the appearance; and your majesty cannot take it amiss, if such an author hints, that this secret approbation is of infinitely greater value than the commendation of men; who may be easily mistaken, and are too apt to flatter their superiors. But, if he has been told the truth, such a case as his will certainly strike your majesty with astonishment; and may raise that commiseration in your royal breast, which he has in vain endeavoured to excite in those of his friends; who, by the most unreasonable and ill-founded conceit in the world, have imagined that a thinking being could, for seven years together, live a stranger to its own powers, exercises, operations, and state; and to what the great God has been doing in it, and to it. If your majesty, in your most retired address to the "King of kings," should think of so singular a case, you may perhaps make it your devout request, that the reign of your beloved sovereign and consort may be renowned to all posterity, by the recovery of a soul now in the utmost ruin,—the restoration of one utterly lost, at present, amongst men. And should this case affect your royal breast, you will recommend it to the piety and prayers of all the truly devout, who have the honour to be known to your majesty: many such doubtless there are, though courts are not usually the places where the devout resort, or where devotion reigns; and it is not improbable, that multitudes of the pious throughout the land may take a case to heart, that under your majesty's patronage comes thus recommended.

Could such a favour as this restoration be obtained from Heaven by the prayers of your majesty, with what transport of gratitude would the recovered being throw himself at your feet; and, adoring the divine power and grace, profess himself, Madam, your Majesty's most obliged and dutiful servant, Simon Browne.—*Dr. Hawkesworth's "Adventurer,"* No. 88.

<sup>a</sup> See Page 550.

Yet he who paints his likeness here,  
 Has just as much himself to fear  
 He's wrong from top to toe.  
 Ah, friends, pray help us, if you can;  
 And make us each again a man;  
 That we from hence may go!"<sup>a</sup>

In insanity, therefore, we see that *all* the faculties are not deranged. There may be merely an absurd belief upon some one point; and the patient may otherwise be in his senses. Many, indeed, who are deranged, will read and understand what they read. They will paint, exhibit mechanical contrivances, work, and talk rationally on many subjects;—nay, some will show extreme sagacity in accomplishing their mad purposes, in concealing their mad impressions, and convincing others of the truth of their mad notions. In a case tried before Lord Mansfield, the patient<sup>b</sup> was so clever, that he evaded all the questions put to him; and seemed to every body perfectly sane. Dr. Battie, however, came into court; and, knowing the point of the man's derangement, asked what had become of the princess, with whom he had been in the habit of corresponding in cherry-juice? Instantly the man forgot himself; and said it was true he had been confined in a castle; where, for want of pen and ink, he had written his letters in cherry-juice, and thrown them into the stream below, where the princess had received them in a boat.<sup>c</sup>

*Increased Power of some Mental Faculties.*—This, however, is not all; for some persons, in insanity, have some of their mental faculties increased. Dr. Rush says, that he had a deranged female patient, who composed and sang hymns and songs delightfully; and yet she had never shown any talent for either music or poetry before. There was excitement of one part of the brain, while another part was going wrong. He knew two cases where, in insanity, a great talent was shown for drawing. Dr. Willis had a patient who, in the paroxysms of insanity, and then only, remembered long passages of Latin authors, and took extreme delight in repeating them; Dr. Cox mentions a musician, who talked madly on all subjects but music; and his talent for that appeared increased. His performances on the violin were strikingly singular and original. Dr. Rush mentions the case of a gentleman who was deranged; but who often delighted and astonished the rest of the patients, and the officers of the institution, by his displays of oratory when preaching. Pinel, the French physician, mentions the case of a man, who was very vulgar at other times; but who, in his paroxysms of insanity, while standing upon a table in the hospital, discoursed very eloquently upon the revolution; and with the dignity and propriety of language of the best educated man.

*Similar Occurrences in Fever.*—Circumstances similar to these, have been seen in fever. When the brain is under the excitement of fever, a person who has shown but little talent for singing before, may sing very correctly; and sometimes, although an individual may be delirious, yet he will speak very eloquently upon certain subjects. This state, however, does not last long.

*General Insanity.*—Some patients are not so happily circumstanced as those we have mentioned; but, in their insanity, are wrong upon *all* points. Persons may be deranged on only one or more points, while the rest of the faculties are *sound*; or they may be deranged on one or more points, while one faculty (or more) will

<sup>a</sup> See "Remarks on Mental Affections," by Thomas Bakewell; published in the "Imperial Magazine," Volume 4, Column 1002. (No. 46; November, 1822.) Mr. Bakewell is the proprietor of a well-conducted Lunatic-Asylum, called "Spring-Vale," near Stone.

<sup>b</sup> Mr. Wood, a merchant of Philpot Lane, who indicted Dr. Munro for confining him in a mad-house, while (as he alleged) perfectly sane.

<sup>c</sup> This trial having taken place in Westminster, he commenced another action in the city of London; and, on this occasion, no effort could induce him to expose his insanity; so that he was defeated only by bringing against him the evidence taken at Westminster.—"*Inquiries concerning the Intellectual Powers.* By John Abercrombie, M.D." Part 3; Section 4; Division 2; Subdivision 3. (Ninth Edition; Pages 324 and 325.) The case is detailed at length in "Elements of Medical Jurisprudence; by Theodric Romeyn Beck, M.D. Edited by John Darwall, M.D." Chapter 12; Section 2.

be increased; but patients may be wrong on *all* points. In the latter case, they will ramble from one point to another, display great inconsistency, and exhibit a wild association of ideas. They will be incapable of fixing their attention sufficiently to speak correctly, or to read. So wrong are they that, very likely, they do not recognize those with whom they were formerly intimate; or, if they do recognize them, it is in a very strange manner; and they have generally a very imperfect memory altogether; most likely, have false ideas of nearly every thing with which their memory is charged. Their absurd opinions, too, are general. Perhaps they reason very incorrectly on every thing; or they probably make no attempt at reasoning at all. In partial insanity, which is called "monomania,"<sup>a</sup>—insanity on a single point, when they do not reason correctly from a starting point, it is to be remembered that the starting point itself is partly incorrect. But, in intense insanity, they do not make an attempt to reason at all; or they reason in the most incorrect manner.

*Influence of the Propensities and Sentiments.*—So much with respect to the intellectual faculties. But in insanity the *propensities* and *sentiments* are frequently disturbed. Some are so far disturbed as to be superstitious; some, again, are very respectful; some, again, are very impious. There was one madman who cursed God for his creation: and especially for having given him a human form; and he wished to go to hell, to avoid the disgrace of associating with the Deity. A person saying to him it was a bad day, he replied—"Did you ever know God make a good one?" Some are thievish: some are modest; some are very silly; some are lascivious; some are depraved in their sexual feelings; some are very cheerful; some are melancholy; some are fearful. Sometimes violence and tranquillity, or melancholy, alternate. Shakspeare describes these changes:—

..... "This is mere madness!  
And thus, awhile, the fit will work on him,  
Anon, as patient as the female dove,  
When that her golden couplets are disclosed,<sup>b</sup>  
His silence will sit drooping."<sup>c</sup>

*Identity of Mania and Melancholia.*—There is no real difference between "mania" and "melancholia." The latter term is employed by many writers to signify madness connected with great depression of spirits; and it is applied by Pinel to *partial* insanity;—that is, to designate monomania. But this is improper. There is no essential difference between mania<sup>d</sup> and melancholia.<sup>e</sup> One faculty of the mind is disturbed in one case; and one in another. One person may be gloomy, and another cheerful; but the latter is just as mad as the former. A person may be gloomy to-day, and cheerful to-morrow.

*Influence of the Feelings.*—In insanity, every feeling of the mind may, in its turn, be excessive; or every feeling may be defective, or at least overcome by other feelings; and every feeling may likewise be depraved. In consequence of the varied state of feeling in insanity, we have various physiognomies. One madman has the physiognomy of pride;—holding up his head as high as he can, and looking with scorn on those around him. Others have the physiognomy of suspicion—a hanging down of the head; in others we see the physiognomy of rage—a frowning of the eyebrows, and a derangement of the features. The passion displayed in insanity, varies according to the state of the feelings.

*The Feelings only affected: Destructiveness.*—In some instances of insanity, the *feelings* only are affected. There is no aberration of intellect; but it is a disease of some of the feelings. There can be no question that some have an irresistible desire to commit murder. They are sane in every point but that; but they are irresistibly compelled to commit murder; and the moment they have committed it, they have confessed it, and expressed the greatest regret. Many have felt the fit of desire coming upon them; and have entreated their friends to confine them, to prevent them from doing it. This derangement of the feelings will sometimes

<sup>a</sup> From *μνος*, *one*; and "mania," *madness*. (See Page 549.)

<sup>b</sup> Hatched.

<sup>c</sup> From *μαινομαι*, *to rage*.

<sup>d</sup> "Hamlet," Act 5; Scene 2.

<sup>e</sup> From *μελας*, *black*; and *χολη*, *bile*.

take *one* turn, and sometimes *another*. There can be no doubt that some have felt an impulse to destroy in a particular manner;—by burning. Some have felt an impulse to destroy *themselves*; and others, not only to murder individuals, but to murder *particular kinds* of individuals;—to murder their *children*.

When I was at the University of Cambridge, there was a person who was said to have attempted, three times, to set the college on fire; and at last he was tried for it; but, as he was acquitted, I suppose he had not made the attempt. It was ascertained that, when he was young, he had attempted to drown a child; yet nobody ever suspected him of being mad.

The murderer of Mr. and Mrs. Bonner, at Chiselmurst, (in Kent,) was a footman in the family; and, one night, he left his room, went up stairs with a poker to the apartment of his master and mistress, and beat their brains out. He was asked his reason; but he could give none. He said that he had always been treated by them with the greatest kindness; and all he knew was, that he felt suddenly, in the night, a desire to kill them; and he supposed the devil had prompted him to the act. No other sign of insanity was detected in him; and as, at that time, it was not supposed that such an occurrence could arise from insanity, without other proofs of insanity being evident, he was hanged.

Gall mentions the case of a person at Vienna, who went to witness an execution; and was seized with a propensity to kill. At the same time, he had a clear consciousness of his situation. He expressed the greatest aversion to such a crime. He wept bitterly, struck his head, wrung his hands, and cried to his friends to take care and fly away. He felt the inclination; he regretted it; and entreated every one to prevent it, by putting him in prison.

Pinel mentions the case of a man, who exhibited no unsoundness of intellect; but who confessed that he had a propensity to murder, which was quite involuntary; and his wife, notwithstanding his tenderness for her (which was real), was near being murdered;—he having had only time to warn her to fly. In the interval he expressed the same remorse; felt disgusted with life; and attempted, several times, to put an end to his existence. In a work by Mr. Hill, we read of a man who was tried at Norwich, in 1805, for wounding his wife, and cutting his child's throat. He had been known to tie himself with ropes for a week, to prevent him from doing mischief to others. One of the members of a family in London, whose maid-servant was executed for attempting to poison the whole family with arsenic, is said to have used these words:—"Do, for God's sake, get me confined; for, if I am at liberty, I shall destroy myself and wife. I shall do it unless all means of destruction are removed; and therefore do, good friend, have me put under restraint. Something from above tells me I must do it; and I shall." Arsenic was put into a pudding; and the maid-servant was executed for it; but many persons were perfectly convinced of her innocence.

Respecting the disposition to destroy by fire, Gall mentions that he saw a person in prison at Fribourg, who had set fire to his house four times in succession; and who, after he had set fire to it, tried to put it out. Once he seized his child, lest it should be burned. The moment he had set his house on fire, he was contented; the orgasm was over; and he was as anxious as any one to see it put out.

*Propensity to Steal.*—Some have an irresistible desire to steal; without any other mark of insanity. Gall says that the first king of Sweden was always stealing trifles. Instances are mentioned of a German, who was constantly pilfering; and of another who had the desire entered the army;—hoping that the severe discipline there would restrain him; but he gave way to the desire even there, and was very near being hung. He then became a friar, with the same hope; but he still felt the same desire, and carried all the things he could to the cell; but, as he could only get trifles, he was not noticed; and he went on with his propensity. Gall also mentions that a person at Vienna, in the habit of stealing, hired a lodging to deposit his thefts; and, when he had got a stock, he sold them. He only stole household matters. The wife of a celebrated physician, at Leyden, never went into a shop to buy any thing without stealing; and a countess at Frankfort had the same

propensity. Another lady, notwithstanding all the care with which she was brought up, had the same desire to pilfer. It is related of a physician, that his wife was always obliged to examine his pockets in the evening, and restore the things she found there to his patients. He always took something, as well as his fee. Meritz speaks of a criminal who, at the moment he was about to be executed, stole the confessor's snuff-box. Dr. Burner, who was one of the physicians to the king of Bavaria, speaks of a person whom he knew very well, who enjoyed abundance, and had been well educated; but who, notwithstanding, was always stealing; and was made a soldier by his father, and at last got hanged. The son of a celebrated and learned man, himself very clever, and respectably connected in every respect, could not resist this propensity; and I could go on mentioning instances without end, of individuals who apparently did this from insanity;—not from any criminal motives, but absolutely from a blind desire too strong for them to resist.

*Inordinate Sexual Desire.*—The sexual desire has been so inordinately strong, in some people, that it has been said that a criminal, going to execution for a rape, has been anxious to repeat the crime as he was proceeding to the gallows. I know it is so with respect to an irregular mode of gratification;—masturbation. I was told, by a medical man, of an individual who was rather idiotic; and who had the desire so strong, that he would entreat his family to run out of the room. He could not resist the impulse to gratification; though he cried, and lamented its power over him.

*Two-fold Definition of Insanity.*—The definition of insanity, then, is two-fold. It may be stated to be—"an aberration of any mental power from a healthy state; with an inability on the part of the individual to discern its unhealthiness;" because, if an individual be aware of the absurdity and non-reality of what he fancies, he is not mad. If a person see the devil in the middle of the day, and is sure it is not the devil at all, of course he is not mad; but if the man see it, and believe it, and endeavour to make others believe it is a reality,—provided he has been better educated,—he must be mad. But this is not the whole of the disease; and not the form in which it will sometimes appear; and therefore we must include in the definition—"without an ability, on the part of the patient, to discover that it is an unhealthy state, or to resist it." If an individual have feelings so strong that he cannot control them, he is not an accountable being;—he is insane. This is the definition of Spurzheim; and it is the best I have seen. I have met with no other that satisfies me. It is a *general* definition; and it includes all the forms we can give, in a *minute* definition of insanity. I have reflected much upon it; and think it will apply to every case.

*Intellectual Aberration as to Facts.*—With respect to the first part of the definition,—that in which is mentioned an intellectual aberration,—it may relate to a matter of external sense, or to a fact which may be present or past; and in that case there can be no doubt of a person's insanity. If a person firmly believe something to be actually a fact,—to be present,—to be existent, which we know is not the case, and which all the world knows is not the case (as, for example, that a leg of mutton is hanging to his nose\*);—then we know he must be mad. If the aberration refer to a matter of fact that is present, we may declare him to be mad; or if it refer to something which is past, on which we are equally certain, and on which he has had an opportunity of being well informed when in his senses, it is fair to conclude that he is mad. If he be certain that he lived two hundred years ago, then there can be no doubt that he is mad.

*Intellectual Aberration as to Opinions.*—Supposing, however, that it does not refer to a fact past or present, but to a mere opinion, then there may be considerable difficulty. In order to constitute him mad, it ought not to be a subject on which there is some difference of sentiment among other persons; but an opinion palpably absurd to all other people in the situation of life, or superior to him. If we did not make an allowance for education, for country, and for external circumstances, every sect in religion (for example) might consider the votaries of another sect to be mad.

\* See Page 549.

Every Trinitarian would consider a Unitarian to be mad; and every Unitarian would consider a Trinitarian to be mad. Quakers would consider Jumpers to be mad; and Jumpers would consider Quakers to be mad. Every allowance, therefore, is to be made, in a matter of opinion, for difference of education and difference of situation.

The notions entertained by one nation altogether, would be considered perfectly absurd by another nation; and therefore it must be an opinion upon matters, on which all persons of the same country, age, situation, and education, will allow such an opinion to be positively absurd. If, in this country, a woman were to insist on burning herself to death after the decease of her husband, we should consider it insanity; but in India it is *not* insanity; because the people there have been educated in the belief of its propriety. It was mentioned in the House of Commons by Mr. Buxton, in 1821, that in the Presidency of Fort William, two thousand three hundred and sixty-six widows destroyed themselves in the previous four years; and some of these were only twelve or thirteen years of age. One was only eight; and one only eleven was so obstinate, when she was not allowed to burn herself to death, that she fasted from food for four or five days; and, although the local authorities prevented her from immolating herself on her husband's grave, she saved some of his bones;—in order that, when the first opportunity occurred, she might then destroy herself. Now such an act as this would be considered, in our country, as downright insanity;—it could scarcely arise from any thing else.

*Necessity for well-informed Juries.*—The ignorant have often imputed insanity to philosophers. Democritus was pronounced mad, by the common people, because he dissected a body, in order to investigate the causes of insanity; but Hippocrates told the people that they were mad, and not Democritus. In a case of this description, a jury who were equally well-informed persons with the philosopher, would have been the only people capable of determining the question. If we empanel a jury to determine the madness of a person, they should be equal or superior to him. If we select persons inferior to the person supposed to be mad, they (through their ignorance) may conceive him to be mad, when he is only a man of knowledge superior to themselves. If the matter, therefore, refer merely to *opinion*, there may be considerable difficulty as to the sanity or insanity of the individual; and no one who is not equal to the individual, or even superior to him, is capable of judging; and every allowance should be made for education, and for all external circumstances. If we take these precautions, we may disregard the complaint,—that “the madman was as much in his senses, as the rest of the world; but the majority was against him, and therefore he was placed in custody.”

*Diagnosis between the Culprit and the Madman.*—Supposing, however, that it is another form of insanity; a propensity; and a propensity to murder; which propensity the patient cannot resist. Here the great difficulty is to ascertain whether this state is real or not;—whether (in case an act of murder has been committed) the individual could not have resisted the propensity;—whether he has been giving way to some vile feeling, or has been the victim of an irresistible passion. Now, in pronouncing a person who has committed a crime to be insane,—as having been unable to resist the temptation,—we must ascertain first whether there has been any motive or not. If any motive can be discovered, then we may be justified in saying that the individual is a culprit,—is not mad. There should, in the first place, have been an evident reason for it. Generally, however, where there is some irresistible feeling, there is, at the same time, some wrong notion. When persons have committed murder, from an instantaneous desire to destroy, generally (though by no means always) they had, at the same time, some wrong notion;—some imagination that it was a voice from Heaven that called them to commit the deed. Hence we have less difficulty than we otherwise should have. In many of these cases, where there has been no motive, the patient himself, as soon as the deed has been over, has actually declared that he had no motive, and has expressed the greatest remorse for what has been done. On other occasions, he has laughed at the deed;—considered it a matter of indifference;—not concealed it, but given himself up to justice. In other cases, before the deed has been done,

patients have requested to be confined, and thus prevented from doing what their feelings prompted.

*Indications afforded by the Shape of the Head.*—To those who have paid any attention to phrenology,<sup>a</sup> not only is this not wonderful, but considerable assistance may be derived from examining the shape of the head. The shape of the head does not show a man to be mad; for a man with a head of *one* shape may become insane, as well as a man with a head of *another* shape. A stomach of *one* shape or size will be subject to dyspepsia, the same as a stomach of *another* shape or size. It is absurd to suppose that, in insanity, there must be a particular shape of the head; but it is an unquestionable fact, that if a person have any one peculiar feeling of the mind, (which feeling phrenologists believe to be situated in a particular part of the brain,) and the correspondent part of the head be correspondently largely developed; that strong feeling will take the lead of the other feelings. Putting phrenology out of the question, whatever feeling or passion is remarkably predominant in an individual,—so as to take the lead,—if the other proportions of the brain be too small, such an individual is likely to go mad. Now if it be a fact that the brain, in different parts, corresponds with the natural intensity of the different feelings, then that part of the head may be expected (in general) to be proportionately large; and if it be said of an individual supposed to be mad, that he is the victim of a particular feeling, any one who attended to phrenology would certainly examine the head, and see whether there was a large development, corresponding with the passion which appeared irresistible; and if he found such a correspondence, that would be an additional reason for inclining to the belief, that the individual had been the victim of a feeling that was irresistible.

*Case of Bellingham.*—This was shown strikingly in the case of Bellingham, who murdered Mr. Perceval. Bellingham was a man of weak intellect; and we see, from a cast of his head, that the anterior parts of the head were miserably developed; whereas the lateral parts (posterior and anterior) were largely developed: so that the man's passions were evidently much too strong for him to resist; and the passions particularly developed in him, were pride and destructiveness. That man was executed, because there was no proof at all that he was insane; but any one, on looking at his head, would incline to a favourable opinion; and though he would not set him at large, to do such mischief again, yet he would not deprive him of life. There is a large development of pride and destructiveness; and that part of the brain, being large, has gained an ascendancy over the rest; and has been liable to excitement. In a great number of cases of insanity, the character of the individual corresponds with the form of the head; and when the question is, whether the propensity to the deed which has been done was irresistible, or whether the patient could have controlled it, we may find it of great service to examine the head. If we have *other* reasons to believe that the deed has been done irresistibly, a peculiar development of the head (if it exist) is an *additional* reason. The shape of the head is not to be depended upon *solely*; but to be taken into consideration, in conjunction with *other* circumstances.

*Has there been Previous Injury of the Head, or Apoplexy?*—Another circumstance that would render the existence of insanity probable, would be the previous receipt of an injury of the head. If a person have once sustained such an injury, of course the head is very likely to go wrong. If we have no ostensible reason for the act, but (on the contrary) have reason to believe that the man was the victim of irresistible impulse: and if we know that he has had an injury of the head formerly; we should then be doubly inclined to the opinion of his being insane, and should urge the judges to show mercy, on account of the injury in question. Another thing to be considered is, whether he has had a fit of apoplexy or of paralysis; for if he have, then the head might be supposed to be going wrong, when the man committed the deed.

*Has Insanity existed in his Family?*—Another circumstance will be the ex-

<sup>a</sup> From φῆνν, *the mind*; and λόγος, *discourse*.

istence of insanity in his family. If an individual do a criminal act, and we have strong reason to believe that he did it through insanity,—although he may never have had an hallucination; yet, if we find insanity in his family, we may conclude the insanity has descended to him. Nay, if we find that *no* injury of the head has ever existed, and there has been *no* insanity in the family; yet if this man was insane on a former occasion, then we have strong reason to believe, that this very act was only the recurrence of insanity; even though the previous attack may have been short,—though the person's peculiarity of mind have merely amounted to great eccentricity.

These are circumstances that will assist our judgment, when a person has shown no hallucination at all; but merely done a deed, which we suspect must be the result of insanity. In the first place, there should be no motive for the deed. Secondly, it is to be considered whether, at the moment he did it, the person *confessed* that he had no motive; and gave himself up to justice. Thirdly, consider whether or not the patient was aware that he had done any great injury. In the next place, consider whether the propensity to commit the act has come on in a paroxysm; and the patient has been aware of it, and wished to be confined. Then, if there be an agreement of the head with the passion; if there be insanity in the family; or the individual have been previously insane; or there have been other diseases of the nervous system (such as apoplexy or paralysis);—in these circumstances, the individual is “mad,” in the common acceptance of the term; though he is not mad *legally*. In many of these cases, however, there is not such great difficulty; because, some wrong idea has generally been observed.

*Many Insane Persons not Legally Mad.*—Although it is quite necessary to prove that a man has been wrong in some of his notions (either relating to facts present or past); or in some matters of opinion;—although it is necessary to prove that he is absolutely deranged on that one point, or that he is the victim of some one irresistible feeling, before we can say, *legally* speaking, that he is mad; yet *pathologically* we may say, that a great number of people who are at large, are insane. A great number of people at large have any thing but a healthy state of the brain. They have one feeling too strong, or they have a ridiculous notion upon some point; but it is so slight, that it does not disqualify a person for carrying on the affairs of life; and therefore it is only said, that such an one is “a strange fellow,” or “an odd fellow;” and so he passes. Speaking *pathologically*, then, a large number of people, who go about, are more or less “cracked;” but *legally* speaking, in order to be accounted mad, a man ought certainly to have a mental power in a state of aberration from a healthy state, to such a degree as to disqualify him from conducting the ordinary business of life; or should be the victim of some strong feeling, which leads to the injury of others, or of himself.

*Hypochondriasis.*—If it be a mere matter of *opinion* on which a person is, pathologically speaking, mad;—as, for instance, that an individual has an unfounded fear of disease, and of death,—we call it merely “hypochondriasis;” and it does not justify us in calling him “mad.” If a man who has nothing the matter with him, is satisfied he is in a consumption, because he coughs twice a day; and, because he spits a drachm of mucus in the twenty-four hours, is satisfied that his lungs are full of abscesses, this is a morbid feeling; but as it would not lead to a criminal act, or to any act which is dangerous to others, we do not say he is “mad.” We only call the feeling “hypochondriacal;” but the *nature* of that feeling is exactly the same. Many such persons act, on different occasions, very absurdly. Some will not dress as other people dress; some will not eat as other people eat; and they will do a number of things more or less extravagant; but, as the *degree* of extravagance is less, and as they do no act which is injurious to others, we do not call them “madmen.” They merely pass as “*eccentric* individuals;” but some one in the family will carry his eccentricity to a higher pitch; and then it is necessary to confine him. It is absolute madness. Suppose a man squanders all his money away;—not for the gratification of a particular feeling, but in a way which is quite contrary to what all other people do; or suppose he in-

flicts punishment upon himself, and attempts to murder himself or others, or commit depredations on the property of others;—we are not justified in saying, *legally*, that he is mad; although, *medically*, we are quite satisfied that he is in an unsound state.

*Suicidal Mania.*—But although, when the person suspected of insanity is *alive*, it is necessary to use all these precautions; yet, when the person is *dead*, we are allowed to incline to this opinion on much more general grounds. When a person is alive, of course it is a serious thing to treat him as a madman; and, whatever his eccentricities may be, we are not allowed to say that he is legally mad, unless perfectly satisfied that he does things not simply *injurious*, but *criminally* injurious to himself or others. If he be guilty of such acts, we may be justified in saying he is mad. But if he has destroyed himself, then, on the slightest grounds whatever,—if he have merely said a word or two of nonsense, we are allowed to say that he is legally mad. When a person has committed suicide (which act cannot be committed again), the least probability of mental derangement is admitted by law. Where a person is alive, it is mercy which induces the law to compel us to give evident proof, before a man is pronounced insane; because it would be cruel to confine him without: but when a person is dead, it is desirable to prevent his being treated as a self-murderer; and it is a mercy to make it appear, as much as possible, the result of a morbid state of mind. There can be no doubt, in my opinion, that many criminals are not called “mad,” who really are so. I have no doubt that thousands, whose crimes were the result of insanity,—who were not responsible agents, have been executed unjustly; and that thousands more will be executed.

*Difficulty of Detecting the Hallucination.*—There may be extreme difficulty, sometimes, in ascertaining that an individual has any absurd belief at all; and there is a difficulty on the other side of the question, respecting this absurd belief. Occasionally, it is almost impossible to ascertain whether a man is mad;—owing to the cunning of madmen. When persons are mad, they frequently have sufficient cunning to deceive any one who is not thoroughly acquainted, not only with the habits of madmen in general, but with the belief of the particular individual. It requires very great skill, sometimes, to bring a person to speak on the point on which he is absurd.

I have mentioned the case of a man, who underwent a most severe examination without exposing his complaint; until asked by Dr. Battie (who knew the point on which he was insane) what had become of the princess, with whom he had corresponded in cherry-juice.<sup>a</sup> We have another instance too striking to be omitted:—“I well remember,” says Lord Erskine,<sup>b</sup> “that since the noble and learned judge<sup>c</sup> has presided in this court,<sup>d</sup> I examined, for the greater part of a day, in this very place, an unfortunate gentleman, who had indicted a most affectionate brother, together with a keeper of a madhouse at Hoxton, for having imprisoned him as a lunatic; while, according to his evidence, he was in his perfect senses. I was, unfortunately, not instructed in what his lunacy consisted; although my instructions left me no doubt of the *fact*; but, not having the clue, he completely foiled me in every attempt to expose his infirmity. You may believe that I left no means unemployed, which long experience dictated; but without the smallest effect. The day was wasted; and the prosecutor, by the most affecting history of unmerited suffering, appeared to the judges and jury, and to a humane English audience, as the victim of the most wanton and barbarous oppression. At last Dr. Sims, who had been prevented by business from an earlier attendance, came into court. From him I soon learned, that the very man whom I had been above an hour examining, with every possible effort which counsel are so much in the habit of exerting, believed himself to be the Lord and Saviour of mankind;—not merely at the time of his confinement, (which was alone necessary for my defence,) but during the

<sup>a</sup> See Page 552.

<sup>b</sup> On the trial of James Hatfield, for shooting at George the Third.

<sup>c</sup> Lord Mansfield.

<sup>d</sup> The Court of King's (now Queen's) Bench.

whole time that he had been triumphing over every attempt to surprise him in the concealment of his disease. I then affected to lament the indecency of my ignorant examination; when he expressed his forgiveness; and said, with the utmost gravity and emphasis, in the face of the whole court,—‘I am the Christ;’ and so the cause ended.”<sup>a</sup>

We see, therefore, the extreme difficulty which we may sometimes meet with, in detecting the madness of an individual; that a very minute inquiry is necessary; and that sometimes no minuteness of inquiry will do, unless we are informed of the particular point on which the individual is deranged.

### *b. Physical Signs of Insanity, and its Progress.*

Besides the varieties of insanity,—the variety of absurd notions, the variety of degree, and the absolute extent of this absurdity, (the person being absurd on *one* notion, or on *every* thing; from having little intellectual power left, or very little perception on a point;—)besides the variety of the native characters of individuals, independent of their sanity or insanity; and the variety that must exist as to the *derangement* of feeling, as well as an *excess* or *defect* of feeling;—besides all these, there are many other circumstances which occur in insanity.

*Physical Signs.*—The head, for example, is frequently hot (both in the various paroxysms, and at the commencement of the disease;) frequently the urine is red; the pulse is quick, full and firm; the eyes and cheeks are red; in fact, there is more or less of an inflammatory condition of the head. Then there are pains, and all kinds of odd sensations in the head;—cracking, bursting, twitching pains of every description. Insane persons speak of flashes of light, of double vision, of noises in their ears; and nothing is more common than deafness, which is the usual disturbance of the external senses in madmen. Sometimes there is a depravation of smell. Patients will fancy there is some intolerable stench around them, and will speak out of their nose. I believe they are generally very fond of snuff. Occasionally, too, there is a great resistance to external cold; but this is by no means universal; for many insane persons, through this notion, have been left to themselves; their extremities have mortified; and they have died. Now and then, however, there has been observed an extreme insensibility to cold; so that they have exposed themselves to frost and snow, without suffering from it in the least. There is apparently a great insensibility even of the external senses; but this principally arises from the abstraction of mind which, in general, is kept up within; so that the patient does not attend to what goes on around. On the other hand, however, extreme *sensibility* has very often been noticed in the disease. Sometimes we observe a sort of stupor; and this is not constant, but comes on occasionally. There are often various other diseases of the brain; such as epilepsy, paralysis, hysteria and catalepsy. The integuments of the head, especially the posterior, superior parts, are often loose and spongy; so that if the scalp be gathered up, it will be found fuller than usual, and loose.

The breath is very offensive; and some say there is a peculiar smell of the body;—so that we can smell a madman. Some, however, think it very hard that a person should be called “mad,” because he does not smell like a gentleman. The tongue is very frequently foul, and the mouth is filled with a viscid mucus; so that madmen are constantly endeavouring to spit it out. I presume there is sometimes a depraved habit of spitting about, and making things dirty; but, besides, that, I have no doubt that the tenacity of the mucus is frequently a cause of it. It causes an unpleasantness; which the patient attempts to remove, by hawking and spitting. Some spit constantly in this disease, when it is not intense. I had a patient who was constantly insane; but who, about every fortnight or ten days, had a paroxysm. When he was in a moderately insane state, he spat nearly

<sup>a</sup> The foregoing extract, and some further details of Lord Erskine’s speech on the occasion, will be found in Professor Amos’s *Lecture on Insanity*; published in the “*Medical Gazette*,” for July 2, 1831. (No. 187; Volume 8; Pages 420 to 423.)

a pint a day; but as soon as an aggravation of the symptoms approached, he spat less; and as soon as the paroxysm was established, he never spat at all. Then, when it was declining, he began to spit again; and when it was over, he spit as profusely as ever. We sometimes observe extreme hunger, and extreme thirst; but sometimes there is an absence of both hunger and thirst. The patient seems to have no desire for either food or drink. Costiveness is very common in the disease; and sometimes we observe great muscular strength; so that an exertion is made, far beyond what is possible in health. Sometimes insane people scarcely sleep at all. They will pass many days, perhaps weeks, with very little sleep; sometimes without any.

*Preceding Signs of Insanity.*—Insanity sometimes begins suddenly; and this is particularly the case where the hallucination relates to a propensity. Persons have sometimes been suddenly seized with an irresistible propensity; and other forms—where there is an absurd notion, or where there is general delirium—may also begin suddenly. For the most part, however, insanity is ushered in by an oddity of manner and behaviour. There is a great degree of loquacity noticed. Persons talk much more than they are accustomed to do; and will burst into foolish fits of laughter. On the other hand, they are sometimes observed to be very taciturn. On other occasions persons, before the disease, are observed to be extremely passionate;—in a different state as to temper to what they are accustomed to be; and some, instead of being passionate, are sulky. Some are extremely civil. I have known such civility, as to be quite extravagant. They will beg us to stop to dine, when we have dined already: they will beg us to stop to supper; and then to take a bed. I have been astonished; and have afterwards learned, that these good people were in a madhouse. Frequently, too, there is a quickness of manner. There is no loquacity,—no civility;—but a hurried way of doing every thing. Frequently there is observed a want of a proper attention to their affairs. They do not take the same interest in their affairs, that they did before. Again: this disturbance of feeling is frequently observed before the full formation of the disease. There is a want of affection to relations and friends; and, more or less, a change of general habits. These are the chief circumstances which precede the full establishment of the disease, when it does not come on suddenly.

*Duration.*—With regard to the continuance of the disease, it will vary from a few weeks, to the rest of the individual's life.

Madmen have lived to the age of eighty-seven. Mr. Tuke, in his account of the patients at the "Retreat,"<sup>a</sup> says that there were eleven patients there, between sixty and seventy years of age; four, between seventy and eighty; and one had arrived at the age of eighty-seven: yet, upon the whole, there can be no doubt that insanity shortens life. If a person in insanity live to a great age, it is lucky (or unlucky) for him; but, in a great number of instances, such persons do *not* live to be very old; just as is the case in connate idiocy. Persons who have congenital idiocy, generally die before they arrive at the middle period of life.

*Rare in Childhood.*—It very rarely, comparatively, occurs in children. The unsoundness of intellect in children is, in general, *idiocy*. Children have very weak passions. They are very little influenced by external circumstances, before mixing with the world, and forming connexions; and, of course, their passions are little liable to be unfavourably excited; and they have much less intellect than adults;—so that, altogether, they are much less subject to insanity. Still, however, children *may* be insane. Although their unsoundness is usually *idiocy*, in various degrees, yet occasionally they are *insane*. Dr. Haslam<sup>b</sup> gives cases of insanity in a child; and so does Mr. Greenwood. I think I have seen several instances of this; where it has been characterized by no delusion, but by very violent rage. Whether, when it begins in childhood, it continues for a long life, I do not know. I cannot say whether such individuals do, or do not, die prematurely.

<sup>a</sup> See Page 551.

<sup>b</sup> See his "Observations on Madness and Melancholy." Chapter 4.

*Remissions and Intermissions.*—But although insanity may continue during the rest of the patient's life, it sometimes has remissions, and even *intermissions*. People are not only much less mad at one time, than at another; but sometimes they are not mad at all. These intervals of sanity, are called "*lucid intervals*;" but, for the most part, a lucid interval is nothing more than the diminution of excitement. The patient is not less mad, but he is less violently excited than before; and therefore it is fancied that he is sound; but, in a great number of these cases, we have only to touch the string, and the madness shows itself again;—the patient being only more tranquil,—less *evidently* mad than before. The greatest caution is required in believing that a person is in a lucid interval; that is, in believing that a person is in an intermission of the disease.

*Sometimes Periodical.*—Occasionally the disease is not only intermittent, but periodical. I was once shown, in a madhouse, an individual who was said to be deranged, for a certain time, every three years. I was applied to by a patient in 1814; and, as the case struck me, I made a particular note of it. He was forty-one years of age; and, five years before, a stone had struck him on the temple. The following and three subsequent years, in the month of March, he had paroxysms of laughing, yawning, stretching, and convulsions; the secretion of urine was sometimes copious; and sometimes scanty; there was great vivacity of spirits; he spoke and believed all sorts of absurdities; and his bowels became costive at that time, though at other times they were freely open. 'This was an instance of insanity. He was only mad in March;—the time at which *hares* are said to suffer derangement. The disease evidently arose from the blow inflicted on the temple, five years before.

*Alternating with other Diseases.*—The disease will sometimes intermit, alternately with other diseases. It has been observed to alternate with disease of the lungs. I was once, when a student, shown a patient in Guy's Hospital, who died of phthisis. I understood that he had been previously deranged; and that as soon as derangement ceased, phthisis began; but he was previously considered phthisical. Whether he *was* in a state of phthisis, I cannot say. The stethoscope<sup>a</sup> was not used then, neither was the ear; but he was *considered* to be in a state of phthisis. He had pectoral symptoms; the insanity ceased; all the pectoral symptoms increased; and he died.

*Usual Mode of Termination.*—Insanity may exist for a long time, and then cease. Dr. Rush *speaks* of spontaneous cures after *eighteen* or *twenty* years; but, in one case, he *witnessed* recovery after *nine* years' duration. Very often, however, insanity terminates in fatuity;<sup>b</sup> and when it so ends, the fatuity is called "*dementia*."<sup>c</sup> Idiocy, fatuity, and dementia (I mentioned) were in reality the same thing; but if idiocy come on in after life, it is called "*fatuity*;" and if fatuity be the consequence of insanity, it is called "*dementia*." But it is to be remembered, that if madmen live to be old,—and some live to be *very* old, their mind, deranged as it is, must decline in the course of nature;—just as the minds of *sane* people decline;—just as *all* our minds will decline; and therefore one can hardly say that insanity has produced dementia; for the *insane* mind must fall into second childhood, exactly like the *sane* one. The disease, however, very frequently terminates, or is joined at last, by palsy; or perhaps by apoplexy; which proves fatal.

### c. Morbid Appearances.

*Lesions frequently Evade Detection.*—When persons die of insanity, we (for the most part) find nothing sufficient to explain the symptoms. There is, perhaps, no appearance of disease in the head;—especially if the person die early, and be inspected very soon after death. But we should remember, that although frequently nothing is found to explain the symptoms, very few brains are dissected in a proper man-

<sup>a</sup> From *σπνθος*, the chest; and *σκοπεω*, to explore.

<sup>c</sup> From "*de*," without; and "*mens—mentis*," mind.

<sup>b</sup> From "*fatuus*," silly.

ner. Most persons run over an examination of the brain more quickly than any other part. It takes so much time to open the head, that the rest of the business, for the most part, is hurried over; and many who do examine the brain, are not qualified for such an examination. Notwithstanding all this, however, there can be no doubt that little or nothing is frequently found in the brain of insane persons;—just as is the case in the stomach, in dyspeptic people. The stomach of a dyspeptic person, when opened, could not, in the greater number of cases, be distinguished from that of other persons, who have died with an excellent digestive apparatus. After pure asthma, we cannot tell that the individual has been subject to the affection.

*Insanity Corporeal, though not necessarily Structural.*—The foregoing, therefore, is no argument against the disease being an affection of the brain. A disease may be *corporeal*, and yet not be *structural*;—no affection of any organ may take place. It does not follow, because we say insanity is *corporeal*, that it is not a disease of the *mind*. We know nothing about that, except as to this world; and it is with this world that medical men have to do. It is a *corporeal* disease; but that does not imply that it must be a change of *structure*. A change of *function* may be quite sufficient. In diabetes, which destroys life, I have frequently opened bodies; and have not seen any evidence of organic disease. It is easy to conceive that this must be the case, if we remember, that individuals who have been mad for years have, just before death, recovered completely. A lady of rank, in whose family there is insanity, told me, that her husband had been deranged for a great number of years; and at length he died; but just before death he recovered his senses. Dr. Marshall, who was formerly a teacher of anatomy in London, mentions a case where recovery from insanity occurred a few hours before death. Now if the disease had arisen from a *structural* affection of the brain,—if the brain had been so disorganized that it could not perform its functions, such an event could not have occurred.

*Evidences of Cerebral Disease.*—Insanity proves itself to be a cerebral affection, as much as dyspepsia proves itself to be a disease of the stomach. But we may have *anatomical* proof in these cases; for, when the disease has continued long, we generally find some mark of disease in the head. We do not find any thing to explain the insanity; but we find something that shows there has been suffering in the head. For example:—there is often fluid in excess in the brain, or *upon* the brain; or the membranes of the brain are thicker than usual; or they are opaque. The bones of the head are very frequently thickened likewise; the external table remains in its proper situation; but the diploe between the two is increased. A deposition takes place there, and the bones become thicker; and, not only so, but sometimes they acquire a degree of hardness equal to that of ivory. Insanity, it is true, is not situated in the bones of the head; but when there is such thickening of the bones, and the *membranes* are thickened, and effusion is found in the membranes, it shows that the head has been suffering.

*Thick Skulls.*—Gall mentions that, in many suicidists,—in fact, he says in *all*,—and frequently in great criminals, where there was no efficient reason for the action of which they had been guilty,—where they had been influenced by violent feelings only,—he found the bones dense and thick. Greeding mentions that, in two hundred and sixteen maniacs, he found the bones of the cranium very thick in one hundred and sixty-seven. In one hundred *furious* maniacs, he found in sixty-eight that the bones of the cranium were very thick. Out of thirty imbecile individuals, he found the bones of the cranium very thick in twenty-two. Gall mentions another interesting fact; which is that, in the extreme old age of maniacs, the bones may grow thin again;—just as they do in sane individuals. It is well known that, in sane individuals, the bones become very thin in certain parts; and though in insanity we may have them thickened, yet they will become thin again.

*Local Lesions of the Brain.*—Besides these appearances, we may find various diseases in the brain itself; but we must not be surprised if, in cases which are not of long standing, we do not find any disease at all. If the case be of long standing,

and the bones are diseased, we may also find disease of other parts. I had a case, which occurred in a woman who had a disposition to injure herself: and there was violent pain in each ear. She was deformed, and laboured under chronic bronchitis. She was placed near a window, caught cold, and died suddenly. After

\* A female, aged thirty-one, was admitted [into St. Thomas's Hospital] on the fifteenth of February [1831]; saying that she had been ill two months. It was represented to me [Dr. Elliotson] as a nervous case. The symptoms were, a propensity to injure some part of herself; and she had "no ease and comfort" (these were her expressions) till she gave way to it. "The part that she desires to injure" (says the case-book) "does not continue to be the same for above an hour at a time; but, as soon as the desire to injure one part ceases, she desires to injure another. The mode in which she is anxious to injure herself, is simply by what she calls her own internal efforts. She does not desire to cut herself, or dash her head against the wall, or to poison herself; but to injure herself simply by muscular efforts, unaided by external objects;—so that she will hold her breath for the purpose of suffocating herself; she will twist her head to one side, in order to strain and break all the muscles and tendons on the other side of the neck; she will sometimes force her breath into her ears, so as to endeavour to burst them; and make all the efforts she can, to strain and force her eyes out of her head." She was quite sensible that this was a morbid state, and lamented it exceedingly. She wondered what was the matter with her; and said that, before this affection, she had always had a strong mind, and could restrain her feelings; but now she had no control over her inclinations. Her spirits were greatly depressed, on account of finding herself in this horrid state. I could discover no other morbid condition of the mind. Her judgment, on all points, was good; she was under no delusion of any kind; and yet she possessed this desire. There could be no condition of the case being feigned; for, while you were talking to her, and she to you, you saw her head twist on one side violently; and could discern that she was silently making an effort to rupture some part of the neck, or to overstrain it; and you would see her eyes close, from the efforts that she appeared to be making. Her head was thus constantly in motion; and I thought, at first, she had shaking palsy of the head, or partial chorea; but that was not the case, for she told me, that it arose from her own incessant efforts to strain her head and neck. This appearance of the head was continually going on.

But the proof that there was no deception in all this, was not merely that you saw these efforts going on too naturally and too intensely to be counterfeited, but there were a number of other symptoms. She was drowsy, had pain in her head, a sensation of pressure there, and (she said) a sensation of "opening and shutting" in her head from time to time; but this was chiefly felt at the sides of her head, immediately above the ears; and shot across the back of the head, in a straight line. This sensation was felt immediately above the ears, and extended backwards till the two sensations—the sensations of each side—met. Now she might have said that she had this pain when she had not; but it is a remarkable fact, that this was an alleged seat of the pain. Moreover, there were sensibly evident symptoms of disease; for her breath was excessively offensive; so that those who were much about her complained of it, and could not long hold their heads near her. Frequently it turned my stomach (which is a pretty strong one); and her tongue was excessively foul;—being coated with dirty, thick mucus. She was in a situation of life, too, which rendered it exceedingly improbable that there could be any deception; for she kept a school, and had (in addition) a little trade in the way of a peculiar kind of needle-work; and, by means of them both, she gained a very excellent livelihood. She was exceedingly respected, in her own neighbourhood, by medical men who knew her, and by every one else. This I learned from the medical gentleman who sent her here [St. Thomas's Hospital], to be under my care. She had hardly any sleep, when she first came to the hospital. Besides the pain running backwards from each ear, she complained of a strong pulsation in that part.

You will sometimes meet with a case, where the person has a sound judgment on every point,—is not at all insane in his intellectual faculties; but is wrong with respect to some one feeling. He finds it irresistibly violent; and, perhaps, it is vitiated at the same time. Now this was the case here. This woman was labouring under a propensity which is called, by Dr. Gall, "the propensity to murder," or (in the nomenclature of Dr. Spurzheim, disapproved of by Dr. Gall) "destructiveness;" a propensity, whatever name we give it, bestowed upon animals in general, for the purpose of destroying other animals for the sake of food, and for the purpose of rage; and which exists in us, it has been supposed, in such a form as to give the feelings of rage, anger, or indignation. In this woman there was a diseased manifestation of this propensity; only it was limited to hurting herself. She wished continually to injure herself. But there was still a greater limitation of it, and a very striking peculiarity in the case; inasmuch as she had constantly a desire to effect the object (according to her own account, and as it appeared) only by internal exertion;—not by taking poison, not by cutting herself with an instrument, not even by using her nails for the purpose of lacerating her flesh; but simply by straining, forcing, twisting, stopping her breath, and endeavouring to force out her eyes and her ears. A peculiar circumstance was the pain which she felt, and the throbbing just over each ear, and extending partially around the head. Every gentleman in the habit of going round the hospital, must have heard her say, that the pain

death, over each ear, there were found strong adhesions to the "dura mater;" and the brain itself, just over the part, was in a state of vascularity. In insanity we may find different parts of the brain more or less inflamed; and we may find the appearances which inflammation more or less induces; such as thickening and softening, and various organic affections;—just such as would, *à priori*, be expected.

*Increased Heat of certain Parts of the Head.*—I may mention, in connection with this remark, that over the parts which are particularly excited, we frequently find the temperature higher, than at other parts of the head. Nothing is more common than to find one part of the head hotter than another. If we have been studying for some hours, we feel the temperature of the forehead to be much hotter than it is either at the top, the back, or the sides of the head. So when persons' feelings are excited in insanity, a local increase of temperature is frequently induced. This remark has been made by those, who have more opportunity of observing the fact than myself.

*Georget's Researches.*—[M. Georget has summed up the morbid changes which he considers as authentically connected with madness; and his recapitulation may be looked upon as a tolerably complete statement of the result of anatomical researches into this subject, up to the time when his work on insanity, and the article contributed by him to the "Dictionnaire de Médecine," were published. The following are the principal points:—"Irregular conformation of the *cranium*, the prominences of which are developed irregularly;—those of the right side being generally larger than those of the left;—some skulls having the lateral

was exactly over each ear; and, though it extended, shot from that situation. This was no imagination of mine. I did not lead her to any such declaration. I merely asked if she had a pain in her head; and she said "yes." I then asked her where it was situated; and she pointed out the exact spot. She was repeatedly questioned, by myself and others, afterwards; and she always gave the same answer. This was a very striking phrenological fact.

This woman died;—not of this complaint; for of that she was cured, or nearly so. She was opened; but I was not present. The brain, however, was preserved; and, on examining it, I found nothing; and this was only what might have been expected. In diseases of various parts of the body, you continually open patients, and find nothing;—so many diseases are merely functional. In this case nothing was to be expected, because the woman was cured; but I understand that the "dura mater" adhered to the brain where the pain was felt; that is to say, at the sides, low down;—showing that an inflammatory state had previously existed, and had left its common consequence,—adhesion. I should not omit mentioning, however, that the character of the insane person, even where disproportionate development has not been the predisposing cause, corresponds (in most instances) with the character of the head.

With respect to the treatment of this woman, I considered that an inflammatory affection of that part of the head, was the cause of the pain she experienced. I cupped her behind the ears, to twelve ounces; and gave her calomel (five grains twice a day), and put her on low diet. Leeches were again and again applied to that part. She was admitted on the eighteenth of January; and twenty leeches were applied to the seat of the pain every day, till the eighth of February. From the eighth of February, they were applied every other day, for a fortnight. Her mouth soon became tender; and, as that took place, her tongue became clean, and her breath ceased to be fetid. At last it began to smell of mercury; but the odour was quite changed in character, and was supportable. She twisted her head less and less, and she slept more,—several hours in the night. The pain in the head left her; and she now felt relieved from the disposition to strain and injure herself. She was a deformed woman; and the lungs and heart had hardly any room to play. She was subject more or less to bronchitis; and was seized with an attack, from being placed near a window; and it was necessary, on account of this affection of the chest, to bleed her. She was bled to six ounces, recovered from the bronchitis, was now really well, and was to be dismissed on the following Thursday. On the Saturday, however, being in the ward just as usual,—she was seized (I understand)—for I had left the hospital—with pain in the abdomen; and, in a few minutes, died. The friends came for the body before the inspection could be completed. The head was examined, and also the chest; but nothing morbid was found in either, except the adhesion of the "dura mater" to the brain, above the "meatus auditorius externus." On account of the friends waiting for the body, the examination of the abdomen was not proceeded with; and therefore, the cause of death is unknown. Whether she died from a rupture of any part within the abdomen, I do not know; nor have I any idea of the cause of her death; although I am quite satisfied it was in the abdomen.—"*London Medical Gazette*;" Volume 8; Pages 168 to 176. (No. 179; May 7, 1839.)

diameter of equal extent with the antero-posterior, and the cavities of the base irregular in extent; some skulls (one in twenty) thickened partially or generally, more frequently the bones hard, white without *dipl e*, resembling ivory; some very light. *Dura mater* rarely changed; sometimes adherent to the skull, thickened, containing deposits of bone. *Arachnoid* displaying in places additional laminae of a red or gray colour; sometimes thickened, but smooth. *Pia mater* injected or thickened, and infiltrated with serum;—giving, at first, the appearance of gelatinous deposit. *Volume of the brain* sometimes less than the cavity of the cranium seems to require. Some brains very hard; cut with difficulty; the white substance glutinous, elastic, and suffering distension: more frequently the brain is soft;—the gray matter being pale and yellowish, and the white substance discoloured, of a dirty white, the colour and consistence of these portions almost confounded. The convolutions separated by serosity, and the *pia mater* thickened. Interior cavities of the brain appearing in some instances very large, in others small, often filled with a serous fluid, remarkably clear and limpid; *plexus choroides* exanguious, containing hydatiform vesicles. Partial softening of the brain, erosions, ulcerations of the surface of the ventricles. *Cerebellum* generally softer than the cerebrum, sometimes partially softened. *Mesocephalon*, *medulla oblongata*, and *medulla spinalis*, rarely displaying morbid changes of structure."

*More Recent Researches.*—Considerable additions have been made to the morbid anatomy of the brain, in cases of insanity, since the time of M. Georget. These researches have been conducted chiefly by MM. Bayle, Calmiel, Lallemand, Foville, and Bouillaud. The two former have principally directed their attention to the history of general paralysis; and the pathological details given by them have reference to this disease, which may be termed an adventitious one; but which is so frequently connected with insanity, that its supervention cannot be looked upon as a matter of mere contingency. M. Calmiel's observations resolve themselves into the general conclusion, that unequivocal signs of chronic inflammation of the brain exist in almost every case of this disease complicated with insanity.

Some of the morbid appearances which M. Calmiel considered as proper to the disease, which he terms "*paralyse des ali n s*,"<sup>a</sup> are connected by M. Foville with insanity; and are regarded by that writer as ultimate results of that disease in its protracted stage; when the brain—having long been disordered in function, and especially in the state of the vascular apparatus—passes into a degree of disorganization, no longer compatible with the continued preservation of even physical life.

The changes which the different parts of the encephalon undergo, according to M. Foville, resolve themselves into the signs of recent inflammatory action in acute cases, and the well-known results of long-continued inflammation in chronic and inveterate examples of the same disease. He has noted in the former the chief morbid signs in the gray substance of the brain; such are a red colour, uniform, and very intense; numerous mottled spots, varying from a bright to a violet red, bloody points; minute extravasations of blood; diminished consistence in the thickness of the cortical substance, coincident with a slight increase of consistence in its surface; dilatation of the vessels, and resistance of their parietes. In *acute* cases M. Foville has never observed adhesions of the membranes to the cortical substance. Such adhesions are very frequent in *chronic* cases; and hence, as he conjectures, may be explained the curable nature of *recent* maniacal affections, and the hopeless and incurable state of those patients who have *long* laboured under insanity.

*Morbid Appearances in the Gray Matter.*—The chronic changes of the cortical substance, are increased firmness and density of the superficial part; extending to no great depth, but uniform, and constituting a distinct lamina or layer of hardened consistence; which, torn off, leaves a red, soft, mammillated bed of softened cortical substance beneath. The volume of the convolutions remains natural, or is less

<sup>a</sup> "*Paralysis of the insane.*"

than natural;—owing to a real atrophy, or to the existence of lacunæ; which are the results of a minute extravasation. This morbid change often extends to three or four convolutions on each side of the sagittal<sup>a</sup> suture;—a chasm, filled with serosity, often occupying the place of the absorbed cerebral substance. Coexistent with this state of the encephalon, is that species of atrophy of the cranium, in which the diploë disappears;—leaving a superficial depression on the head. Another morbid state of the cortical substance, is that of uniform and red ramollissement; which is a change very distinguishable from that above described.

*Morbid Appearances in the White Matter.*—The change of the white substance, principally its preternatural hardness and unusual whiteness, resolve themselves, in M. Foville's opinion, into adhesions between the cerebral fibres and the deposition of additional matter;—the results of chronic inflammation. It is well known to those who have studied the works of late anatomists on the structure of the brain, that M. Foville has attempted to demonstrate in the organization of the cerebral mass the existence of distinct planes of medullary substance, superimposed one upon another, and connected in the healthy state by means of a very fine cellular tissue. These planes, thus easily separable in the healthy state, become closely adherent in long-continued cases of madness. M. Foville repeats the observation made by many writers;—that the brains of lunatics are so full of serous fluids, that an abundant serosity flows from the surface of incisions. He likewise observes the presence of small serous cavities, from the size of a millet-seed to that of a nut. This was first noted by M. Esquirol. It is the appearance which the late Dr. Sims has more recently described, as the spontaneous cure of ramollissement. The section of a brain thus perforated, is compared to that of a porous cheese. By M. Foville these cavities are supposed to be the relics of extravasation. Perhaps the opinion of Dr. Sims will be allowed to be the most probable;—that they are the results of softening of the brain. It must be carefully noted, that these changes in the white substance do not belong to insanity, separately existing and uncomplicated with paralysis. In persons affected with the "paralysie des aliénés," they are almost universal. They are likewise found in the brains of old men, whose voluntary movements have become uncertain and vacillating; but more in lunatics whose muscular powers had remained unimpaired.

*The Membranes.*—The changes in the membranes observed by M. Foville may be referred, in like manner, to the various results of meningitis: they are thickenings and adhesions of the *dura mater*, injections of the *pia mater*, and opacity and increased density of the *arachnoid*.

The pathological results deduced from these observations are, that morbid changes in the cortical substance are directly connected with intellectual derangement, and those of the white substance, with disorders of the motive powers. These opinions coincide generally with those of the most accurate morbid anatomists of recent times. It must be observed, that all such changes in the brain and the membranes resolve themselves into the well-known results of inflammation and increased vascular action.

*Thoracic Lesions.*—Diseases in the thorax are often traced in cases of mental derangement. Hypertrophy of the heart is a phenomenon of frequent occurrence. M. Georget declares, that in more than three-fourths of the bodies of insane persons examined by him, there had existed organic disease of the lungs; such as chronic pneumonia, or phthisical degenerations. He says, that phthisis is the cause of death in more than half the maniacs who die in the Salpêtrière. Cavernous excavations are found in the lungs of numerous patients; who, during life (unless the fact has been ascertained by auscultation), are never known to labour under pulmonary disease.

*Abdominal Lesions.*—Of abdominal diseases in insane persons, the most frequent is gastro-enteric inflammation. This has been discovered in a considerable proportion of bodies of persons affected with mental derangement. One of the

<sup>a</sup> From "sagitta," an arrow.

<sup>b</sup> See Page 566.

most remarkable changes in the necroscopy<sup>a</sup> of insane persons, is displacement of the transverse colon. This was observed, by M. Esquirol, in thirty-three out of one hundred and sixty-eight cases of melancholia. The change consisted in an altered position of the intestine; which, instead of traversing the abdomen, was turned into a perpendicular direction, and precipitated behind the pubes. A similar phenomenon has been noticed by Bergmann, Nasse, and Guislain. Organic diseases of the liver are of very rare occurrence in connection with insanity.<sup>b</sup>]

#### d. Causes of Insanity.

*Hereditary Predisposition.*—With regard to the causes of insanity, of course they are *predisposing* and *exciting*;—just as is the case with other diseases. Among the *predisposing* causes, the most remarkable is hereditary predisposition. I should think there is no disease to which the human frame is subject, which can be so hereditary as insanity. When I say “disease,” I mean *disposition* to the disease; because if a person do not have a disease break out till he is thirty, forty, fifty, sixty, or even seventy years of age, yet if the disposition to it be given to him by his parents and ancestors, we say it is hereditary. That is the ordinary mode of speaking; but some people object to this word “*hereditary*.” I should suppose, however, that if a man inherit an estate from his father, even if he do not come into its possession till he is ninety years of age, it is just as hereditary as if he receive it the day he is born. It is a mere quibble to limit the word “*hereditary*.” But insanity, in a large number of cases, is hereditary; and I do not think it is so difficult to wear out the hereditary disposition to any other disease, as it is that to insanity. It seems to require more of dilution,—more crossing of the breed, than any other affection; for it comes on even in the third and fourth cousins, and although it may have disappeared in one generation, it so frequently returns, that there is the greatest danger of its arising in almost every other descendant. Scrofula, gout, and various other complaints, will cease from good management; and in favourable circumstances; but as to the disposition to insanity, it is certainly one of the most undilutable (if I may use the expression) that can be imagined.

*Importance of attending to this Cause.*—The importance of attending to the existence of insanity in families, has been very much dwelt upon by some writers; and I must confess that, if I were going to be married, there is no disease that I should be more anxious to inquire whether the family was free from, than this. Dr. Spurzheim, among others, has written on the subject; but it is just as well dwelt upon by Burton, in his “*Anatomy of Melancholy*,” in his usual facetious and singular manner. He enumerates hereditary disposition among the causes of melancholia, and says:

“*Parents a Cause by Propagation.*—That other inward inbred cause of melancholia, is our temperature, in whole or part, which we receive from our parents. Such as the temperature of the father is, such is the son’s; and look what disease the father had when he begot him, such his son will have after him, and is as well inheritor of his infirmities as of his lands.” He then enumerates a number of hereditary diseases, and proceeds to remark—“Some other causes are given, which properly pertain to, and proceed from the mother. If she be over dull, heavy, angry, peevish, discontented, and melancholy,—not only at the time of conception, but even all the while she carries the child in her womb,—her son will be so likewise affected, and worse. If she grieve over much, be disquieted, or by any casualty be affrighted and terrified by some fearful object heard or seen, she endangers her child, and spoils the temperature of it, for the strange imagination of a woman works effectually upon her infant.” He concludes thus: “So many several ways are we plagued and punished for our fathers’ defaults; insomuch that,

<sup>a</sup> From νεκρος, dead, and σκοπεω, to examine.

<sup>b</sup> “*Library of Medicine*,” Volume 2; Pages 126 to 128.

as Fernelius truly saith,—‘It is the greatest part of our felicity to be well-born; and it were happy for human kind, if only such parents [persons] as are sound of body and mind, should be suffered to marry.’ An husbandman will sow none but the best and choicest seed upon his land; he will not rear a bull or a horse, except he be right-shapen in all parts; or permit him to cover a mare, except he be well assured of his breed. We make choice of the best rams for our sheep; rear the neatest kine; and keep the best dogs. ‘Quanto id diligentius in procreandis liberas observandum!’ (‘And how careful, then, should we be in begetting of our children!’) In former times, some countries have been so chary in this behalf,—so stern, that if a child were crooked or deformed in body or mind, they made him away. So did the Indians of old (by the relation of Curtius;) and many other well-governed commonwealths, according to the discipline of those times. ‘Heretofore, in Scotland,’ saith Boethius,<sup>a</sup> ‘if any were visited with the falling sickness, madness, gout, leprosie, or any other such dangerous disease, which was likely to be propagated from the father to the son, he was instantly gelded; a woman kept from all company of men; and if by chance, having some such disease, she were found to be with child, she with her brood were buried alive.’ And this was done for the common good; lest the whole nation should be injured or corrupted. ‘A severe doom,’ you will say, ‘and not to be used among Christians;’ yet more to be looked into than it is. For now, by our too much facility in this kind, in giving way for all to marry that will,—too much liberty and indulgence in tolerating all sorts, there is a vast confusion of hereditary diseases;—no family secure;—no man, almost, free from some grievous infirmity or other; when no choice is had, but still the eldest must marry, as so many stallions of the race. Or, if rich,—be they fools or dizzards,<sup>b</sup> lame or maimed, unable, intemperate, dissolute, exhaust through riot,—as was said, ‘jure hereditario sapere jubentur;—’ they must be wise and able by inheritance.’ It comes to pass that our generation is corrupt; we have many weak persons, both in body and mind; many feral<sup>c</sup> diseases raging amongst us; crazed families;—*parentes, preemptores*;<sup>d</sup> our fathers bad, and we are like to be worse.”<sup>e</sup>

Now this is good advice; for though it is not to be carried to the unwarrantable pitch of gelding unfortunate people, yet undoubtedly this matter ought to be attended to much more than it is. I think it sinful to marry a person in whose family there are many instances of insanity; and it is appalling to read the accounts of “deaf and dumb” charities, and “blind” charities; where it is stated that individuals have produced child after child deaf and dumb, or blind. I think, when one or two children have been produced blind or deaf, that it is wickedness for procreation to be continued. Sometimes as many as six children are born deaf or blind in the same family. I should think it would be desirable, in such circumstances, to ascertain (if possible) from which of the family the disease arose; and that divorce would then be very allowable;—so that only one should be deprived of marriage rites.

As an illustration of the hereditary nature of insanity, Dr. Burrows says, that six cases out of seven, in his private practice, were of that class.<sup>f</sup> In the Salpêtrière, there were three hundred and twenty female lunatics; one hundred and five of whom had the disease hereditarily. Out of two hundred and sixty-four cases treated by Esquirol in his private practice, one hundred and fifty were hereditary. Where insanity is hereditary, it is very common to see other members of the family, not deranged, but afflicted with some nervous disease or other. I know one family, where two or three are deranged. The father is not deranged; but he speaks badly, and has twitches of the face. Two other children of the family are sane; but have twitches of the face. Where one is insane, another is frequently a little odd in his manner, or odd in his thoughts; but not

sufficiently so to be called "deranged." Where there is insanity in a family, some individuals have very strong feelings; but not so strong as to overbalance the mind, and produce insanity.

*Moral Causes.*—Among the frequent causes of insanity, are what are termed "moral causes;"—consisting in violent excitement of the feelings; but these, for the most part, are innocuous, unless there be hereditary predisposition. A person will, in general, bear the most violent excitement from external circumstances, unless there be a predisposition to the disease. We every day see persons suffer the greatest reverses,—the most dreadful privations,—the severest bereavements of those who are dearest to them; so that they are overwhelmed for a time; but they are not ruined in mind for ever. There must be a certain weakness of mind, or a bad constitution of mind, or an ill-regulated state of mind, or a disposition to insanity in general, for these causes to take effect. At any rate, the mind may be so strong, and the faculties so well formed, and so well balanced, that the strongest moral causes will not upset the man. With regard to these causes, it is said that joy has excited insanity, even more frequently than grief. Human nature seems doomed to suffer. Most of us, every day of our lives, suffer something or other,—little or much; and human nature seems more capable of enduring grief than of bearing joy.

*Partial Development of the Brain.*—There can be no doubt, I think, that one predisposing cause to insanity, is a partial development of the brain. In many people who are deranged through the feelings, (which is the case with the greater part of deranged persons,) certain parts of the brain are more developed than others;—so as to be more than a match for the rest of the head; and they have suffered so strong an excitement, as to have over-balanced the powers of mind. This occurs in a great number of cases. Where there is mental delusion, I believe, in most cases, it arises from some strong passion. When a man fancies himself an emperor, it is on account of the excessive development of the organ of "self-esteem." When a person fancies himself to be the Deity,<sup>a</sup> it is generally from the same circumstance. The delusion generally springs from excess of pride. When a person is convinced that a conspiracy is formed against him,—that attempts are made against his life every day, or attempts are *meditated*;—when he believes things which have no reality, and sees demons<sup>b</sup> coming to injure or to destroy him,—it is generally from an over-excitement of the depressing passions. That is to say, his fear has got the better of his pride; and, being under the influence of fear, he afterwards becomes the subject of delusion.

*Exciting Causes: Intense Application to One Point.*—With respect to *exciting* causes, there can be no doubt that long application to one particular point, is occasionally the cause of insanity. It was evidently intended by Providence, that we should employ all the faculties with which we are blessed;—not merely that we should use *one* arm, but *both*; not merely one *leg*, but *both*; not one *faculty of the mind*, but *all* in their turn; so as to strengthen the whole, and enjoy every feeling of the mind, as well as every intellectual faculty. If, then, a person dwell intensely upon one idea,—so as not to employ the faculties of his mind at large, and employ all the feelings; if one only be engaged to the exclusion of the rest; so that ideas of *one* kind are not counterbalanced by ideas of *another*;—the person may at last persuade himself of any thing, and become mad. We cannot have a better illustration of this, than in Johnson's "Rasselas;" where, from a philosopher studying astronomy;—not hearing discourses on other subjects; not having his mind drawn to other topics; not enjoying one of the greatest delights in life,—conversation with his fellow-men; but shutting himself up, being abstracted on one point (namely, the motion of the heavenly bodies);—he at last became deranged, and fancied that he had the command of them. He was cured by being taken into society again.<sup>c</sup>

<sup>a</sup> See Pages 560 and 581.

<sup>b</sup> See Page 581.

<sup>c</sup> I [Imlae] have just left the observatory of one of the most learned astronomers in the world; who has spent forty years in unwearied attention to the motions and appearances of

*Fever, and Injuries of the Head.*—Insanity has frequently been excited by fever, and common inflammation of the brain. It has been excited by heat applied to the body at large; but particularly to the head; what is called "*insolation*" has frequently made men mad. Mechanical injury (as may readily be imagined) has

the celestial bodies, and has drawn out his soul in endless calculations. I was introduced as a man of knowledge, worthy of his notice. I visited him with more and more frequency; and was, every time, more enamoured of his conversation.

I had quickly reason to imagine, that some painful sentiment pressed on his mind. He often looked up earnestly towards the sun, and let his voice fall in the midst of his discourse. He would sometimes, when we were alone, gaze upon me in silence, with the air of a man who longed to speak what he was yet resolved to suppress. He would often send for me with vehement injunctions of haste; though, when I came to him, he had nothing extraordinary to say: and sometimes, when I was leaving him, would call me back, pause a few moments, and then dismiss me.

At last, the time came when the secret burst his reserve. We were sitting together, last night, in the turret of his house;—watching the emersion of a satellite of Jupiter. A sudden tempest clouded the sky, and disappointed our observation. We sat awhile silent in the dark; and then he addressed himself to me in these words:—"Imlac, I have long considered thy friendship as the greatest blessing of my life. Integrity without knowledge is weak and useless; and knowledge without integrity is dangerous and dreadful. I have found in thee all the qualities requisite for trust, benevolence, experience, and fortitude. I have long discharged an office which I must soon quit at the call of nature; and shall rejoice, in the hour of imbecility and pain, to devolve it upon thee."

I thought myself honoured by this testimony; and protested, that whatever could conduce to his happiness, would add likewise to mine.

"Hear, Imlac, what thou wilt not without difficulty credit. I have possessed for five years the regulation of the weather, and the distribution of the seasons. The sun has listened to my dictates; and passed from tropic to tropic by my direction; the clouds at my call have poured their waters, and the Nile has overflowed at my command; I have restrained the rage of the dog-star, and mitigated the fervours of the crab. The winds alone, of all the elemental powers, have refused my authority; and multitudes have perished by equinoctial tempests, which I have found myself unable to prohibit or restrain. I have administered this great office with exact justice, and made to the different nations of the earth an impartial dividend of rain and sunshine. What must have been the misery of half the globe, if I had limited the clouds to particular regions, or confined the sun to either side of the equator?"

I suppose he discovered in me, through the obscurity of the room, some tokens of amazement and doubt; for, after a short pause, he proceeded thus:—

"Not to be easily credited will neither surprise nor offend me; for I am, probably, the first of human beings to whom this trust has been imparted. Nor do I know whether to deem this distinction a reward or punishment. Since I have possessed it, I have been far less happy than before; and nothing but the consciousness of good intention, could have enabled me to support the weariness of unremitted vigilance."

"How long, sir," said I, "has this great office been in your hands?"

"About ten years ago," said he, "my daily observations of the changes of the sky, led me to consider whether, if I had the power of the seasons, I could confer greater plenty upon the inhabitants of the earth. This contemplation fastened upon my mind; and I sat days and nights in imaginary dominion, pouring upon this country and that the showers of fertility, and seconding every fall of rain with a due proportion of sunshine. I had yet only the *will* to do good; and did not imagine that I should ever have the *power*. One day, as I was looking on the fields withering with heat, I felt in my mind a sudden wish, that I could send rain on the southern mountains, and raise the Nile to an inundation. In the hurry of my imagination, I commanded rain to fall; and, by comparing the time of my command with that of the inundation, I found that the clouds had listened to my lips."

"Might not some other cause," said I, "have produced this concurrence? The Nile does not often rise on the same day."

"Do not believe," said he, with impatience, "that such objections could escape me. I reasoned long against my own conviction, and laboured against truth with the utmost obstinacy. I sometimes suspected myself of madness; and should not have dared to impart this secret but to a man like you;—capable of distinguishing the wonderful from the impossible, and the incredible from the false."

"Why, sir," said I, "do you call that incredible, which you know, or think you know, to be true?"

"Because," said he, "I cannot prove it by any external evidence; and I know too well the laws of demonstration, to think that my conviction ought to influence another, who cannot (like me) be conscious of its force. I therefore shall not attempt credit by disputation. It is sufficient that I feel this power;—that I have long possessed, and every day exerted it. But the life of man is short. The infirmities of age increase upon me; and the time will soon come, when the regulator of the year must mingle with the dust. The care of ap-

produced the same thing. An instance is mentioned of a foreign surgeon having trephined a man, for a large wound of the temporal bone; and, when the wound was healed, the man could not refrain from stealing. He was an honest man before; but after the wound he had an irresistible desire to steal. The surgeon was something of a philosopher. The people could not imagine how stealing was a disease; but the gentleman who had performed the operation, was convinced that it was; and, by representing the case scientifically to others, he procured the liberation of the individual.

*The Puerperal State.*—The puerperal state is, no doubt, one cause of insanity. During labour, women are subject to such an irritation of the head, and probably of the spinal marrow, as to fall into insensibility and convulsions; and, in like manner, puerperal women frequently become insane. They become so, in general, from the third or fourth day after delivery, up to the fourteenth or fifteenth; and, now and then, they will become insane during suckling. Dr. Gall says, that he knew four women who, in pregnancy only, had a desire to steal. They had a *local* or *partial* insanity; and not, as we usually see in the puerperal state,—a *general* insanity.

*Old Age.*—I think old age has a tendency to produce insanity; and there it is, in general, insanity of *feeling*. The intellectual faculties decline when we grow old; and the feelings frequently fall into a state of excitement. I have frequently seen old men, whose intellectual faculties have become much decayed, become

pointing a successor, has long disturbed me. The night and the day have been spent in comparisons of all the characters which have come to my knowledge; and I have yet found none so worthy as thyself. Hear, therefore, what I shall impart, with attention such as the welfare of a world requires. If the task of a king be considered as difficult,—who has the care only of a few millions, to whom he cannot do much good or harm,—what must be the anxiety of him, on whom depends the action of the elements, and the great gifts of light and heat! Hear me, therefore, with attention.

“I have diligently considered the position of the earth and sun; and formed innumerable schemes, in which I changed their situation. I have sometimes turned aside the axis of the earth, and sometimes varied the ecliptic of the sun; but I have found it impossible to make a disposition by which the world may be advantaged. What one region gains another loses, by any imaginable alteration;—even without considering the distant parts of the solar system, with which we are unacquainted. Do not, therefore, in thy administration of the year, indulge thy pride by innovation. Do not please thyself with thinking, that thou canst make thyself renowned to all future ages by disordering the seasons. The memory of mischief is no desirable fame. Much less will it become thee to let kindness or interest prevail. Never rob other countries of rain, to pour it upon thine own. For us [Egyptians] the Nile is sufficient.”

I promised that, when I possessed the power, I would use it with inflexible integrity; and he dismissed me,—pressing my hand. “My heart,” said he, “will be now at rest; and my benevolence will no more destroy my quiet. I have found a man of wisdom and virtue, to whom I can cheerfully bequeath the inheritance of the sun.” . . . .

The sage confessed to Imlac, that since he had mingled in the gay tumults of life, and divided his hours by a succession of amusements, he found the conviction of his authority over the skies fade gradually from his mind; and began to trust less to an opinion that he never could prove to others, and which he now found subject to variation, from causes in which reason had no part. “If I am accidentally left alone, for a few hours,” said he, “my inveterate persuasion rushes upon my soul, and my thoughts are chained down by some irresistible violence; but they are soon disentangled by the prince’s conversation, and instantaneously released at the entrance of Pekuah. I am like a man habitually afraid of spectres; who is set at ease by a lamp, and wonders at the dread which harassed him in the dark; yet, if his lamp be extinguished, feels again the terrors which he knows that when it is light he shall feel no more. But I am sometimes afraid, lest I indulge my quiet by criminal negligence; and voluntarily forget the great charge with which I am entrusted.” . . . .

“My reason,” said the astronomer, “has been so long subjugated by an uncontrollable and overwhelming idea, that it durst not confide in its own decisions. I now see how fatally I betrayed my quiet, by suffering chimeras to prey upon me in secret; but melancholy shrinks from communication; and I never before found a man to whom I could have imparted my troubles, though I had been certain of relief. I rejoice to find my own sentiments confirmed by yours;—who are not easily deceived, and can have no motive or purpose to deceive. I hope that time and variety will dissipate the gloom that has so long surrounded me; and that the latter part of my days will be spent in peace.”—*History of Rasselas, Prince of Abyssinia. By Samuel Johnson, LL. D.* Chapters 40, 41, 42, 43, 46, and 47.

exceedingly passionate, suspicious, and at last delirious;—totally unlike any thing they were before, and in such a state as I considered to be madness.

*Excesses of all Kinds.*—Excess of all kinds will induce this disease. Sexual indulgence is always enumerated among the causes of insanity; but very frequently, I have no doubt, excessive sexual indulgence, as well as *improper* indulgence, is the result of a morbid state of the brain itself. I have no doubt that a great many who indulge in sexual pleasures, beyond what is intended, (thinking of nothing else,—running riot every day,) do so through a morbid excitement of the head;—a diseased state. They live in indolence; and, not having any thing else to do, they select this as a good occupation. I have no doubt that many persons indulge in this way, till they go mad; but I am quite satisfied that this is not always the case; but that the state which ends in insanity, has originally produced a violent excitement in that particular direction.

*Cessation of Discharges.*—The cessation of discharges will have the same effect. Persons have gone mad from the drying up of an ulcer or an issue; and the disease has sometimes arisen in the way of metastasis. When a disease to which a person has been long accustomed disappears, sometimes insanity will occur. I have seen it come on after gastrodynia; and it is said to have occurred, sometimes, after itch, and other diseases. It is merely a disease of the brain; and therefore persons afflicted with it are subject to all other affections. Diseases of the liver and intestines will sometimes produce a sympathetic excitement of the head; so as to occasion insanity. Disease of other parts, on the other hand, will sometimes *impede* this disease.

*Agency of the Devil.*—I need not say that the devil has nothing to do with this disease, any more than any other; but some physicians say, that the disease is caused by the devil, or demons. The devil is a particular individual, but demons are supposed to be the spirits of departed persons. Even sound writers give an account of insanity being produced by the devil. Sauvages, the first writer on nosology, says that he really cannot agree with those German physicians who, one and all, say that persons possessed by the devil do wonders. Hoffman and Sauvages state, that signs are produced by demoniacal agency. One of these authors says, in the first place, that when a person is mad through demons, he has a demoniacal manner. He has not only heard them vociferate unusually loud, and make most unusual gestures, but perform wonderful and unusual motions of the body. In the second place, he says that these motions of the body (convulsions) came on suddenly, without any preceding disease. Thirdly, that such patients are very blasphemous; and look very much like the devil. Fourthly, that they have a knowledge of men; and reveal secret and particular objects faithfully. Fifthly, that they have a knowledge of unknown tongues;—not *foreign* tongues. To be conversant with *unknown* tongues, is much more clever than knowing *foreign* tongues. We should all be desirous to know the latter in this way; because it would save us the trouble of learning them. Sixthly, he says, that they have unusual strength; and, seventhly, that they vomit singular things;—such as hairs, pieces of flint, pins and needles, and things of that description; and that they not only discharge them from the stomach, but even sometimes from the eyes. When this occurs, we may be quite sure a person is possessed of the devil. Physicians have now driven demons from the nosology; and Voltaire says, that the devil is always much mistaken when he addresses himself to doctors;—that we are the men who drive him out.

#### *e. Diagnosis and Prognosis.*

*Phrenitis.*—As to the general *diagnosis* of insanity, we have to distinguish it from phrenitis, from fever, and from delirium tremens. There can be no doubt that, in insanity, there frequently are signs of inflammation;—that there is pain and heat of the head; quickness of pulse; thirst; a dry and foul tongue; high coloured urine; and a throbbing of the temples;—just as in delirium from inflam-

mation. But, in the first place, insanity is a *chronic* disease; whereas phrenitis and fever are not; and, in the next place, although there are these symptoms of inflammation of the brain in insanity, when it *first begins*, (so that we may be in doubt as to whether it is phrenitis—common inflammation—or not,) yet we have this criterion;—the insanity is out of all proportion to the signs of inflammation. I know of no other mode of discerning the true nature of the case, when signs of inflammation are present, than this. But in insanity, we may have no signs of inflammation at all; so that there can be no doubt as to its not being a case of inflammation of the brain. The state of the brain may be much the same, and there may be something of quibbling in it; but the distinction is important: because, if there be decided inflammation of the brain, we may set to work according to the strength of the patient; and, by antiphlogistic measures, do great good; whereas, if the signs of insanity be out of all proportion to the signs of inflammation, and it be taken for a mere case of phrenitis, we shall in general do great harm. Antiphlogistic measures are, generally, very useful in the *beginning* of insanity, when there are more or less signs of inflammation; but if the signs of aberration of mind, be out of proportion to the signs of inflammation, they will do serious mischief. Indeed, if we go boldly to work, and think that it is a case of inflammation, antiphlogistic measures will frequently cause the patient to sink; or they will perpetuate the disease. It is of importance to consider, whether the signs of inflammation, and the signs of insanity, are in proportion to each other. If the latter be only in proportion to the former, the case may be treated as inflammation. Our diagnosis will be also assisted, by knowing whether the individual has ever been insane before, and whether there is insanity in his family; because, if these circumstances do exist, and if we think that disturbance and inflammation are coexistent, and not one dependent upon the other, then we must not have recourse to antiphlogistic measures.

*Fever.*—As to the delirium of fever, it is easily known (in general) by the peculiar hollowness of the eyes, the vomiting, the extreme loss of appetite, the pain of the loins, and so on. One cannot easily mistake a case of this description; and when delirium afterwards comes on, if it be violent, it is in proportion to the signs of inflammation; and if it be not violent,—if it be *muttering* delirium, then it is in proportion to the sinking of the patient, the fluttering state of the pulse, and the typhoid symptoms.

*Feigned Madness.*—It is of importance to know whether the disease is real or feigned. If it be feigned madness, the impostor cannot keep himself awake; as madmen frequently do. Madmen frequently sleep regularly; but frequently they can do without sleep for a long time; but, where the disease is feigned, persons cannot hold out. Neither can they desist from eating and drinking, as madmen frequently can; and the pulse is frequently not affected;—at least if they are confined, so that they cannot gain access to stimuli. Madmen will rave for days and weeks, without stopping; whereas a person who is feigning madness, generally thinks it necessary to rage violently, because he considers it an important feature of insanity; and the consequence is, he cannot continue it. Supposing, however, that the patient does not affect *mania* (that is to say, *general* insanity, derangement on all points), but *monomania*,<sup>a</sup> he generally overdoes it. It is impossible to convey, by words, an accurate idea of what we mean; but generally there is some over-acting, or some sort of inconsistency. He does not support the character well. He is not aware of all which he ought to do; and he does more than he should.

*Concealed Madness.*—There is no difficulty, therefore, in establishing the diagnosis;—as to whether it is phrenitis, or fever, or insanity; or whether it is a case of feigned insanity or not. The difficulty is to ascertain whether a patient is *really* mad, when he pretends *not* to be so. The difficulty is not to prove cases of “*morbi simulati*;<sup>b</sup>” but cases of “*morbi dissimulati*;<sup>c</sup>”—not where the disease

<sup>a</sup> See Page 549.

<sup>c</sup> “Concealed diseases.”

<sup>b</sup> “Pretended diseases.”

is pretended; but where the patient pretends not to have it. I formerly alluded to some cases, which showed how cunning madmen were;<sup>a</sup>—how necessary it is to take them by surprise;—to ask circuitous questions; so that they may be led to the main question, without being aware of it.

*Prognosis.*—If there be hereditary tendency to the disease, or if there have been an injury of the head, or if there be a peculiar organization of the head, or if there have been previous attacks of the disease,—recovery is not the less probable, but relapse is the more probable. Such persons do not less easily recover than others; but when they *have* recovered, they may easily fall into the disease again. I believe that the prognosis is rendered more favourable by the individual, in whom the disease occurs, being neither very young, nor in an advanced life; but in the middle period of life. The more violent the exciting cause, the more favourable will be our prognosis; because, if the exciting cause be very slight,—if a small spark have excited a great flame, it may be supposed that the person is strongly disposed to insanity; whereas, if the exciting cause be very violent, there was probably but little disposition to the disease; but the violence of the cause was every thing.

Mania,—general excitement of the brain,—general delirium,—general violence of feeling, affords a more favourable prognosis than *monomania*. Mania is a general disturbance of the whole head; and it is more capable of correction than a fixed disturbance on one point. It appears to be more of the nature of the inflammatory state of the brain; and inflammation is more easily recovered from, than any thing locally fixed,—where the patient dwells upon some one particular point. Dementia, or that weakness of intellect which follows insanity, affords the least favourable prognosis; for the brain is generally in such a state of inexcitability, that it seldom recovers its power. If a person have epilepsy, or other diseases of the nervous system, recovery is rare. The longer the disease has existed, the less chance is there of recovery; the more acute the disease, the more transient (in general) it is. With regard to those cases which occur in a puerperal state,<sup>b</sup> recovery is more frequent than otherwise. The prognosis may generally be given favourably, when the patient has fallen into the disease after delivery, or during suckling.

### *f. Treatment of Insanity.*

The *treatment*, like the *causes* of insanity, is generally divided into two kinds,—*moral* and *physical*; and the physical, again, are divided into two kinds,—first, *antiphlogistic* measures; and, in the next place, *soothing* measures.

#### *1. Physical Treatment.*

*Antiphlogistic Measures.*—When the case is recent, and there are phrenitic symptoms, the remedies for inflammation within the head are to be adopted, with more or less vigour; or when the case is *not* recent, but we have similar symptoms during any period of the disease, the same measures are to be more or less adopted. Generally speaking, however, antiphlogistic measures are not very admissible. When blood is taken away, it is found, in the greater number of cases, that it is neither buffy nor cupped; and the majority of cases treated actively, as phrenitis, do not turn out so well, as those in which such treatment is not adopted; or in which such treatment is adopted with very great moderation.

I have before mentioned<sup>c</sup> that, in insanity, there may be no signs of phrenitis at all; or that if there be, still the mental aberration, and the mental excitement, are out of all proportion to the signs of inflammation which exist. I stated<sup>d</sup> that the disease is not inflammation of the brain; for, though there may be more or less of an inflammatory state, yet that does not explain the disease. It is a morbid state,

<sup>a</sup> See Pages 552 and 559.

<sup>b</sup> See Page 572.

<sup>c</sup> See Page 574.

<sup>d</sup> Ibid.

not necessarily of an inflammatory nature; and that morbid state, although frequently *connected* with inflammation, is unquestionably not *founded* upon it.

*Blood-letting.*—In the beginning of the disease, however, very frequently a certain extent of blood-letting is proper; together with a certain degree of purging and pyalism. For example:—the exhibition of tartar emetic, in large doses,—so as to produce a state of nausea, and depression of the system,—may be serviceable. But we must be guided, in the employment of these measures, by the state of the patient; by the recency of the occurrence; by the state of the constitution at large; and by the strength and character of the pulse. We must remember that, whatever signs of inflammation there may be, the disease is not necessarily of an inflammatory character; and that it is much better to adopt moderate antiphlogistic measures, such as will not greatly depress afterwards.

*Cold to the Head.*—Among these, the application of cold to the head is one of the best. The application of ice is often much more effective than bleeding; and it is not attended by such subsequent depressive effects as bleeding. I can lay down no rule for the adoption of antiphlogistic measures, except this;—that we must be very much on our guard, and not trust too much to bleeding. When the disease has existed for any considerable time, if a fit of violence come on, it is very rarely to be treated by blood-letting; but cold must be applied; and we must remove, as much as possible, all stimuli.

*Stimulants and Narcotics.*—However, we have sometimes a very different state from that of inflammation. Frequently there is great aberration of mind; but, while the mind is in a state of high excitement, the pulse is of a weak character,—perhaps very rapid; and it is clear, from the whole state of the patient, that we must not adopt depressing measures; but that, on the other hand, stimulants and narcotics are the most useful. Frequently, in this disease, there is a weakness of pulse; which easily proves, to an experienced person, that the case is one, not of inflammation, but of irritation. This is to be treated by cold;—in the form of ice, or cold water, or a shower-bath; and frequently by good nourishment, and narcotics. Cold lessens the morbid irritability of every part of the body.

*Both Plans Conjoined.*—Now and then, both plans may be very moderately conjoined;—just as in the treatment of inflammation. But frequently maniacal patients are in such a state of excitement, that they will not bear more than the application of ice to the head, and moderate purging; and we may find benefit by the administration of a certain portion of wine; or (what generally answers still better) a certain portion of porter, or good strong malt-liquor of some other kind; together with nutritious food. As to narcotics, morphia has been found of late to answer much better, in a great number of cases, than opium. I have seen persons soon sent to sleep, in this state, by a large dose of camphor;—a scruple of camphor given every three or four hours.

It is necessary, not only at the *beginning* of the disease, but at its *crisis*, to prevent the patient from falling into an inflammatory state of the head; and, on the other hand, it is necessary to keep up the strength;—not to allow him to sink into a state of debility and irritation. Moderate antiphlogistic measures are the only ones to fulfil the former indication; and nutritious food, or even the moderate administration of stimuli, together with narcotics, are very serviceable for the latter.

*Attend to other Diseases, if present.*—I need not to say it is necessary, in all cases, to remedy any other disease that may be present. If there is costiveness, vomiting, chronic hepatitis, or any other disease, get rid of it if possible; for, in most instances, it will only exhaust the patient so much the sooner; and in fact, irritation in *one* organ, frequently keeps up irritation in *another*. Now and then cases occur, in which mania is suspended by the production of another disease; but these instances are comparatively rare. If the new disease were but slight, (supposing, for example, it were only the itch,) it might be well to let it run its course; but if there were any serious disease, I should consider it our duty to cure it; at any rate, to lessen it as much as possible; because the insanity itself could not do more mischief than it will.

*Support the General Health.*—Not only is it necessary to remedy any diseased state that may exist,—unless it be clearly beneficial to the mind, and at the same time clearly not injurious to the body,—but it is also necessary to support the health as much as possible;—to have the patient, as much as possible, in the fresh air; to observe the most perfect cleanliness; and to take care that all his food shall be of the best quality.

*Warm and Cold Baths.*—Warm and cold baths are found very useful; but it is in melancholia that warm baths answer best. The cold bath, in most cases of insanity, when patients glow after it, is an exceedingly useful measure; and in violent paroxysms, a cold shower-bath, continued till the patient is pretty nearly overpowered, has often a beneficial influence. As a means of remedy in chronic cases, also, the shower-bath is one of the best things that can be employed.

A hot and a cold bath have been sometimes had recourse to together. If the patient be placed in a hot bath, and after a short time a stream of water be allowed to play on the head,—descending for about three feet, till the head be thoroughly cold,—it is said to be very beneficial. These are all various modes of effecting the same purpose.

*Means for subduing the violence of the Paroxysms.*—Speaking of the remedies for the purpose of subduing great violence, I may mention that the most violent fits of insanity,—the greatest paroxysms of rage will, in general, cease for a time spontaneously. It was the custom of Pinel, the celebrated French physician, to let patients exhaust themselves;—to let them rave away; being certain that, after a time, they would be quiet again. Nature is exhausted after great excitement; for the latter cannot be carried on for a long time. But, for the purpose of suppressing this violence, when it is too long continued, some practitioners have recommended a rotary machine; in which the patient is set upright, and spun round as fast as possible;—till he is sick and giddy, and reduced to quietness. In that way a maniac, like any body else, will be rendered pretty calm. It has been recommended to lay the patient horizontally, with his head at the centre, and to spin him round in that position; so that the blood might be driven from the head to the centre of the body, by the centrifugal force. I have seen it put in practice in lunatic asylums abroad; where the patients spun round as fast as a tetotum; and, it is said, with the effect of quieting them.

## 2. Moral Management.

With regard to *moral* management, very great good may be effected. The *medical* treatment is, for the most part, adopted for the purpose of lessening any urgent symptoms at the time; and for the purpose of preventing mischief; but with regard to curing the disease, I believe physical treatment, in the greater number of cases, is not very efficacious. We may do great good by means of it;—we may prevent an inflammatory state of the head; we may support the constitution; we may do great good by cooling the patient, procuring sleep, maintaining the general health, removing diseases in other parts of the body, re-exciting a suppressed discharge, preventing additional mischief, and lessening urgent symptoms. The *moral* treatment, however, is of the very highest importance.

*Cultivate the Healthy Faculties.*—In the first place, it is right to cultivate any faculties that are still sound. If patients be not *universally* insane, but have any mental faculties left in a state fit for occupation, it is exceedingly serviceable to employ them. If a patient have a taste for drawing, for music, for mechanical contrivances, or for any other employment, that faculty should be cultivated. He should be allowed to make the best exertion he can with his intellect. A pleasurable occupation of this description, is exceedingly advantageous;—not only as contributing to the happiness and the comfort of the patient, but as withdrawing him from insane ideas. By this means persons have frequently had their insanity very easily subdued.

*Moderate Exercise.*—It is also found, almost universally, of great service to

enjoin moderate exercise. A large number of maniacs, who have no intellect left for any pleasurable mental occupation; and many who, even while in their senses, knew not what intellectual delight was,—may still derive great pleasure, as well as great improvement of health, from bodily exercise. Nothing is found more useful, in the treatment of lunatics, than to give them things to do, and, more especially, to make them work in gardens; and occupy themselves continually, in the open air, with bodily exercise.

*Interest the Feelings.*—It has also been found of great use, not only to maintain activity of body, and cultivate those faculties of the mind which are still entire;—to make the most of what is left; but also to interest the feelings. This has been found particularly the case with females. We should give them animals to take care of; for the tender feelings are excited, and a constant interest is kept up by having animals under their care. This has been found, in many instances, of very great use. Whatever their station in life may be, by giving them bodily exercise, we maintain the general health; we withdraw their attention from madness to reason; and, in some degree, create a pleasant state of mind. This may be done by mental occupation, as well as by bodily exercise. One great point is, to produce a pleasurable state of excitement; and, in conformity with this, it is necessary to make them as happy, in all respects, as possible;—to treat them with the utmost kindness;—never to have recourse to severity, except in urgent cases; and never to have recourse to harsh punishments, or to any thing which can border on cruelty.

*Impropriety of Harsh Treatment.*—Nothing should be done which is calculated to irritate their mental or bodily feelings;—to inflict corporeal pain, or produce vexation of mind; unless the latter be absolutely necessary. No stripes, or corporeal punishment, ought ever to be adopted. Formerly, straps and bars were had recourse to, as a proper mode of treatment. Till modern times, the chief treatment of insanity consisted in cruelty. Celsus gives direction for the employment of the greatest severity towards lunatics.<sup>a</sup> Meibomius (after whom the tarsal glands are named) says that Rhazes, an Arabian physician, orders that when a person labours under “love-madness,” and nothing else will do, he must be tied up, and then soundly thrashed, and beat well with the fists; and this again and again. “One swallow does not make a summer;” and therefore, if one thrashing does not do, give the patient another. Another writer agrees with him; and says—“If the patient be a young man, let his posteriors be well flogged; and, if he be not quiet then, put him into the bottom of a tower, with some bread and water, till he begs pardon for being mad, and becomes sane.” Such were the ideas entertained, formerly, of the treatment of insanity.<sup>b</sup>

*Restraint, when Necessary, should be Mild.*—There should be the mildest restraint possible. Restraint is sometimes very necessary; because some patients are mischievous; and they will not only tear things to pieces, and do all the mischief they can; but they will murder themselves or others. But restraint, when

<sup>a</sup> Celsus, however, is by no means an unqualified advocate of harshness; for (in Book 3, Chapter 18) he says—“*Sæpius tamen assentiendum, quam repugnandum est; paulatimque, et non evidenter, ab his quæ stultè dicuntur, ad meliora mens adducenda. Interdum etiam elicienda ipsius intentio; ut fit in hominibus studiosis litterarum, quibus liber legitur, aut rectè, si delectantur, aut perperam, si id ipsum eos offendit; emendando enim convertere animum incipiunt. Quin etiam recitare, si qua meminerunt, cogendi sunt. Adcibum quoque quosdam non desiderantes reduxerunt hi, qui inter epulantes eos collocarunt.*” —“Yet we are oftener to agree with their opinions, than to oppose them; and by this means the mind is (by degrees, and insensibly) to be led from a foolish to a better mode of discernment. Sometimes, also, an effort of the mind is to be elicited,—a plan which is adopted with literary men; to whom a book is read, correctly if it please them, or incorrectly if such improper reading displeases them: for they then turn their attention to correcting it. Moreover, they should be urged to recapitulate whatever they may remember. Some, who had before no desire for it, have been induced to partake of food, by being seated with those engaged in eating.”

<sup>b</sup> This “love-madness” (observes Dr. Elliotson) is certainly the only case in which such treatment should be adopted;—if adopted at all.

necessary, should always be effected in the gentlest manner. At those lunatic asylums where the greatest attention is employed, there (I believe) the greatest gentleness is found admissible; for the more cruelly we behave to lunatics, the worse they are. It is in mismanaged lunatic asylums, that we have shouting and howling; and that every kind of trouble is experienced. Where the keepers of lunatic asylums are benevolent,—use no more restraint than is necessary; and especially use restraint in the least offensive manner; and where they take every admissible opportunity of being kind to the patients;—there we find the patients nearly all quiet; and a very small number indeed require corporeal restraint.

If punishment be necessary for having done amiss, patients ought not to be flogged, but confined for a day;—as a child would be; and should be told that that is the punishment for having done amiss. It is certainly right to be firm in all this;—never to threaten punishment, and then not put it in execution. A maniac would soon find out this mistaken lenity, and take advantage of it. Whatever is threatened, should be put into execution;—provided we threaten nothing but what is right; so that maniacs may depend upon punishment, as a certain consequence of misconduct. But the utmost that is required in the way of punishment, is to deprive them, for a little time, of any pleasure which they are accustomed to have, or to employ a little more restraint than usual.

*Removal of Knives, &c.*—In the next place, it is very necessary that there should be nothing dangerous allowed to be in the patient's reach;—knives, or any instrument of which the patient might make a bad use. There are various degrees of insanity; and many patients may be trusted with things that might do harm; but, as a general rule, every thing with which he could do mischief, should be removed from a patient's reach. The windows should be well secured; and the patient should have no opportunity whatever of doing mischief; for lunatics are very sly. Bars, however, should be so placed before the window, as to look ornamental, rather than otherwise; and so as not to give the idea of a prison-house.

*Separation from Friends.*—There should be nothing about the individual, to remind him of the circumstances connected with his insanity. Hence, in most cases, it is found useful (as a general rule) that the patient should be removed from his friends; for the circumstances connected with his insanity will (of course) present themselves, if the patient see his friends frequently, or remain in his own house. It is, for the most part, advantageous to take the patient away from his friends, and his own premises; in order that all associations connected with his insanity may be removed.

*Interviews with Friends.*—Still, although it is necessary to remove patients from their friends, yet when reason is returning, it has sometimes been found useful to gratify them with a sight of those they love the most. I know that exceptions to the rule of not allowing them to see their friends are rare; but now and then that rule may be broken through, and great advantage be derived from such a breach of it. Dr. Gooch, in the “*Transactions of the College of Physicians*,”<sup>a</sup> and likewise in one of his posthumous volumes,<sup>b</sup> gives an account of a lady with puerperal insanity; in whom the gratification of seeing her husband, was apparently productive of good effects. It was an experiment; but Dr. Gooch satisfied himself that it was likely to be productive of benefit. It is a good general rule, not to be broken through without care; but the result, in Dr. Gooch's case, was very satisfactory.<sup>c</sup>

<sup>a</sup> Volume 6; Page 294.

<sup>b</sup> “Account of some of the Most Important Diseases peculiar to Women.”

<sup>c</sup> A lady, twenty-eight years of age, of good constitution, but susceptible mind, became affected with melancholia, a few months after her second lying-in. Toward the end of her pregnancy, a frightful incident had occurred to a near relation; and affected her so deeply, that she often spent the night sleepless, sitting up in bed, thinking of her misfortune, and dreading that she should lose her reason after her confinement. Having nursed her child without feeding it for three or four months, with much unnecessary anxiety and exertion, she grew thin and weak; complained of sinking at the stomach, and aching in the legs; and experienced so much confusion of mind, that she could not arrange her domestic accounts. She became low-spirited;—she knew not why. She was advised to wean her child, took some

A similar case occurred to me, some years ago, in a gentleman who had been deranged from moral causes. From great anxiety of mind, he was perfectly deranged; but his insanity subsided, and he told me that he should like to see his

light tonic and gentle laxative, and went down to the sea-side; but, at the end of a month, she returned home;—having derived little benefit from her absence. Her spirits became gradually more depressed; and it was impossible to persuade her that she had not some fatal disease. One day it was a cancer; another, inflammation of the bowels; and to such a height did her apprehensions rise, that her husband was often brought home, by some alarming message, and found her with a solemn air; and, in a low whisper, giving direction to her servants whom she had assembled around her, what to say if she should expire before her master arrived. She now grew much worse; and there was no longer any doubt about the nature of her complaint. She was seen by a physician of extensive experience in these diseases, and sent into the country. Many weeks passed: sometimes she was better, sometimes worse;—now accusing herself of the deepest depravity, and meditating schemes of self-destruction; then, again, convinced of the absurdity of her notions, and struggling against the load which for a short time every day weighed on her heart. In this way many weeks passed. At length, the disease came upon her with more violence than ever; and, in her self-examination and condemnation, she became quite ferocious.

She was now put under the care of an experienced attendant; separated entirely from her husband, children and friends; placed in a neat cottage, surrounded by an agreeable country (it was the finest season of the year); and visited regularly by her physician.

For several weeks she manifested no improvement. Sometimes she was occupied with one notion, sometimes with another; but they were always of the most gloomy description. At length it became her firm belief, that she was to be executed for her crimes, in the most public and disgraceful way. Every noise she heard, was that of the workmen erecting the scaffold; every carriage, the officers of justice assembling at the execution; but what affected her most deeply was, that her infamy had occasioned the disgrace and death of her children and husband, whose spirit haunted her. As soon as the evening closed, she would station herself at a window at the back of the cottage, and fix her eyes on a white post that could be seen through the dusk. This was the ghost of her husband; who, day and night, was whistling in her ears.

Several weeks passed in this way. The daily reports varied; but announced nothing happy. At length her husband became impatient; and begged to have an interview with her;—thinking that the best way to convince her he was not dead, was to show himself. This was objected to. He was told the general fact, that patients are more likely to recover when completely separated from their friends; and that if she saw him, she would say it was not himself, but his ghost: but the husband was obstinate; and an interview was consented to. When he arrived at the cottage, he was told that she had had a tolerable night, and was rather more tranquil; but that there was no abatement of her gloomy notions. "As soon as I entered the drawing room, where she usually spent the day," [I [Dr. Gooch] copy his own statement, and which he wrote down at the time of the occurrence,] "she ran into a corner, hid her face in her handkerchief, then turned round, and looked me in the face;—one moment appeared delighted at the thought I was alive; but immediately afterwards assumed a hideous expression of countenance, and screamed out that I was dead, and come to haunt her. This was exactly what Dr. Gooch had anticipated; and for some minutes I thought all was lost.

"Finding that persuasion and argument only irritated and confirmed her in her belief, I desisted; and tried to draw off her attention to other subjects. It was some time since she had seen me or her children. I put her arm under mine, took her into the garden, and began to relate what had occurred to me and them since we parted. This excited her attention: she soon became interested; and I entered, with the utmost minuteness and circumstantiality, into the affairs of the nursery, her home, and her friends. I now felt that I was gaining ground; and, when I thought I had complete possession of her mind, I ventured to ask her, in a joking manner, whether I was not very communicative for a ghost. She laughed; I drew her from the subject; and again engaged her attention with her children and friends. The plan succeeded beyond my hope. I dined; spent the evening with her; and left her, at night, perfectly herself again."

He went the next morning, in a state of intense anxiety, to know whether his success had been permanent; but her appearance at the window, with a cheerful countenance, soon relieved his apprehensions. While he was there, Dr. Gooch came in. He went up stairs, without knowing the effect of the interview; and came down, saying—"It looks like magic!" With a view of confirming her recovery, she was ordered to the sea-side to bathe. As soon as the day of her departure was fixed, she began to droop again; the evening before it, she was very low; and, on the morning of her setting-off, was as bad as ever. This state continued for several weeks, in spite of sea-air and bathing; and ceased as suddenly as it had done before;—apparently in consequence of interviews with friends, calculated to remove the apprehensions by which her mind was haunted. She has since then continued perfectly well; and has had another child, without the slightest threatening of her former malady.—*Gooch, on the Diseases peculiar to Women; Chapter 21. (Second Edition; Pages 163 to 168.)*

wife; for that it was very hard to be kept from seeing his wife and family. I found him still deranged; but I stopped with him two hours, and satisfied myself that it would do him good. He wished to leave his bed-room, and see different parts of the house. I took off his jacket, and led him down stairs; and gratified him by letting him see, first one part of the house, and then another. I watched the effects, and found it did not disturb him in the least. On the contrary, he seemed to gain intellect, and power over himself, as we proceeded. There were many little gratifications which he wished for, and which I let him have. One curious thing was to kill a *bantam-cock*, which he saw from a window; and which appeared to him as a spectre, or a fiend. The colours, he said, had been terrific to him; and he should not be happy till it was killed. I gratified him with it; and he was exceedingly thankful. He killed it himself. I watched him carefully, for some time after this; and at last I satisfied myself, that the sight of his wife would not be dangerous. I might have been wrong; but it turned out that I was right. I brought her from a neighbour's house; and the interview was most affecting. From that moment he was perfectly in his senses; except for a few days when he was violently excited, and then he was found to ramble. This rule of separating a patient from his friends, therefore, although a very proper one, may be now and then transgressed; but it should not be broken without extreme caution. For the most part, when patients are insane, if their friends be about them, it increases the general excitement; and there is no chance of doing any good, till they are withdrawn.

The absence of all corporeal punishment,—of all cruelty or severity,—of every thing which is calculated to irritate the patient, and the adoption of every thing that is mild, and gentle, and soothing, and calculated to excite their best feelings, and all their feelings in a pleasurable and satisfactory manner;—this will lead, very frequently, to the removal of the disease. But beyond this gradual operation on the disease, moral treatment cannot be expected to go. We cannot expect, by moral treatment, to cure a madman at once.

*Immediate Recovery by Moral Means.*—A story, however, is related, of a person being cured in France, all at once, by moral means. A madman maintained the possibility of the miracle of St. Denis. The miracle was, that the saint kissed his own head. A madman was maintaining that this was a fact; and said it was possible, because he had done so himself. Another madman inquired how he did it; and whether he kissed it with his heel;—and then he laughed at him. From that moment the man never spoke of it again. Now it is quite clear that the man must have been almost in his senses, to have seen the validity of any such reasoning.

Another is said to have believed himself the Holy Ghost; and he had a neighbour in the madhouse, who also believed that he was the Holy Ghost; and, as they were not far separated, they were brought to each other. The one inquired —“Can there be two Holy Ghosts? You say *you* are the Holy Ghost; and *I* am the Holy Ghost;—can there be two?” The man got up and said—“There cannot be two Holy Ghosts;—I must be wrong!”—and he never again called himself the Holy Ghost. But when such an effect as this is produced, the person must be almost well.

There was another man who fancied himself dead,\* and implored to be buried. He assured his attendants that he was quite dead; and he abstained from food, as a dead man ought to do: and was laid out, as dead men are. He was conveyed towards the church;—not enclosed in a coffin, but carried in a bed. His friends took care that some merry fellows should meet the funeral, at a certain part of the road. They asked who it was that was going to be buried; and the men who carried him replied, that it was a very bad fellow,—that the world had happily got rid of him. This so provoked the man, that he sat upright; and became so savage, that he jumped down to thrash them all. He was then taken home; sat down; ate a good dinner; and recovered from that time. This is another instance of a man

\* See Page 550.

who was all but well at the moment. It is not for such purposes as these, that moral treatment is to be adopted. We *may* do good in such cases as these; but, in general, such a result is not to be expected.

*Stratagem sometimes Necessary.*—It is very necessary to have recourse to stratagem in many cases. There was another instance of a man<sup>a</sup> who fancied himself dead, and would not eat; and, as there was a fear that he would die of starvation, the following stratagem was adopted. Some people<sup>b</sup> dressed themselves in shrouds, like corpses; and went into his room, which had been previously darkened. These people carried food with them, and ate of it freely; saying that they were dead, and the dead always ate well; and, as he wished to do every thing that became a gentleman who was dead, he thought he would eat too. It is said that he then fell asleep; and that when he awoke his fancy was gone.<sup>c</sup> Another person would eat, but he would not be *seen* eating; and this is very common. Some madmen will not eat in the presence of any body; nor will they eat if they think any one will discover that they have been eating. A madman who had such a whim, had food given him; with a request that he would feed the cat with it. He was extremely hungry, and ate it very readily; and afterwards declared that he had given it to the cat, who swallowed it down all at once.

*Regularity in the Performance of Daily Functions.*—One point is very necessary to be attended to. If we make insane people do every thing with regularity, there is far less trouble with them, in the way of eating and drinking, sitting up, and going to stool. A certain hour should be fixed for all these purposes. Nothing is found more useful, in the treatment of insane persons, than to establish habits for every thing which we wish them to do. If a certain hour be established for going to the water-closet, they will go as a matter of course, without ever thinking of staying away, and retaining the contents of their bowels; whereas, if there be no fixed time for it, we may have the greatest difficulty. So with respect to food, and every thing else.

<sup>a</sup> Henri-Jules de Bourbon; the first prince of the house of Condé.

<sup>b</sup> His valets, Girard and Richard.

<sup>c</sup> During the last twenty years of his life, he was frequently subject to fits of hypochondriasis. In these fits, he would utter the strangest things imaginable; and act, in every respect, like an insane person. In his last journey to Burgundy (of which he was governor), for instance, he fancied himself a hare; and ordered the bells not to be rung;—lest they should frighten him, and compel him to take refuge in the woods. He once fancied himself a plant; and, as such, ordered himself to be watered. For this purpose, he placed himself in the garden of the Hotel Condé; and insisted on being watered by M. de Plainville, one of his pages. This page, however, was unwilling to perform so strange an office; and, leaving the two watering-pots full of water, that he had brought, made his escape, and hid himself. His royal highness was filled with indignation at the page's disobedience; and threatened worlds of mischief in retaliation. The threats, however, died away, as the fancy lost hold of his imagination. One of the most frequently occurring of his mental delusions, was the belief that he was a bat; and he actually caused a room to be hung with stuff, and wadded;—for fear he should fly against the boards in the day-time, and do himself some injury. An hour before his dissolution, he ordered a couple of stout sticks to be brought to him. At a loss to imagine what he could want sticks for at such an awful hour, they were tremblingly brought to him; when, having caused them to be placed on either side of him on the bed, he called for the princess, and Mademoiselle de Langeron. These ladies being apprised of his royal highness's wish to see them, (not, however, without being first warned to beware of the sticks,) with doubtful feelings made their appearance. When the prince saw them, he said that, considering the shameful way in which he had treated them during his lifetime, he deserved that they should retaliate upon him; and begged that they would make him die under the blows they would minister to him with the two sticks. The poor prince, however, was saved such a death; for he died before he could persuade his wife to take one of the cudgels.—*Extracted from the "Mémoires du Comte de Maurepas;" in the "Mirror of Literature;"* Volume 33, Pages 314 and 315. (No. 949; May 18, 1839.)

## CHAPTER VII.

## AFFECTIONS OF THE SPINAL CORD.

[HAVING, in preceding chapters, considered those affections, which are seated solely in the brain, and are characterized by a disturbance of the functions of sensation, judgment, and volition,<sup>a</sup> we will now proceed to another class of affections; mainly distinguished by the presence of spasm or convulsion on the one hand, or paralysis on the other. Recent investigations into the physiology of the spinal cord, have shown that these affections consist in the derangement of functions belonging, exclusively, to a system of which the *true spinal cord* constitutes the centre. It is desirable, therefore, to point out the distinguishing features of the two systems.

“The functions of the cerebral system,—sensation, perception, judgment, volition, and voluntary motion,—are gradually developed from infancy to adult age. It is the *ψυχή*,—the ‘animus,’—the ‘soul,’ enthroned on an organization, which gradually becomes more and more perfect. These functions are *psychical*. How different from those of the true spinal or mere excito-motory system! By the former we *feel* external impressions, *perceive* external objects, judge of their properties, *wish* and *will* to approach and avoid them, and actually *move* (by a *voluntary effort*) to or from them. By the latter, when an external object induces an appropriate action in certain muscles, its ingestion into the animal frame is effected or prevented, without any cognizance of our mind or will; although sometimes with such concurrence shown by additional voluntary acts. Thus, the atmospheric air is inspired, while carbonic acid is excluded, without any voluntary, cerebral, or psychical act; the sphincters still act, when the organ through which the soul manifests its faculties is removed.

“Cerebral diseases affect primarily the cerebral functions, and the true spinal functions consecutively. The diseases of the true spinal system induce changes in the excito-motory phenomena in the first place, and in the cerebral functions in the second. Cerebral diseases are generally more insidious in their progress, than the true spinal; because slight aberrations of the cerebral functions are less observable than similar affections of the true spinal system;—pain, vertigo, watchfulness, &c., being less striking than the slightest degree of convulsive movement or paralytic affection. It is on this account that the *first* symptom *observed* in cerebral disease, is frequently one belonging to the true spinal system; especially *vomiting*, perhaps *strabismus*.

“The true spinal diseases, especially those of eccentric origin, affect in a remarkable manner the functions belonging to this system;—those of the eye and eyelid; those of the larynx and pharynx; the respiration; the action of the expulsores and sphincters; and that state of the muscles designated by the term ‘*tone*.’ We must revolve in our minds the symptoms of epilepsy, of hysteria, of tetanus, and of hydrophobia; the causes and phenomena of vomiting, of asthma, of abortion, of tenesmus, and of strangury; and we shall be forcibly struck with the justice of this remark.

“In many diseases the influence of the excito-motory power, and of the passions, over acts of volition, is most obvious; as is also that of volition over excito-motory power. Let the patient in chorea be directed to move his hand in a given manner; we shall immediately observe the distorted movements produced by the disordered agency of the excito-motory power. Let the patient be agitated, and

<sup>a</sup> Phrenitis (Page 481); Hydrocephalus (Page 500); Apoplexy (Page 512); Mental Shock (Page 530); Delirium Tremens (Page 531); Tumours in the Brain (Page 536); Affections of the Intellect (Page 533).

his chorea is tenfold worse than before. The disordered action of chorea, are also aggravated by every act of the will; they subside, on the contrary, during sleep. On the other hand, every convulsive effort affects the brain with congestion and its consequences; of which a fatal coma, or effusion, is not the least frequent.”<sup>a</sup>

We shall now proceed to consider the various affections of the cord itself; commencing with “Spinal Irritation.”]

## SECTION I.—SPINAL IRRITATION.

*Definition.*—[‘This term has been used to designate an affection usually characterized by pain in the back; either induced or increased by pressure of the spinous processes of the vertebræ, accompanied by neuralgic and hysteric symptoms, of a nature so variable as to simulate almost every form of disease to which the body is liable. Spinal irritation ought to be considered rather as an effect of disease, than as a malady *sui generis*; but, as the subject is of the highest practical importance, it is proper to direct attention to it, by giving a detail of its phenomena in this place.

*Symptoms.*—The phenomena this affection presents, differ according to the extent, seat, and intensity of this irritation; and are so greatly diversified as to prevent the possibility of giving a description that would be applicable even to the majority of cases. The only means we can think of for conveying a general idea of this disorder, is by referring to the different forms of hysteria, neuralgia, and chronic rheumatism. A combination of the symptoms occasionally presented by all three, constitutes spinal irritation.

The only constant symptom, is more or less pain on pressing the spinous processes of the vertebræ. It may be confined to one spot, or be more or less diffused over the spinal column;—pointing out the extent of the spinal irritation. In many cases the patient is unconscious of any thing wrong in the back, often denies the existence of pain in that situation, and refers all the uneasiness to the ultimate distribution of the nerves arising from the part. Sometimes there is a dull constant pain; which is overlooked, and thought to be wholly unconnected with the local complaint. When pressure is made on the affected part, however, the pain in the back is increased; and not unfrequently the patient starts as if an electric shock had been received, or falls into a state of syncope. The seat of pain generally corresponds with the origin of the nerves ramifying on the organs, or portion of the surface complained of; although in some instances, as stated by Griffin, the morbid changes in the cord appear somewhat more extensive than the external tenderness. The local pain is often produced or increased by lifting heavy weights, or twisting the body; and has often been excited by jerks or slight concussions when walking.

In conjunction with the spinal tenderness, there may be neuralgic pains (more or less diffuse) over different parts of the surface, diminished sensibility, convulsions, or paralysis; and, as the functions of the different viscera and organs of the body are often impaired, various diseases are simulated. Thus women suffer neuralgic pains sometimes in the right, but more commonly on the left side, beneath the mamma; sometimes, again, the breast itself is more especially affected;—constituting the “irritable mamma” of Sir A. Cooper. In other cases there is a feeling of numbness,—as pointed out by Dr. Brown of Glasgow; or of constriction round the thorax;—as if a walnut, or other hard substance, were pressed within a tight belt. Occasionally the affection commences with pain in the occiput, and rheumatic sensations in the neck and shoulders; several cases of which are given by Mr. Teale of Leeds. At other times, instead of neuralgic pains, there is a sense of numbness in the hands or feet; extending more or less over the extremities.

<sup>a</sup> “Diseases and Derangements of the Nervous System. By Marshal Hall, M. D.” Chapter VI.

We have seen a case where the only symptom was excessive coldness in the hands and fingers, that often amounted to actual pain; and prevented the individual from sewing, and carrying on her usual employments. If the spinal irritation be more severe, the internal organs participate; and the symptoms produced vary according to the portion of the cord that is affected.

When the spinal tenderness is confined to the cervical portion, there may be headache; loss of voice; neuralgic pains in the face and gums; trismus; various disorders of vision (as ocular spectra, *muscæ volantes*, night-blindness, &c.); more or less deafness, or confused sounds in the ears; diminished or perverted sensation of taste and smell; dysphagia; paralysis of the tongue; sickness; vomiting; loss of appetite; inordinate hunger or thirst; pain at the stomach; pyrosis; difficult breathing; cough; irregularity of the pulse; palpitations; disposition to syncope; paralysis of one or both arms (sometimes confined to the fingers, hands, arms, or shoulders); increased sensibility or numbness in those situations; pricking, formication, &c. Although these symptoms may have coincided at different times with cervical tenderness, it is evident that many of them—more particularly such as affect the special senses—arise from irritation of the cranial portion of the cord. When vertigo or delirium is present in such cases, it is probable that the brain itself is more or less affected. When the irritation is in the dorsal region, the dyspnoea and palpitations of the heart are more marked; there is sometimes dry cough; pleurodynia;<sup>a</sup> pain under the clavicles, in the shoulders, and in the superior extremities; sense of constriction in the thorax (often like a tight band); neuralgic pains in the side: diminished sensibility in the breast and epigastrium; more or less derangement in the digestive organs; &c. When it is situated in the lumbar portion, the symptoms are,—pain in the parietes of the abdomen, hypogastrium, loins, and genito-urinary apparatus; symptoms resembling gravel in the kidneys, ureters, or bladder; irritable uterus; cramps and increased sensibility, or palsy (more or less complete) in the inferior extremities.

When the spinal irritation is more diffused, there is an admixture or combination of the above symptoms. Hence the occasional difficulty experienced in tracing the various undefined symptoms to their true source. Cases of angina pectoris, asthma, different form of neuralgia and hysteria, spasmodic croup, convulsions, hydrophobia, epilepsy, tetanus, chorea, paralysis, spasmodic colic, diarrhoea, cholera, irritable bladder, &c., are recorded by Griffin; all of which have been connected with the spinal irritation, and disappeared on its departure. It often happens, that the spinal tenderness shifts its position; when the other symptoms change also. Griffin details a remarkable case of a young lady, in whom the symptoms successively assumed the appearances of organic lesion of the lungs, heart, and abdominal viscera; together with an endless variety of other complaints of a neuralgic, asthmatic, epileptic, cataleptic, and paralytic nature. Indeed, the singular changes the disease undergoes, render it impossible to obtain a perfect knowledge of its numerous forms, without studying in detail the extraordinary cases which have been recorded of it.

*Causes.*—Women are much more predisposed to this complaint than men; and young girls more than married women. Of one hundred and forty-eight cases given by Griffin, twenty-six were males, forty-nine married women, and seventy-three girls. In a table of one hundred and fifty-four cases (given in the same work), we have determined that one occurred at the age of four years, that there were seven between the age of ten and fifteen; eighteen between fifteen and twenty; thirty-one between twenty and twenty-five; fifteen between twenty-five and thirty; seventeen between thirty and thirty-five; eighteen between thirty-five and forty; fourteen between forty and forty-five; twelve between forty-five and fifty; seven between fifty and fifty-five; three between fifty-five and sixty; five between sixty and sixty-five; and six whose ages are not recorded.

This disorder, therefore, is most frequent between the ages of fifteen and fifty;—

<sup>a</sup> From *πλευρον*, the side; and *οδυνη*, pain.

the menstrual period of women. Spinal irritation has been observed in every habit and constitution;—in the full and plethoric, as well as in those who are spare and delicate. In almost all who have been affected, however, somewhat of the nervous temperament has been remarked, or at all events a peculiar excitability of the system. The most common *exciting* causes are uterine disorder; exposure to cold and moisture; dyspepsia, worms, and other sources of irritation in the alimentary canal; affections of the liver; mental emotions; erysipelatous, rheumatic, and eruptive fevers; local injuries, &c.

*Nature.*—As spinal irritation, uncomplicated with other disease, rarely terminates fatally, the exact anatomical characters of this affection are unknown. There can be little doubt, however, that in the majority of cases the symptoms are referable to a state of congestion of the spinal cord or its investing membranes. Ludwig and J. P. Frank have alluded to the effects of spinal congestion, and the anatomical circumstances which favour its occurrence. The latter, in particular, has pointed out the absence of valves in the spinal vessels; together with their peculiar distribution on the surface of the cord. Their anatomical structure and arrangement render them peculiarly liable to congestion; as the venous blood must ascend in opposition to gravity. They are also equally pressed on by the cerebro-spinal fluid in a state of health; and any cause which tends to increase or diminish its normal quantity, may readily be conceived to produce venous congestion. Hence, derangements in the menstrual function, and the various causes which have just been mentioned, frequently occasion dorsal and lumbar pains; with other symptoms of spinal irritation. The vessels, being principally superficial, unless very much dilated, occasion only partial pressure; and consequently increased action, followed by the principal phenomena of this affection; namely, neuralgic pains. That motion is not so commonly increased or diminished, may be attributed to the relation of the cord with the osseous walls which surround it,—as pointed out by Ollivier; for the *anterior* columns are almost immediately applied to the bone, while the *posterior* are five or six lines distant from it. Independently of any positive evidence, therefore, it may be said that the theory of congestion is fully capable of explaining the phenomena, and is the morbid condition which of all others we should expect to follow the known causes of the disorder. On the other hand we cannot, with some authors, suppose it to be chronic inflammation; for the changeable nature of the affection, and its sudden appearance and disappearance, are opposed to such an opinion. With regard to the spinal tenderness, it has been well pointed out by Mr. Loeck, (“*Edinburgh Medical and Surgical Journal*,” No. 136,) that “an inspection of the vertebral column, in an anatomical subject, will show at once how impossible it is to press the cord or the nerves going from it, in the slightest degree.” We cannot think with him, however, that “tenderness of the spinal marrow is a sign of little value;” as numerous cases prove, that there is a connection between the situation of the local tenderness and other symptoms; while local treatment has dissipated the disorder, when remedies directed to the removal of its more remote effects have failed. No doubt the spinal irritation is in itself only a symptom, although one which indicates with tolerable certainty the origin of the malady; and, as our pathological knowledge improves, there is every reason to suppose that this view of its pathology will be generally admitted.

*Diagnosis.*—It is remarked, by the Messrs. Griffin, that there does not appear to be any complaint to which the human frame is liable,—whether inflammatory or otherwise,—which may not occasionally be imitated in disturbed states of the cord; and hence it is a prolific source of those complaints called “hysterical” or “nervous.” The same authors have given the following diagnostic symptoms, by which it may be distinguished from organic disease:—1. The pain or disorder of any particular organ being altogether out of proportion to the constitutional disturbance. 2. The complaints, whatever they may be, usually relieved by the recumbent position; always increased by lifting weights, bending, stooping, or twisting the spine; and, among the poorer classes, often consequent to the labour of carrying heavy loads; as in drawing water, manure, &c. 3. The existence of

tenderness at that part of the spine which corresponds with the suffering organ.

4. The disposition to a sudden transference of the diseased action from one organ or part to another, or the occurrence of hysterical symptoms in affections apparently acute. Attention to the four circumstances above enumerated, will generally enable the practitioner to identify this disorder. It may readily be mistaken for disease of the vertebral bones; as there is not unfrequently an apparent prominence of the vertebræ, where the tenderness is felt. As such an error may lead to very distressing consequences, it will be well to enumerate the circumstances which distinguish the one from the other. In vertebral disease, the prominence is angular, and depends on displacement of the bones, or curvature; in spinal irritation it is round, and is occasioned by slight swelling of the ligaments or coverings of the spine; in diseased vertebra there are seldom hysterical symptoms in young females, whereas they are common in spinal irritation. Disease of the vertebra is most common in young persons of a strumous constitution; whereas spinal irritation is most frequent in adults. Lastly: complete paralysis is common in vertebral disease, but rare in spinal irritation; and, in the latter, the general health is not so much affected.

*Prognosis.*—The prognosis in spinal irritation is always favourable; as there is every reason to believe, that the mere state of irritation uncomplicated with a more serious morbid lesion, has never proved fatal. When there is any other coexisting disease, the prognosis (of course) is the same as that of the particular affection with which the spinal irritation is complicated.

*Duration.*—The duration of the symptoms is very variable;—from a single day, to three or four years. A case is given by Griffin, where it continued four years and a half. According to his experience, a quick and irritable pulse, and furred tongue, are indications of an obstinate and troublesome attack.

*Treatment.*—The various and often contradictory symptoms, induced by spinal irritation, render its diagnosis and treatment difficult and uncertain. Numerous facts, indeed, attest that individuals have long laboured under rheumatic, neuralgic, and hysterical complaints; during which they have suffered the greatest tortures; although they have been relieved in a few days, by treatment directed locally to the spine. Whatever difficulties, therefore, may exist in drawing a line of demarcation between the effects of spinal irritation and numerous other disorders, and notwithstanding the obscurity that rests on the precise nature of the morbid change which produces it, the great practical utility to be derived from its study is unquestioned. So fully are we impressed with its importance, that we consider that, in all cases of neuralgia, rheumatism, and hysteria, the spine should be examined; while, perhaps, there is scarcely a functional disorder to which the young female is liable, which may not occasionally be found connected with spinal irritation. We have often had an opportunity of observing the manner in which numerous disorders have been traced to this source; and feel assured that if practitioners in general would pay greater attention to this complication, many of the extraordinary and anomalous cases which are at present the cause of great embarrassment in practice, might terminate in the speedy relief of the patient, and increased credit of the physician.

It must not be supposed, however, that the difficulty terminates, even when the disease is found to be connected with spinal irritation; for experience has demonstrated, that this is in itself not unfrequently a secondary effect;—produced by the disordered functions of other organs. The first object of the medical attendant, therefore, should be to determine whether the affection is idiopathic or sympathetic, acute or chronic.

When the disorder is idiopathic, our attention must be directed to the restoration of the general health of the patient; and an antiphlogistic or tonic line of treatment must be determined on, according to the circumstances of the case. Accordingly the application of leeches, or cupping over the spine where there is tenderness, or stimulants and counter-irritants, should be employed;—according to the general strength of the patient, and the acute or chronic nature of the disease. In

many cases, the loss of blood by leeches has been sufficient to remove the symptoms; in others counter-irritation, as by blistering or the tartar emetic ointment, has succeeded. The tartar is particularly recommended by Mr. Tate; and may be used with every hope of benefit. But when the affection is sympathetic (as is generally the case), in addition to the above means the origin of the malady is to be anxiously sought after; and remedies calculated to remove it are to be administered. By far the most common cause in females, is derangement in the menstrual discharge; and, in such circumstances, the endeavours of the medical attendant should be directed to promote the due performance of this function. If there be irritation in, or improper action of, the digestive or biliary organs, the disordered state should be combated by appropriate remedies. Every medicine employed should have reference to the state of the system, and constitutional powers of the individual; and a low or a nourishing diet prescribed accordingly. In persons of an irritable temperament, change of air, exercise, congenial society, and all methods of distraction, should be recommended. In chronic cases, the disease is often very intractable; but if it have been previously treated in an injudicious manner, much may be effected by the above means. If there be much pain or watchfulness, anodynes are useful; hyoscyamus and belladonna should be preferred;—opium often increasing the irritability. In other respects the treatment should be conducted on the principles laid down under Hysteria and Neuralgia; with which disorders spinal irritation is almost inseparably connected.\*]

## SECTION II.—INFLAMMATION WITHIN THE SPINE.

[This, like *encephalitis*, may be distinguished into:—1. Inflammation of the *membranes*, or spinal *meningitis*. 2. Inflammation of the *substance*, or spinal *myelitis*. The latter may be again distinguished into:—1. Inflammation of the cerebral, or sentient and voluntary tracts. 2. Inflammation of the true medulla. 3. Inflammation of the principal divisions of the medulla.

*Causes.*—The causes of inflammation within the spine are (principally) blows or falls, violent muscular efforts, and exposure to damp or cold. One patient became affected with acute spinal myelitis, from being long exposed to the rain and cold in an open boat. This affection has frequently occurred from the pernicious custom of lying upon damp grass. Rheumatism seems occasionally to have led to this disease. The observations of M. Louis have distinctly shown the connection between caries of the vertebræ and spinal myelitis.

*Symptoms.*—It is rare that meningitis of the spine exists without meningitis within the cranium. It is equally rare for the membranes to be inflamed, or one of the cerebral tracts, without affection of the substance, or of the other portions of the spinal marrow. The distinctions between these affections, therefore, are not easily defined. Happily they are not essential to the treatment. Those symptoms which point to such distinctions will be noticed, however, as we proceed. A much more interesting distinction arises from the various locality of the inflammation;—according as it affects the “medulla oblongata,” or the cervical, dorsal, lumbar, and sacral portions of the spinal marrow. A knowledge of the anatomy and physiology of the part, frequently enables us to define the region of the spinal marrow which is the seat of the disease; and guides us at once in our prognosis, and in the local application of remedies;—the most important part of the treatment.

*Symptoms of Spinal Meningitis.*—In general, the symptoms of meningitis are more those of *irritation* of the spinal marrow, or *spasm*; those of *myelitis*, more those of *destruction* of the organ, or *paralysis*. Both kinds of symptoms may exist, however, or follow each other, in both diseases. Diseases, especially those of the nervous system, are usually more complicated in individual patients, than as they are described in books. Hence a difficulty in the commencement of prac-

\* “Library of Medicine,” Volume 2; Pages 184 to 189.

tice. We are led to expect impossibilities;—diseases well defined in their simple forms. It will be well for us, in reference to our present subject especially, to become well acquainted with the anatomy and physiology of the parts; and we shall then be able justly to interpret each symptom as it appears.

Among the first symptoms of spinal *meningitis*, is local *pain* in some part of the spinal column; augmented by the movements of the patient, and by percussion; but rarely, if ever, by pressure along the spine. This pain sometimes extends along the back and limbs, in which there is then tenderness of pressure;—a symptom which may serve to distinguish meningitis from myelitis, in which there is usually loss of sensibility.

The next important symptom is spasm, or various kinds of muscular contraction. The head, the neck, or the trunk is bent backwards; or there is trismus,<sup>a</sup> torticollis,<sup>b</sup> partial or complete opisthotonos,<sup>c</sup> or contraction of the limbs;—constant, or recurrent, or exacerbated, in paroxysms, on moving, on being moved, &c.; with extreme pain. Sometimes there are convulsions. The respiration is sometimes difficult. There is sometimes retention of urine and constipation.

The symptoms will vary according as the meningitis exists principally at the base of the brain; or at the upper, or the lower, part of the spine.

*Symptoms of Spinal Myelitis.*—The symptoms of spinal *myelitis*, are those of paralysis of sensation and voluntary motion. A sense of numbness (impaired sensibility), and a sense of feebleness (impaired muscular power), are first observed, singly or combined, in one or both of the inferior or superior extremities. In some cases, probably of complication with meningitis, there is augmented sensibility. In other cases there are spasmodic or convulsive affections. If the disease proceeds, the paralysis of sensation and voluntary motion gradually augments. Generally the paralysis affects first the inferior, and afterwards the superior extremities; far more rarely it pursues a contrary course: occasionally the motions alone, and very rarely the sensations alone, are paralyzed. If the disease occupy the *upper* parts of the spinal marrow, the respiration, and even the action of the larynx and pharynx, become impaired; and we have difficulty or choking in swallowing, or asphyxia. There is sometimes the sensation of a cord-like tightness across the epigastrium. If the *lower* part of the spine be affected, the bladder, the rectum, and their sphincters, are variously paralyzed; and there may be retention of urine and constipation, or involuntary evacuations; or retention and involuntary flow of urine may be combined. The condition of the bladder and the condition of the rectum should be ascertained, by proper examinations, *in every case*. In some instances there is perfect impotence, or inertia of the uterus: in others the patient has become a father, or the uterus has been excited to expel the fœtus. These differences, doubtless, admit of explanation by a reference to the *kind* of affection, —irritation, or destruction, and its *locality*,—in the cervical, dorsal, or lumbar portions of the spinal marrow.

*Morbid Appearances.*—The morbid anatomy is, in every respect, similar to that of cerebral meningitis and myelitis.<sup>d</sup> It is rare, indeed, that spinal meningitis occurs without a similar affection of the membranes of the brain. We have injection of the “pia mater,” and of the spinal vessels in general; effusion of serum, lymph, pus, and blood, under the arachnoid, diffused or in portions, and perhaps softening of the adjacent medulla. The arachnoid itself is free from blood-vessels; the morbid changes supposed to take place in this membrane, have their seat in the subjacent cellular membrane, or in the “pia mater.” In *chronic* meningitis, there are sometimes membranous adhesions and effusion, of a cartilaginous hardness.

The principal morbid change in myelitis, is softening; which may occupy the whole, or any portion, either side, or the anterior or posterior part of the spinal

<sup>a</sup> From τριζω, to gnash.

<sup>b</sup> From “torqueo,” to twist; and “collum,” the neck.

<sup>c</sup> From οπισθεν, backward; and τεινω, to draw.

<sup>d</sup> See Page 486.

marrow; it most frequently affects the cervical or lumbar portions. There is, as in the same affection of the brain, a degree of tumefaction. Induration is the frequent result of *chronic* myelitis.

*Treatment.*—The most efficacious treatment of inflammation within the spine, consists (I believe) in the application of cupping in *acute* cases, and of issues and setons in the *chronic*. Cupping may be applied so as to involve the two principles of local depletion and counter-irritation. For this purpose, the scarification should be deep, and crossed; and little blood should be drawn;—the operation being repeated, according to the violence of the disease and the powers of the patient. In reference to the use of issues, M. Louis makes a very apposite remark:—"Experience has demonstrated the utility of issues in Pott's disease; when that affection is of long standing, and voluntary movement more or less injured. A necessary consequence of the foregoing is, that the same means ought to be employed in the simple or primitive softening of the spinal marrow." The administration of mercury in the acute cases, and in the chronic cases when these are uncomplicated with a tuberculous diathesis, is an important measure.

The most moderate diet should be enjoined; the bowels should be kept free; and the recumbent posture, with the utmost quiet, should be preserved.

### SECTION III.—SPINAL APOPLEXY.

Little, I believe, can be said of this form of spinal disease. If it can ever be suspected during life, it can only be from the suddenness of the accession or attack of the symptoms; and the treatment must be the same as in acute inflammation within the spine.

In a very interesting case, (for which I am indebted to Mr. Kiernan,) the "*medulla oblongata*" being *suddenly* compressed, the respiration ceased, and the patient expired instantly. An organic change, which would have produced irritation rather than pressure, would have induced a very different effect.<sup>a</sup>]

### SECTION IV.—SPINA BIFIDA.

*Definition.*—There is sometimes a collection of water low down in the spine; and a tumour is formed externally. From the bone being generally deficient and the spine gaping, the disease is called "*spina bifida*." This, like the accumulation within the head, is sometimes congenital,—born with the child; and sometimes it is not. Sometimes a collection of water will exist with a sound spine; and sometimes the spine is bifid.

*Appearances of the Parts.*—A tumour is produced,—sometimes more than one; and generally the tumour is situated at the lower part of the spine;—in the loins. The higher the tumour is situated, the more rare is the case. These tumours are of all sizes;—from merely a little elevation of the skin, to the size of a child's head. Sometimes the tumour is diffused; sometimes it is very prominent; and sometimes it is both diffused and prominent. It is also of all shades. The skin externally is seen in all conditions. Sometimes it is healthy; sometimes it is very thick; sometimes it is inflamed; sometimes it is gangrenous, ulcerated, and fistulous; and sometimes I have seen it very hairy. The subjacent membranes are likewise found in all sorts of states. Sometimes the membranes are diseased, while the skin remains healthy.

*Characters and Seat of the Fluid.*—The fluid which is contained in these tumours, is exactly like the fluid of hydrocephalus;—for the most part, exceedingly limpid, like rock-water; and its quantity varies, from a few ounces, to six or seven

<sup>a</sup> "Diseases and Derangements of the Nervous System. By Marshall Hall, M. D." Chapter 7; Pages 315 to 319.

pounds. It will exist sometimes in the arachnoid, sometimes between the arachnoid and "dura mater," and sometimes between the arachnoid and the "pia mater;"—that is to say, it will exist in the arachnoid on either side; and it will be found between the "dura mater" and the bones. It has even been found in the canal which runs along the "medulla spinalis."

When there is a deficiency of bone, there is sometimes a fissure all the way through;—from the cervical vertebræ, down to the os coccygis. That, however, is very rare. Sometimes it runs from the last cervical vertebra, down to the beginning of the sacrum; or it exists only in the loins. The latter is a common occurrence. The deficiency is sometimes a mere slit; sometimes there is an imperfect evolution of the lateral arches of the bones; and sometimes there is even separation of the body of the vertebræ also.

*Varieties in the Position of the Cord.*—Besides this variety as to the state of the integuments, as to the state of the membranes, as to the situation of the water, and as to the condition of the bones, there is a great variety also as to the situation of the spinal marrow. Sometimes it is precisely in its natural place; sometimes it runs outside the tumour; sometimes it is distributed upon the sac; and sometimes it has been seen deficient in the affected part.

*Frequent Coexistence of Club-Foot.*—It has been noticed by some, that club-foot frequently coexists with this affection. It is well known, that when there is a species of monstrosity in one part of the body, it is very common to find a defect in another: if an important part (such as the heart or brain) be deficient, it is very common for other parts to be malformed. In this disease, then, club-feet often coexist; but very frequently they do not; because they are only minor deviations from the natural structure of the body. I recollect an instance of a child having this disease, where the tumour was situated on the loins, and was surrounded by a considerable quantity of hair; and there were club-feet; but the tumour ceased spontaneously. No measures were resorted to, for the best part of a twelvemonth; although, when the child was first born, there was the appearance of ulceration, and even gangrene. The disease, however, entirely disappeared; the surface became flat; hydrocephalus commenced; and ultimately destroyed the child.

*Treatment.*—With regard to the treatment of spina bifida, I need not make any remarks. Medicine is of no avail; but cases have been much relieved, if not cured, by puncturing, and by the careful application of a bandage;—exactly the same treatment that has succeeded in hydrocephalus.<sup>a</sup> The part is frequently in a state of gangrene, and then no treatment can be borne; but when the employment of remedial measures is admissible, they are entirely mechanical, and therefore devolve on the surgeon.

---

## CHAPTER VIII.

### CONVULSIONS.

*Definition.*—[By the term "*convulsion*," is meant a diseased state of the muscular tissues; characterized by violent involuntary contractions, with alternate relaxations. This diseased action is common to the muscles both of voluntary and involuntary motion; but occurs much more frequently in the former. The term "*spasm*" has been applied, by some, to the inordinate action of the *involuntary* muscles;—the term "*convulsion*" being more particularly reserved to designate the irregular contraction of the *voluntary* muscles. When the contractions have been

<sup>a</sup> See Page 511.

of some duration, and are not quickly succeeded by alternate relaxations, they have been called "*tonic* convulsions;"—exemplified in tetanus; whilst involuntary alternate motions of contraction and relaxation have been termed "*clonic* convulsion;" of which hysteria affords an example. The term "*convulsion*" has sometimes been exclusively appropriated to *clonic* convulsion; but as the principal difference between *clonic* and *tonic* convulsions consists in degree, and they both originate in the same causes, it is more convenient for practical purposes to include them under the same head. Very slight and quick alternations of contraction and relaxation, constitute what is called "tremor."<sup>a</sup>

Convulsions manifest themselves in various degrees, and under various forms. They occur as a symptom in the course of many diseases; and they sometimes assume such regular and well-defined characters, as to constitute distinct and separate diseases; as, for instance, in the case of tetanus and hysteria. There are, however, attacks of simple convulsion, partial and general, that cannot be referred to hysteria, epilepsy, or any of the well-defined convulsive affections which have received generic names.<sup>b]</sup>

*In Infants.*—Children are very liable to epileptic fits and regular convulsions; from irritation of the bowels, teething, and other circumstances. These will sometimes depend upon the mere circumstance of teething; and cease if the gums be lanced. Sometimes they arise from the intestines, and are cured by purging; so that other antiphlogistic measures are not required; but sometimes they depend on, and are connected with an inflammatory state of the head; and after death we find the same appearance as in hydrocephalus;<sup>c</sup>—at least, the lining membrane of the ventricles is as red as a piece of scarlet cloth.

*Treatment.*—The treatment of convulsions (if we cannot discover in the gums or intestines an exciting cause, which it is in our power to remove) should be, if the pulse will justify it, the same as for hydrocephalus.<sup>d</sup> We must take blood away freely, give mercury, and put ice on the head. But it is necessary here to make the same diagnosis that we do in hydrocephalus.<sup>e</sup> These convulsions may be connected with debility, with a weak pulse, with paleness of the face, or with only a transient flushing of it; and, in such cases as these, assafoetida, or a small quantity of laudanum, or ammonia, may answer a good purpose.<sup>f</sup> In these cases of convulsions, cold affusion has frequently been attended with very good effect. In the work of Dr. Currie on Cold Affusion,<sup>g</sup>—a sort of classical work in medicine, and well worth reading,—he mentions several cases of convulsions in children, where they ceased immediately on the sudden application of cold water. Now if these convulsions had arisen from an inflammatory state, the effect would not have been of this kind. We cannot cure inflammation by merely throwing cold water on a patient. It is clear that the convulsions of children may frequently arise from irritation, not within the head, but connected with a distant part; but if there be an over-fulness of the head in particular, or of the system at large, without marks of inflammation, or still more *with* marks of inflammation, it is not right to trust to any thing but the common antiphlogistic remedies vigorously applied.

*Chronic Convulsions.*—The *chronic* convulsions of children are allied to epilepsy; and must be treated in the same way.

<sup>a</sup> "Spasm" is morbidly *increased* action; "paralysis" is morbidly *diminished* action; "convulsion" is *irregular* action. "Tremor" is a loss of balance from *diminished* action,—approaching to *palsy*; "convulsion" is a loss of balance from *increased* action,—approaching to *spasm*. A "*clonic* spasm" is a convulsion. Palpitation of the heart is an example.—*Dr. Fletcher.*

## CHAPTER IX.

## EPILEPSY.\*

*Synonymes.*—The disease next to be spoken of is epilepsy. The name of the disease is given to it from the suddenness of the seizure;—from *επιλαμβάνω*, *to seize upon*. It is also called, in Latin, “*morbus comitialis*,” because if a person in the “comitia,” or popular assemblies, of the Romans was seized with the disease, it was considered a bad omen, and the comitia were dissolved. It is also called “*morbus spūla*,”—“the *spitting* disease;” from the custom of spitting into the bosom, to avert the unfavourable omen. The Romans were remarkably superstitious; and fancied it was a sign of ill luck to be seized with a fit; and therefore they spit into their bosoms, to save themselves from something pernicious, or to do good to the patient. In common language it is called “the *falling* sickness;” and, now that the lower orders have got hold of fine names, they call it by various appellations. The Jews ascribed it to the influence of demons; it is also indicated in the New Testament; where persons are said to have been suddenly seized by an evil spirit, and to have fallen into the water or fire;<sup>a</sup> because a patient who is liable to the disease may be near fire or water, and he will fall into the one or the other.

## SECTION I.—PROGRESS AND VARIETIES.

*Definition.*—In epilepsy, there is a sudden loss of sense, with convulsions of the voluntary muscles; and the loss of sense continues after the convulsions have ceased;—so that a person is said to “go to sleep” after the fit.

*Symptoms of the Attack.*—In the fit, the countenance is ghastly and pale, or perhaps of a bluish red; it is sometimes sallow. The lips are livid; the neck and the cheeks are much swollen; and, perhaps, the whole body is bedewed with sweat; but especially the head and cheeks. There is foaming at the mouth; and generally the tongue is bitten. There are universal violent convulsions, horrid grimaces, a rolling of the eyes, and dilatation of the pupils. Sometimes it happens that the urine and fæces are discharged involuntarily;—the urine most frequently; and occasionally there is a discharge even of semen, with or without an erection;—I do not know which. The hands are generally clenched, in the fit; and the heart palpitates strongly. The pulse is quick; and the respiration is short, deep, and irregular.

*Not attended by suffering.*—When the patient wakes from the state of sopor, he has generally no recollection of what has passed; and perhaps, therefore, there is no suffering. The want of *recollection* of suffering, however, is no proof that there has been *no* suffering; for we have all suffered enough in cutting our teeth, and yet we know nothing of it now. So it may happen respecting more recent events. The fit *may* be attended with more or less suffering; but I should think there was none, for persons do not suffer, in general, when they are hung;—although they may struggle, and hang so long as to be insensible, and almost dead. There is an account, in Lord Bacon’s works, of a person who was hung, and all but killed; and yet he did not suffer. From a short account written by Cowper,

<sup>a</sup> “There came to Him a certain man, kneeling down to Him, and saying—‘Lord, have mercy on my son; for he is lunatic and sore vexed! For oftentimes he falleth into the fire, and oft into the water.’ And Jesus rebuked the devil; and he departed out of him; and the child was cured from that very hour.”—“*The Gospel according to Matthew*,” Chapter 17; Verse 15.

the poet, it appears that he three times attempted to commit suicide; and one of these attempts was by suspension. The account was written by himself; and was found among his manuscripts. It is very scarce;—on account of its having been bought up. He there mentions, that he suspended himself over his chamber-door, in the Temple; and became perfectly insensible. He only recollected a flash of light appearing before his eyes. His weight at last caused him to drop on the floor, where he was found; and, after a time, he recovered.\* He says that,

\* One evening in November, 1763, as soon as it was dark,—affecting as cheerful and unconcerned an air as possible,—I [Cowper] went into an apothecary's shop, and asked for a half-ounce phial of laudanum. The man seemed to observe me narrowly; but if he did, I managed my voice and countenance, so as to deceive him. The day that required my attendance at the bar of the House [of Commons] being not yet come, and about a week distant, I kept my bottle close in my side-pocket;—resolved to use it when I should be convinced there was no other way of escaping.—Not knowing where to poison myself,—for I was liable to continual interruption in my chambers [in the Temple] from my laundress and her husband,—I laid aside that intention, and resolved upon drowning. For that purpose, I immediately took a coach; and ordered the man to drive to Tower-Wharf;—intending to throw myself into the river from the Custom-House-Quay. I left the coach upon the Tower-Wharf;—intending never to return to it: but, upon coming to the quay, I found the water low, and a porter seated upon some goods there;—as if on purpose to prevent me. This passage to the bottomless pit being mercifully shut against me, I returned to the coach, and ordered it to the Temple. I drew up the shutters [off the coach], and once more had recourse to the laudanum, and determined to drink it off directly; but God had otherwise ordained. A conflict, that shook me to pieces, suddenly took place; not properly a trembling; but a convulsive agitation, which deprived me (in a manner) of the use of my limbs; and my mind was as much shaken as my body. Distracted between the desire of death, and the dread of it, twenty times I had the phial to my mouth, and as often received an irresistible check; and, even at the time, it seemed to me that an invisible hand swayed the bottle downwards, as often as I set it against my lips. I well remember, that I took notice of this circumstance with some surprise;—though it effected no change in my purpose. Panting for breath, and in horrible agony, I flung myself back into the corner of the coach. A few drops of laudanum which had touched my lips, besides the fumes of it, began to have a stupefying effect upon me. Regretting the loss of so fair an opportunity, yet utterly unable to avail myself of it, I determined not to live; and, already half-dead with anguish, I once more returned to the Temple. Instantly I repaired to my rooms; and, having shut both the outer and inner door, prepared myself for the last scene of the tragedy. I poured the laudanum into a small basin, set it on a chair by the bed-side, half undressed myself, and laid down between the blankets;—shuddering with horror at what I was about to perpetrate. I reproached myself bitterly with folly and rank cowardice, for having suffered the fear of death to influence me, as it had done; and was filled with disdain at my own pitiful timidity: but still something seemed to overrule me, and to say,—“Think what you are doing! Consider, and live!” At length, however, with the most confirmed resolution, I reached forth my hand towards the basin; when the fingers of both hands were as closely contracted as if bound with a cord, and became entirely useless. Still, indeed, I could have made shift with both hands,—dead and lifeless as they were,—to raise the basin to my mouth; for my arms were not at all affected: but this new difficulty struck me with wonder;—it had the air of a divine interposition. I lay down in bed again, to muse upon it; and, while thus employed, heard the key turn in the outer door, and my laundress's husband came in [to the outer room]. By this time, the use of my fingers was restored to me. I started up hastily; dressed myself; hid the basin; and, affecting as composed an air as I could, walked out into the dining-room. In a few minutes I was left alone; and now, unless God had evidently interposed for my preservation, I should certainly have done execution upon myself;—having a whole afternoon before me. Both the man and his wife having gone out, outward obstructions were no sooner removed, than new ones arose within. The man had just shut the door behind him, when the convincing spirit came upon me, and a total alteration in my sentiments took place. The horror of the crime was immediately exhibited to me in so strong a light, that—being seized with a kind of furious indignation—I snatched up the basin, poured away the laudanum into a vessel of foul water, and—not content with that—flung the phial out of the window. This impulse, having served the present purpose, was withdrawn. I spent the rest of the day in a kind of stupid insensibility;—undetermined as to the manner of dying, but still bent on self-murder, as the only possible deliverance.

I went to bed, to take (as I thought) my last sleep in this world. The next morning was to place me at the bar of the House; and I determined not to see it. I slept as usual, and awoke about three o'clock. Immediately I arose, and (by the help of a rush-light) found my penknife, took it into bed with me, and lay with it (for some hours) directly pointed against my heart. Twice or thrice I placed it upright under my left breast;—leaning all my weight upon it; but the point was broken off square, and it would not penetrate. In this manner the time passed, till the day began to break. I heard the clock strike seven;

although he was thus in the jaws of death, and had become perfectly insensible, yet he had no previous suffering; and therefore, as there was no suffering in that state, it is probable that there is no suffering in epilepsy;—that there is such a state of insensibility that nothing is experienced. I should suppose that in drowning there is no suffering, if it occur at once. Shakspeare's expression is—

“ Oh Lord! methought what pain it was to drown!”<sup>a</sup>

but there is no reason to suppose there is pain, if the individual go down and do not come up again; but if he come out of the water, the suffering is dreadful.

*Duration of the Attack.*—The convulsions of epilepsy may last from a moment, to fifteen minutes or more; and sometimes they recur after they have ceased, before the sopor is over. The sopor, or coma, is generally complete, both during the convulsions, and for some time subsequently; but not always. This, therefore, is the character of epilepsy;—a sudden attack of convulsions of the voluntary muscles, together with insensibility;—the insensibility continuing after the convulsions have ceased.<sup>b</sup>

*Most frequently attacks One Side.*—Frequently, like all diseases of the nervous system, it occurs more on one side than on the other. Paralysis frequently

and instantly it occurred to me, that there was no time to be lost: the chambers would soon be opened; and my friend would call upon me, to take me with him to Westminster. “ Now is the time!”—thought I. “ This is the crisis! No more dallying with the love of life!” I arose; and, as I thought, bolted the inner door of my chambers; but was mistaken: my touch deceived me, and I left it as I found it. My preservation, indeed, as it will appear, did not depend upon that incident; but I mention it, to show that the good providence of God watched over me, to keep open every way of deliverance;—that nothing might be left to hazard.

Not one hesitating thought now remained: I fell greedily to the execution of my purpose. My garter was made of a broad piece of scarlet binding, with a sliding buckle;—being sewn together at the ends. By the help of the buckle, I formed a noose, and fixed it about my neck; straining it so tight, that I hardly left a passage for my breath or for the blood to circulate: the tongue of the buckle held it fast. At each corner of the bed, was placed a wreath of carved work, fastened by an iron pin, which passed up through the midst of it; the other part of the garter, which made a loop, I slipped over one of these; and hung by it some seconds;—drawing up my feet under me, that they might not touch the floor. But the iron bent; and the carved work slipped off, and the garter with it. I then fastened it to the frame of the tester;—winding it round, and tying it in a strong knot. The frame broke short, and let me down again. The third effort was more likely to succeed. I set open the door, which reached within a foot of the ceiling. By the help of a chair, I could command the top of it; and the loop, being large enough to admit a large angle of the door, was easily fixed so as not to slip off again. I pushed away the chair with my feet, and hung at my whole length. While I hung there, I distinctly heard a voice say, three times,—“ ’Tis over!” Though I am sure of the fact, and was so at the time, yet it did not at all alarm me, or affect my resolution.

I hung so long that I lost all sense,—all consciousness of existence. When I came to myself again, I thought myself in hell. The sound of my own dreadful groans was all that I heard; and a feeling like that produced by a flash of lightning just beginning to seize upon me, passed over my whole body. In a few seconds, I found myself fallen on my face to the floor. In about half a minute, I recovered my feet; and, reeling and staggering, stumbled into bed again. By the blessed providence of God, the garter which had held me till the bitterness of temporal death was passed, broke just before eternal death had taken place upon me. The stagnation of the blood under one eye (in a broad crimson spot), and a red circle round my neck, showed plainly that I had been on the brink of eternity. Soon after I got into bed, I was surprised to hear a noise in the dining-room; where the landress was lighting a fire. She had found the door unbolted, notwithstanding my design to fasten it; and must have passed the bed-chamber door, while I was hanging on it; and yet never perceived me. She heard me fall, and presently came to ask me if I was well;—adding, that she feared I had been in a fit. I sent her to a friend, to whom I related the whole affair; and despatched him to my kinsman, at the coffee-house. As soon as the latter arrived, I pointed to the broken garter, which lay in the middle of the room; and apprised him, also, of the attempt I had been making. His words were:—“ My dear Mr. Cowper, you terrify me! To be sure you cannot hold the office at this rate. Where is the deputation?” I gave him the key of the drawer where it was deposited; and, his business requiring his immediate attendance, he took it away with him; and thus ended all my connection with the parliamentary office.—*Cowper's Works; edited by Dr. Southey; Volume I; Chapter 5; Pages 122 to 131.*

<sup>a</sup> “ Richard the Third,” Act I; Scene 4.

<sup>b</sup> See Page 593.

does so; St. Vitus's dance affects one side more than the other; hysteria does the same; and we find that epilepsy likewise has the same tendency.

*Occurs most frequently during Sleep.*—The fits of the disease most frequently occur during sleep, or in the state intermediate between sleeping and waking; when we all experience a little delirium. If we fall asleep in a *moment* from a waking state, there is no delirium; but if we *fall* asleep *gradually*, the mind wanders. If we wake *suddenly* there is nothing of the kind; but if we wake very *slowly*, then again a little delirium is experienced. We are more accustomed, however, to *go to sleep* gradually, than to *wake* so; and therefore the delirium is observed far more commonly in going to sleep, than in waking. Now it is at the instant when a person is neither in full action nor at complete rest, that epilepsy particularly attacks him. A great number of persons have a fit, just when they are going to sleep, or when they awake;—many have it when they are asleep; and, again, some only have it either when they are going to sleep, or when they are about to awake.

*Warning of its Occurrence.*—Occasionally the patient has no warning whatever; and has no knowledge of the fit. I have seen many persons who are not at all aware that they have fits. These have been persons in the decline of life, who are in the habit of sitting in the house;—not going about so as to run the chance of being injured; and who have been watched by the rest of the family. I have known them have fits for years; and yet they have not been aware of it;—at least they *pretended* they were not. The individual has been seized in a moment; and has afterwards wondered what has been the matter. But some persons have good warning. Some, previously to the attack, have vertigo and headache, sufficient to show that they are going to have it. Sometimes there is just vertigo enough, and no more, to enable them to escape from danger. Some have headache, a day or two before the vertigo; but some have vertigo only just in sufficient time to make them get out of the dangerous situation in which they are placed. Occasionally, a spectre has been seen at the moment of the fit;—an image has passed before the mind, before the fit took place. I recollect that Dr. Gregory<sup>a</sup> used to mention, in his lectures, that he knew a patient who, before the fit, saw a little old woman come out of the corner with a stick; and when she approached and struck him, down he fell in a paroxysm. It is a mental delusion of the moment, produced by an excitement of the brain. The fact is mentioned by Sir Walter Scott, in his “Letters on Demonology and Witchcraft;”—certainly not one of his best books.”<sup>b</sup>

<sup>a</sup> See Note to Page 239.

<sup>b</sup> A patient of Dr. Gregory, a person (it is understood) of some rank, having requested the doctor's advice, made the following extraordinary statement of his complaint:—“I am in the habit of dining at five; and, exactly as the hour of six arrives, I am subject to the following painful visitation. The door of the room, even when I have been weak enough to bolt it (which I have sometimes done), flies wide open; an old hag, like one of those who haunted the heath of Forres [alluding to the witches in “Macbeth”], enters with a frowning and incensed countenance, comes up to me with every demonstration of spite and indignation which could characterize her who haunted the merchant Abudah in the Oriental tale; she rushes upon me, says something, but so hastily that I cannot discover the purport; and then strikes me a severe blow with her staff. I fall from my chair in a swoon; which is of longer or shorter endurance. To the recurrence of this apparition I am daily subjected;—such is my new and singular complaint.” The doctor immediately asked, whether his patient had invited any one to sit with him, when he expected such a visitation. He was answered in the negative. The nature of the complaint, he said, was so singular, it was so likely to be imputed to fancy, or even to mental derangement, that he had shrunk from communicating the circumstance to any one. “Then,” said the doctor, “I will dine with you to-day, tête-à-tête; and we will see if your malignant old woman will venture to join our company.” The patient accepted the proposal, with hope and gratitude; for he had expected ridicule rather than sympathy. They met at dinner; and Dr. Gregory, who suspected some nervous disorder, exerted his powers of conversation, (well known to be of the most varied and most brilliant character,) to keep the attention of his host engaged, and prevent him from thinking on the approach of the fatal hour, to which he was accustomed to look forward with so much terror. He succeeded in his purpose better than he had expected. The hour of six came almost unnoticed; and, it was hoped, might pass away without any evil consequence; but it was scarce a moment struck, when the owner of the house exclaim-

Sometimes, before the fit, the patient utters a loud scream. He is not aware of any suffering that occasions him to do it; but only says that he cannot help screaming. Sometimes the patient has a warning during the *first* fits; but when he has been long subject to the disease, *no* warning takes place. Sometimes, after a fit, not only will a patient forget it, but no symptom remains; on the other hand, people will occasionally be subject, for some days, to headache and sleepiness. Sometimes these symptoms only remain a few hours; but in other cases they will remain a few days.

*Aura Epileptica.*—Sometimes, before the fit, there is a warning; occasioned by a sensation of tickling, or crawling, along the surface of the body. There is a sensation as if fluid were creeping from the fingers, or from the thighs, towards the trunk; and sometimes as though a spider or flea were creeping over the skin. When it appears like fluid, it is generally like *cold* fluid. This has been ascribed to a sort of rush of air or wind, and has been called "aura;" and, being connected with the epilepsy, it is called "*aura epileptica*." It does not follow the course of particular nerves. It appears to reside in the skin; and there is certainly no connection between it and the neurilemma of the part. I have seen several instances of this affection; and I made a note of one case, in 1826. A boy had a sensation of two auræ; which ran along the dorsum of the foot, up the front of the legs and thighs. Each stream ran up the trunk, and they met at the epigastrium; and then it seemed as if there were five streams, running from the two up the trunk. As soon as the auræ got to the epigastrium, down he fell. He compared the sensation, which was very rapid, to that of the creeping of a spider. I had another case of the same kind, in May, 1826.

*Frequency of the Fits.*—Occasionally, the fits are very numerous at first; but gradually become less so. While, however, they become less numerous, they generally become more severe, and last longer. I think, in the majority of cases, the fits are most frequent at first; so that a person will have a dozen or twenty in a day; but as they become fewer, I have generally observed them last longer, and the severity is greater. Occasionally I know the reverse takes place;—they are not so numerous at first. Some have but one fit for many years;—an interval of many years occurring before another takes place; and, so far as I know, some have but one fit during life. It has proceeded from some temporary cause; and the disease has never recurred.

*The Mind becomes Impaired.*—If the disease have continued long, and the fits have not been very infrequent, the mind generally becomes impaired; but if the disease have continued long, and yet the fits have not recurred except at long intervals, then the mind is not impaired. The reason is simply this;—the disease of the brain, which gives rise to these fits, at last disturbs other functions. It is not the *epilepsy* that causes it; but the *cause* of the epilepsy impresses other parts of the brain. That the disease, however, does not necessarily impair the mind, is shown by the example of Julius Cæsar, and Napoleon; both of whom, we are told, were subject to it.<sup>a</sup>

*Complicated with other Diseases.*—It is very common for one, two, or more

ed, in an alarmed voice,—“The hag comes again!”—and dropped back in his chair in a swoon;—in the way he had himself described. The physician caused him to be let blood; and satisfied himself that the periodical shocks of which his patient complained, arose from a tendency to apoplexy.—“*Letters on Demonology and Witchcraft*. By Sir Walter Scott.” Letter 1; Pages 23 to 25.

<sup>a</sup> *Cassius*. Did Cæsar swoon?

*Cæsar*. He fell down in the market-place, and foamed at the mouth, and was speechless.

*Brutus*. 'Tis very like! He hath the “falling sickness.”

“*Julius Cæsar*,” Act 1; Scene 2.

It is reported that afterwards, he [Cæsar] imputed it [his conduct to the Senate] to his disease;—saying that their wits are not perfect which have this disease of the “falling evil;” when, standing on their feet, they speak to the common people; but are soon troubled with a trembling of their body, and a sudden dimness and giddiness.—“*Pictorial Edition of Shakspeare*,” Part 35 (“*Julius Cæsar*”); *Tragedies*, Volume 2; Page 236. (Quoted from North’s Translation of “*Plutarch’s Lives*.”)

diseases of the nervous system to be united; and we find, in illustration of this observation, that epilepsy frequently occurs in chorea, in hysteria, in insanity, in idiotism,<sup>a</sup> and not unfrequently in palsy;—that is to say, the pathological state of the brain or spinal marrow, or both, will produce sometimes one symptom, and sometimes another. The disease may be such, as to extend from one portion to another, and to affect various parts. This union of different diseases of the nervous system, is almost always seen. In St. Vitus's dance, there is a peculiar constitution of the mind,—a little fatuity. Apoplexy and palsy we see united every day; and apoplexy is the common termination of many diseases of the nervous system;—of insanity, for example. These different nervous diseases may coexist or succeed each other.

*Variety of Epilepsy.*—There is a great variety in epilepsy. That which I have just described is the most common form; but there are very great varieties;—so that persons may quarrel about the definition, if they choose; and say that such and such forms are not epilepsy. If we define epilepsy to be “a *complete* loss of sense, with *general* convulsions,” then an *incomplete* loss of sense, or *partial* convulsions, is not to be considered epilepsy. But it is not wise to quarrel about terms, in this way, so long as we understand what is meant by them.

It will sometimes happen that there is decided insensibility *before* the convulsions take place; and that *during* the convulsions, the person becomes more or less sensible. This is one form in which the disease appears. Occasionally patients have no convulsions at all;—they will simply fall down in a state of insensibility, and rise up again without knowing what is the matter with them. Occasionally, instead of these convulsions occurring throughout the body, they are confined to one side; and sometimes they are still more partial;—being confined to one extremity. Sometimes, instead of convulsions, there is mere tremor of the body; or a part of the body will shake violently. Occasionally, during the fit, there is delirium. The person shows that he is not insensible; but, instead of being insensible, he is in a state of violent delirium;—apparently in an alarming condition; although in general, I believe there is no danger at all. Sometimes patients have this delirium on recovering from a comatose state. Occasionally the disease assumes the form of partial tetanus; one-half of the body being in a state of the most intense spasmodic rigidity. I have seen two cases, where the person was seized, at the moment of the convulsions, with a spasm of one-half of the body, attended with the most excruciating pain. One arm and one leg have been drawn up; yet there has been no danger; and the nature of the case has been shown very plainly, by the next paroxysm being epileptic.

*Ecstasis.*—Sometimes there is a variety in what occurs in this respect;—a person is insensible to all around him; and yet has, before the fit, no *internal* unconsciousness. I have seen several instances where, before the fit, the patient became unconscious of external objects;—that is to say, the comatose state came on before the convulsions; but, in that apparently comatose state (a state of sopor in which there was no perception of any thing around) the patient was internally in a state of activity; and that condition is called “ecstasis;”<sup>b</sup>—whether it be united with epilepsy or not. In this state, people sometimes walk, dress themselves, and even compose poetry; and yet they have no knowledge of it. If they be awakened in this condition, they are alarmed; or, at least, they are surprised at the situation in which they are placed. Sometimes they recollect it all;—just as we recollect a dream. Sometimes we may remember a dream, but sometimes we have no knowledge of it; while those near us see that we have been dreaming. So it is in this state of ecstasy, which consists in the mind being internally active. Sometimes the paroxysms are not quite complete; so that a person is half aware of what is going on about him. If the patients be in a situation where they have frequently been before, and have become habituated to it, they have been known to walk over

<sup>a</sup> See Page 543.

<sup>b</sup> From ἐκστασις, to be mentally deranged.

difficult places, where there was the greatest danger, with impunity. These places, however, were well known to them; so that habit influenced their motions. Sometimes, however, the activity of the mind is so imperfect, that they know where the window is, and how to open it, yet they forget that there is the street beyond the window; and they step out, and are dashed to pieces. This all arises from an imperfect activity of mind. This state of ecstasis is nothing more than active dreaming. In dreaming we are often active, reason correctly, and even compose poetry; but in this state of ecstasis, more than that is done;—persons will compose to a great extent, reason accurately, and perform voluntary motion,—so as to go from one place to another, and do many things; and yet, for the most part, they will be ignorant of it. A patient of mine had this ecstasis before the paroxysm of epilepsy. She was a girl, and subject to epilepsy; and, before she fell down, she was insensible to all around her; but, in the state of insensibility, she used to hum “Robin Adair,” and “Home, sweet home,” so correctly, that none could find fault with her; but she was quite unconscious of it. After this, the activity of the mind ceased; she became unconscious internally as well as externally; and the convulsions then came on. I had another patient, more religiously and devoutly disposed; and she always sung *hymns*, and in good time.

Dr. Darwin considered this somnambulism, or “walking in the sleep,”<sup>a</sup> (which is only an imperfect degree of sleep,) to be an epileptic disease. Whether it is *true* epilepsy or not, is another thing; but he considered it to belong to the family of epileptic affections. Dr. Prichard, of Bristol, (whose work on nervous diseases<sup>b</sup> is well worth reading,) considers walking in the sleep and ecstasis to be both of an epileptic character. If a person be *asleep*, and be seized with a partial consciousness, and partial voluntary power, it is called “somnambulism;” but if he be seized in a *waking* state, then it is called “ecstasis.” It is the same state; only it may begin when we are *asleep*, by a degree of *activity*; or when we are *awake*, by a degree of *insensibility*. They come exactly to the same thing. They frequently occur without epilepsy; but they are frequently united with it.

*Night-Mare.*—The night-mare is considered by some as allied to epilepsy. In the night-mare, which is technically called “*incubus*,”<sup>c</sup> there is a degree of sense, but a deceptive feeling;—generally some unpleasant dreams, and more or less loss of volition. There is a strong, but ineffectual desire to make a muscular effort. It is only a variety of somnambulism; and when the paroxysm ceases, we can make a voluntary effort: whence it is imagined, we get rid of the night-mare by making the effort; whereas the effort is made because the diseased state ceases. I think it is a slight degree of epileptic affection. There can be no doubt that it is a cerebral affection; and it may arise from eating suppers, and from other causes. It is singular that there is one house in the country, where I always have the night-mare; and in my own case the spectre has taken the shape of a devil, with a colour like that of oil-skin. The house is that of a friend of mine. I repeatedly changed my bed-room: and at last I did not go to bed at all, but slept in the drawing-room. Still, however, I had the night-mare. I do not know the reason. Possibly it was going from London, partaking of a late dinner, eating more than I should, being cheerful from seeing my friends, and then going to bed. Certain it is that in that house, for four or five years, I regularly had the night-mare.

*Coma without Convulsions.*—The state of ecstasis I have described, precedes the commencement of the fit; and I believe it sometimes takes place *after* the fit; but other varieties take place in the fit itself. I mentioned that, sometimes, the coma ceases when the convulsions come on;<sup>d</sup> and some people have coma without convulsions at all;<sup>d</sup> and that is a kind of epilepsy which is frequently mistaken for apoplexy. Many persons are said to have twenty fits of apoplexy, when they have never had one. Old people will fall down senseless; and will get up again, just as if nothing had happened; and if a practitioner be near, he bleeds them; and

<sup>a</sup> From “*somnus*,” *sleep*; and “*ambulo*,” *to walk*.

<sup>b</sup> “*Treatise on Diseases of the Nervous System*; by J. C. Prichard, M. D.”

<sup>c</sup> From “*incubo*,” *to sit upon*.

<sup>d</sup> See Page 598.

a cure of apoplexy is thought to be effected; but there is no reason to suppose that it is any such thing. It appears to be only imperfect epilepsy,—epilepsy without convulsions; for there is no stertorous breathing; no harm arises from it; and such persons very frequently, sooner or later, have regular epilepsy. A slight degree of this is sometimes seen;—so that persons will not lose themselves entirely. They feel that they are going; they catch hold of something; and they are right again. It is, no doubt, an imperfect form of epilepsy. The coma is not fully formed; lasting only a few moments. I have known this occur; and then the coma to last longer, and be more perfect; till, after some years, the coma has been joined with convulsions; so that I have no doubt elderly persons (and sometimes it happens to young ones) fall down senseless, and come to, without suffering any consequences whatever; and have frequent attacks of it. Occasionally, mere faintness is produced;—not enough to make the person take hold of any thing.

*Partial Convulsion.*—The convulsions, I mentioned,<sup>a</sup> are sometimes very local. Sometimes it is only an arm or a leg that is convulsed. I had a case occurring in a boy, in 1828, whose muscles at the back of his head were affected; and likewise the muscles of his eyes. He was frequently seized with a fit; which made him hold up his head, and begin winking his eyes. During this state of partial convulsions, his head was drawn back, and he was perfectly insensible; but he never dropped down. His father once fired a pistol close to his ear; but the boy took not the least notice of it. He would heave a deep sigh, stir about, and be himself again. I have seen him, repeatedly, in a paroxysm of this description. He would have thirty fits in a day; stand still all the time; and be perfectly unconscious of them. There was a boy in St. Thomas's Hospital, who was nearly in the same state. When he was attacked he held his forehead, and said he was unconscious. I never saw *him* in a fit; but I have frequently seen the other boy in one. So imperfect is the fit, that if the patient be eating his dinner at the time, he continues to masticate as though the fit were not on him; but he is quite unaware of what he is doing. I had another patient, in whom the head was drawn down; and, when sitting at a table, down his head would come upon it; till his nose was beat flat, like a kidney. Before he had epilepsy, his mother said, he sat "nod, nodding;" till his nose was almost as flat as the rest of his face. I have seen cases affecting one part of the body only. I had under my care an old lady who had had hemiplegia of one side; and this side became subject to epilepsy, and was convulsed from time to time. It is useful to know these things; because we might think that a patient, in these anomalous forms of epilepsy, was suffering under some structural disease that might prove dangerous. If it be merely epilepsy, we may give a much more favourable prognosis, so far as life and death are concerned; though the prognosis in epilepsy is generally unfavourable, because it is rarely curable.

*More frequent in Youth.*—This is a disease, which is very common in infants and young children; and it will sometimes continue till puberty, and then cease; but it will sometimes occur again, after the sexual period of life is over. I had a patient (an old lady) who informed me that she had epilepsy, when a child, every few weeks; and that the fits gradually grew rarer, till puberty. During the menstruating period they ceased, and she had no fit for thirty years; but when menstruation ceased, then she had a fit every year or two:—sometimes not so often. She had pain in the occiput, for five years, before the disease returned; and, one day, she suddenly fell down dead. Here was an instance, within my own knowledge, of a person having the disease when a child; of its ceasing at puberty, and during the menstruating period; and of its beginning again, when she relapsed into her former state. Generally, when the disease lasts through life, it begins just before puberty, or about that time. Dr. Heberden not only observed this, but also states that there was no mitigation from puberty, so far as he could judge from his experience.<sup>b</sup> It is generally imagined, that puberty mitigates the disease or destroys

<sup>a</sup> See Page 598.

<sup>b</sup> See his "Commentaries;" Chapter 33. (First Edition; Page 163.)

it altogether; but I believe that the hopes of parents, on that point, are usually false; and that puberty does not influence it. Either so many young persons die of the disease, and do not grow old, or it ends in other nervous diseases,—particularly insanity; so that, at last, the individual is put in the class of insane persons. Whatever may be the reason, we certainly see it more frequently in *young*, than in *old* people; and I suppose it arises from a variety of causes. Persons become fatuous; and then the epilepsy is considered only a secondary matter; and now and then it ceases altogether. Old people are most subject to that form of epilepsy, which is characterized by coma without convulsions;<sup>a</sup> and which, I stated,<sup>b</sup> is often mistaken for apoplexy.

*Most frequent in Males.*—Males are more subject to the disease, than females; except when it occurs in young children and infants. In infants, the proportion is just the same; because there is not the individual difference of constitution; but as the period of puberty arrives, and there is the distinction between the sexes, then it is more common among males than females. I once made a calculation of the number of patients I had had with this disease. In 1829, I found that I had had in the hospital thirty-seven patients; twenty-seven of whom were males, and only ten females. They were nearly all boys and girls; so that it is much more commonly seen in *young* persons, than in *old* ones.

## SECTION II.—CAUSES.

*Hereditary Predisposition.*—With regard to the causes of the disease, we may first mention a certain hereditary predisposition. This is shown, perhaps,—not by brothers and sisters, and predecessors (uncles and aunts, fathers and mothers, grandfathers and grandmothers) having had *this* disease,—but by their having had other affections of the nervous system. The same state of the nervous system will frequently not produce the same disease;—one may have epilepsy, and another some other nervous affection. When, however, these things occur in different generations, we may class them together, and consider them as the development of an hereditary predisposition. We continually see, in females, something wrong in the nervous system; but it does not produce the same effect in all. Some will have one disease, and some another.

*The Form of the Head.*—Epilepsy is frequently conjoined with a curious form of the head: it is very often united with a deficiency of brain; and (of course) with fatuity, or idiocy. Epilepsy is frequently united with that form of idiocy which depends, not upon *disease* of the brain, but upon a *deficiency* of brain. Many people have a narrow forehead;—a low forehead, sloping back; and they have epilepsy. This is not universal, nor indeed *general*; for any derangement of the nervous system may produce epilepsy. Many persons are idiots, not from there being a deficiency of brain, but from the brain being of bad quality; but there is one kind which depends entirely upon a deficiency of the anterior part of the brain; that no one now can deny. Where such is the case, it is common for epilepsy to be united with it. It is very common to find a sugar-loaf form of the head in epileptic patients. Epilepsy is sometimes united with a large head. I mentioned that the hydrocephalic man,<sup>c</sup> who had ten pints of water in his head, was epileptic.<sup>d</sup> Sometimes it arises from a preternaturally thick skull; and, on the other hand, epilepsy may accompany the most beautifully formed head; simply from some accidental disease in the head. However, one circumstance connected with the predisposition to epilepsy, is an idiotic form of the head;—a shallowness of brain. Not that I conceive the shape of the head has any thing to do with the production of the disease; but where the brain is more or less deficient in development, very frequently the patient is likewise epileptic.

*Cerebral Disease.*—Epilepsy sometimes exists in chronic hydrocephalus, and

<sup>a</sup> See Page 598.

<sup>b</sup> See Page 599.

<sup>c</sup> Cardinal.

<sup>d</sup> See Pages 509 and 510.

various other diseases of the head; but we frequently see it in the best formed head. There is a predisposition to it, indeed, from any cerebral disease whatever. Whatever disease may exist in the brain, the person so affected is very liable to have epilepsy. The same state which produces one disease of the brain, may (either by its intensity, or by extending to other parts) produce epilepsy. Very often, however, the predisposition to this disease is inexplicable. A person is seized with an epileptic fit, from some circumstance which will not produce it in another; and yet we may be able to discover no difference between the two individuals. It is the same with all other diseases. We see a predisposition, or an indisposition, to them, unconnected with external circumstances. We cannot tell why, for example, one person will take a contagious disease, or become affected the moment he is exposed to it, while another equally exposed escapes; and so it is, frequently, with regard to epilepsy.

*Exciting Causes.*—If the predisposition be very strong indeed, then the slightest exciting cause will produce it;—such as will scarcely more than quicken the pulse in another person. It has followed tremor;—we find many cases of epilepsy, evidently ascribable to extreme dread. Injuries of the head (not in *one* part merely, but *any* part) will produce it. The suppression of habitual discharges, whether natural or artificial, has the same effect; and so also has the suppression of irritation. It will arise in females from a suppression of the menses; and, in males, from the suppression of an hæmorrhoidal discharge which has become habitual. It arises from the cessation of a mere irritation;—for example, from the cessation of an accustomed cutaneous disease without discharge. The cessation of gout will produce it; and also tumours, especially if situated on the head. These causes, I mentioned, will sometimes give rise to phrenitis.<sup>a</sup> The presence of the tumour produces inflammation of some particular part, so that epilepsy occurs; or the removal of the tumor causes a greater quantity of blood to be thrown on the brain; and thus the disease is induced. It occasionally takes place in violent fever. In fever, the brain is frequently in a state of great excitement; and epilepsy occurs. Sometimes, among other causes, it has been excited by worms in the intestines or stomach, by teething, and even by a stone in the bladder. Irritation of any part of the body whatever, if it amount to a certain point, and the person be predisposed to the disease, may produce epilepsy. In the “*Edinburgh Medical Essays*,” there is mentioned an instance of the disease being produced by a small hard body in a nerve, at the lower end of the “*gastrocnemius externus*” muscle. The disease had existed twelve years; but on this body being removed, it entirely ceased.<sup>b</sup> It is also produced by inflammation of the membranes of the brain: when speaking of arachnitis, or the acute hydrocephalus of children, I mentioned that convulsions were very common.<sup>c</sup> Poison will produce it; mineral poisons (lead, for example,) and all the tribe of

<sup>a</sup> See Pages 492 and 493.

<sup>b</sup> In July, 1720, a woman about thirty-eight years of age, was brought to me [Dr. Short]: She had laboured twelve years under an epilepsy; which, from one fit a month, was come to four or five violent ones every day (each continuing an hour, or an hour a half); by which she was rendered mopeish and silly, and incapable to take care of her house and family. Her husband was reduced in his circumstances, from his affection and care for her;—having got and followed all the advice he could. Evacuations of all kinds had been tried; the epileptic and cephalic tribes of medicines had been ransacked; and many other medicines had been used in vain;—the disease growing more severe. Her fit always began in her leg, toward the lower end of the gastrocnemii muscles; and (in a moment) reached her head, and threw her down;—foaming at the mouth; with distortions of the mouth, neck, and joints. While I talked with her, she fell down in a fit. I examined the leg; and found no swelling, hardness, laxness, or redness, different in that place from what was in the other leg; but—suspecting (from her fit beginning always at that part) that the cause of her disease lay there—I immediately plunged a scalpel about two inches into it; where I found a small indurated body, which I separated from the muscles, and then took up with a forceps. It proved to be a hard cartilaginous substance or ganglion, about the size of a very large pea, seated on a nerve; which I cut asunder, and took out the tumour. She instantly came out of the fit, cried out she was well, and never after had a fit; but recovered her former vigour, both of body and mind.—“*Medical Essays and Observations. Published by a Society in Edinburgh.*” Volume 4 (1735); Article 27. (Fifth Edition; Pages 334 and 335.) See Page 502.

vegetable poisons, will give rise to it.<sup>a</sup> Small-pox will also produce it; it is common for children, at the period of the eruption of small-pox, to have epileptic fits. Dangerous hæmorrhages may produce it. When a person is almost expiring from hæmorrhage, the collapsed state of the brain, from the want of blood, excites convulsions. In some persons, sexual intercourse will produce it. It is said that Napoleon had epileptic fits on such occasions;—not on *every* occasion of the kind; but at periods of particular excitement. Imitation will produce it, especially in females. If they see it in others, they are prone to fall into the same state.

### SECTION III.—MORBID APPEARANCES.

Thus we have just seen, that any violent irritation, whether mental or corporeal, in whatever part of the body it is situated, may produce this disease. Mere inflammation of the brain, or injury of any part of the head, may cause it, when there has been no disposition to the disease before; and it may entirely cease on the cessation of inflammation within the head, or the cessation of any cause of excitement there. On this account, we may frequently expect to find no morbid appearance in the head. As any irritation of any part of the body may produce it, it is not reasonable to suppose that we must in all cases find disease in the head. It may, however, arise from inflammation and irritation of various kinds in the head itself; and, in such circumstances, we may expect to find disease in that part. Now this is just what really occurs. Sometimes, on opening epileptic persons, we find nothing wrong in the brain; even when there has been no evident exciting cause at a distance. When there is an exciting cause at a distance, we cannot expect to find any thing morbid in the brain; but where we can discover *no* exciting cause at a distance,—no stone in the bladder,—no tumour,—no worms in the intestines; but where the cause has been supposed to exist solely in the head,—even in this case the disease has sometimes, and not unfrequently, disclosed nothing after death. It has appeared to be a disease of mere function; and has not produced any structural change. It is always to be taken into account, however, that a great number of persons who open heads, are not qualified to do so;—that is, although qualified to perform the mechanical operation, they are not able to say that every part is perfectly sound. It requires a man to be a good morbid anatomist, and to take great pains, before he examines the head, and declares that there is nothing morbid in it.

But after this disease we find, occasionally, an abscess in the brain, softening of the brain, induration of the brain, or tumours in and upon it. We also find exostosis,<sup>b</sup> thickening, and effusion;—not that the thickening and effusion have been the cause of the disease; but the irritation which produced the epilepsy, likewise produced effusion and thickening. Every disease that is found in the brain, we may find in persons who have been epileptic; because any organic affection of the part may produce the disease. Dr. Prichard (to whose work on *Nervous Diseases* I referred,<sup>c</sup> as being an excellent production) says that he witnessed two dissections, where nothing wrong was seen in the brain. There was a man in St. Thomas's Hospital, who had been there from a boy (having been engaged as surgery boy); and who used to tumble about. I have heard that he was tipsy; but I do not wish to discredit his reputation. When he died, his brain was examined; and, although he was idiotic as well as epileptic, it was said that nothing morbid was discovered. Wenzel, a German anatomist, and others, formed a society for the investigation of cases of this disease,—so far as regarded the *post-mortem* appearances; and they say, that in fifteen cases out of twenty the cerebrum was sound; but the pineal<sup>d</sup>

<sup>a</sup> The most complete table we have seen of these poisons, and of all others, (whether animal, vegetable, or mineral,) and of the diseases which they produce, is that constructed by the late Dr. Fletcher. It is published, as a *Chart*, by Butler, Medical Bookseller, St. Thomas's street, Southwark.

<sup>b</sup> From *εξ*, out of; and *οσσειν*, a bone.

<sup>c</sup> See Page 599.

<sup>d</sup> From *πνεα*, a pine-apple;—alluding to its shape.

gland was diseased, and also the cerebellum; which was altered in consistence, colour, and size; but I have opened persons who have died of epilepsy, and no morbid appearance has been found in the cerebellum, or anywhere else; and, again, the cerebellum is often found diseased, without epilepsy. I believe the truth is, that any irritation whatever will produce this disease; which is nothing more than a great excitement of those parts of the brain connected with the voluntary muscles. It is stated in Dr. Carter's account of a lunatic hospital in France, that one of the physicians there, among the number of lunatics under his care, examined about thirty adult persons, who had been labouring under the disease; and he found no disease of the brain, but only of the "medulla spinalis." These observations were too limited. If sixty had been examined instead of thirty, I have no doubt that the inference would have been different.

*Seat of the Disease.*—Although this disease so frequently arises from a mere functional affection, or a temporary source of irritation, yet it is an infinitely more permanent disease than St. Vitus's Dance, or hysteria; and much more frequently does it arise from organic causes. It arises *less* frequently from structural change than palsy does, but *more* frequently from that source than does either chorea or hysteria. Whatever spot in the whole body is the source of irritation,—whatever spot even of the brain itself (the cerebrum or the cerebellum), it is probably the "medulla oblongata" which is the chief seat of excitement. My reason for arriving at this conclusion is, that pressure on the "medulla oblongata" always causes sleep. This has been ascertained experimentally, in individuals where no other part of the brain existed than the "medulla oblongata;"—the cerebrum and the cerebellum having been deficient. It is said that, in the case of certain fœtuses, if the "medulla oblongata" be *slightly* compressed, we have *convulsions*; but if it be *more* compressed, we have *sleep*; and it is also ascertained, that if a sharp instrument be passed into the brain, there is no sensation felt; but as soon as it reaches the "medulla oblongata," or the *origin* of the nerves (as people sometimes say), we have epilepsy. I think these circumstances make it probable that, whatever the cause of irritation may be, it acts there. However, this is only a probability. It may be the chief seat of chorea, tetanus, and hysteria, as well as of epilepsy.<sup>a</sup>

#### SECTION IV.—DIAGNOSIS AND PROGNOSIS.

*Feigned Epilepsy.*—We have first to ascertain whether the disease is really in existence, or whether it is only feigned. This necessity arises from the fact, that impostors frequently pretend to labour under this complaint; because it looks so frightful, and so much excites the attention of bystanders. In the *feigned* disease, the pupils are not dilated; the nails and the face are not livid; and if their hands be forced open, they are instantly clenched again. In *real* epilepsy, if we force open the hands, they remain so; but if a person be feigning the disease, and we open them, he will close them;—to show that it is real! Some imitate the foaming of the mouth, by putting a little soap under the tongue. Again: in the feigned disease, there cannot be such palpitation and rapidity of the pulse, as in the genuine affection. The impostor, by tossing about, may quicken the pulse; but he will not produce that thumping of the heart against the ribs, which occurs in the real

<sup>a</sup> This opinion is confirmed, in a remarkable degree, by the researches of Dr. Marshall Hall and others, as to the functions of the true spinal cord. These authors have shown, that the closure of the larynx, the distorted vision, and general convulsions, are really a disturbance of the "true spinal" functions; while the coma, and other cerebral symptoms, are really effects consequent upon this disturbance of the spinal functions. Dr. Marshall Hall has divided epilepsy into two principal varieties: the first, arising from direct irritation of the cord itself, he has named "*centric* epilepsy;" the second, arising from irritation of remote organs acting through the medium of the "excitor" nerves, has on that account received the name of "*eccentric, or centripetal*" epilepsy. A knowledge of these distinctions enables us to reconcile the contradictory results of different observers, as to its morbid pathology; and to form a more accurate prognosis in each case.

fit; and in the feigned disease, he does not very well bear putting the edge of our thumb-nail under his, so as to make an attempt to tear the cutis from the nail. A very horrid sensation is produced by this method;—perhaps as sharp an agony as the human body can experience. It is borne in real epilepsy; but in the feigned disease it is found very unpleasant; and impostors take the hand away, or strike the person attempting it. In the feigned disease, they generally take pains to fall down in a comfortable place; they do not fall against the fire or hot bars, or against the edge of a table; and so run the chance of getting a black eye, or lacerating their face. They generally fall down in some convenient place; and, like a cow, lie down steadily and quietly. One other mode of ascertaining the deception, is to propose, in the hearing of the person, some terrible means; such as the actual cautery. If he hears that, and especially if we bring a red-hot poker, he will get up instantly. Many have been detected by talking of some severe means; for the pulse, in consequence of the emotion, will then become quickened, in spite of their efforts to be tranquil.

*Hysteria.*—We may distinguish epilepsy from hysteria, by there being, in most cases, a complete loss of sense; by the absence of globus hystericus, laughing, crying, sobbing, or shaking during the convulsions; and the absence of delirium. Occasionally, hysteria is combined with epilepsy, and then globus hystericus is present; but if it do exist, it is only in a slight degree; and if it exist in no more than a slight degree, we are justified in considering it a case of hysteria, rather than epilepsy. If there be globus hystericus, all the other symptoms of hysteria will be present as well;—laughing, crying, sobbing, and perhaps a copious discharge of very limpid urine. The best mode of making the distinction, is not to depend upon one system, but to take a general survey;—to remember that, in epilepsy, there is usually a *complete* loss of sense; and that, in hysteria, there is only an *incomplete* loss of sense; and, above all, that the fits do not come on regularly before convulsions. Patients will become sensible; and then, in the midst of their sensibility, the disease begins again; whereas epilepsy generally goes on in a pretty regular manner.

*Prognosis.*—If the cause be evident, and is of a temporary and removeable nature, our prognosis would be favourable; but if we cannot discover a cause for it, but see (at the same time) that the cause is not of a temporary nature, or within our power to remove it, then our prognosis should be unfavourable. If we discover the cause, and find it cannot be removed, still of course our prognosis must be bad. The disease, altogether, is one of the most intractable we can have to treat. It is a disease which, in a large majority of cases, cannot be cured; though, in most cases, we may lessen it.

## SECTION V.—TREATMENT.

*Treatment of the Attack.*—If there be aura epileptica, we may frequently stop the disease by putting a ligature between the part from whence it arises, and the centre of the body. In a case of this nature, to which I have already alluded, where there were two auræ,<sup>a</sup> a ligature was placed on each side; and when the patient complained of the sensation, some one tightened them. At last the fits ceased so long, that he went out of the hospital;<sup>b</sup> but I heard, after a still further lapse of time, that they had returned. In the fit itself, there is nothing to do but to place the patient's head high; to put him out of danger, so that he may not knock himself; to loosen his neckerchief; and put a cork or piece of wood into his mouth, to prevent his biting himself. If there be any danger of apoplexy, of course we may bleed; but this is not usually the case. I stated that, in the convulsions of infants, cold affusion had been found to do good;<sup>c</sup> and I do not know that it would do harm. Some persons say they have recovered patients from these fits, by put-

<sup>a</sup> See Page 597.

<sup>b</sup> St. Thomas's.

<sup>c</sup> See Page 592.

ting salt into the mouth. I know that we may frequently recover hysterical women by this means. I have seen them shake their heads, splutter, and open their mouth; but epilepsy is not so soon got rid of. Still, however, it may do some good.

*Removal of the Exciting Causes.*—To speak, however, of the treatment at large, and not of the particular fit. If the exciting cause be evident, we must remove it, if possible. If it be ascertained that there are worms, it is impossible to say whether they are the exciting cause; but it is right to remove them. If there be a stone in the bladder, the operation of lithotomy<sup>a</sup> should be performed. There was a case (rather a celebrated one, I believe) of a man, many years ago, who had received an injury of the head, and in whom epilepsy ensued. A surgeon, at St. Thomas's Hospital, imagined that the removal of the piece of bone might cure the disease;—that a spicula of bone was most probably proceeding from the inner table. A circular piece of bone was removed, by means of the trephine; and there, luckily, was the spicula; and he never had a fit afterwards. The spicula is preserved in the museum at St. Thomas's. I should imagine that a large number of the people who are epileptic, have received an injury of the head; but we might employ the trephine many times, without such a fortunate result. Mr. Wardrop cured a case of epilepsy, beginning with aura in one finger, by amputating the small joint of the finger. Of course, if any other organ than the brain or spinal marrow, be diseased, we should remove it if possible.

*When produced by Imitation.*—The disease frequently arises from mental causes; and there physic can be of no use. We must administer to the state of mind,<sup>b</sup> if it be in our power to do so. The disease once pervaded a whole school, in Holland, in consequence of imitation. One of the boys had epilepsy; and the whole school became epileptic. It was cured there by making an impression on the mind. The boys were all arranged round the room; and were told that the boy who fell in a fit, should be flogged. This put a stop to the disease. I have no doubt that, many times, we might cure *ague* in the same way.

*When succeeding another Disease.*—If the disease have appeared on the cessation of another, we should (if possible) re-excite the original disease. If it occurred after gout and rheumatism, we should apply strong mustard poultices to the joints; but we should also endeavour to lessen an inflammatory state of the head;—notwithstanding we are endeavouring to re-excite the disease at a distance.

*Antiphlogistics.*—Supposing there is no exciting cause to be found, then we may almost always do good, by adopting antiphlogistic treatment. In the first place, it is (generally) useful to insist upon complete abstinence from distilled and fermented liquors;—wine, spirits, and beer of all kinds; and gradually from meat. Persons cannot bear an abstinence from meat well, at first. If any one make the experiment to abstain from it *all at once*, he will find himself grow weak; but if he abstain from it *gradually*, no inconvenience is felt: and a great number of persons can live very well without it. We should also persevere in keeping an open state of the bowels. There should not only be one motion a day, but two. The head should be kept constantly cold, by the use of a shower-bath, and frequent washing of the head. In addition to all this, if the patient be plethoric, venesection, bleeding, and leeches, will be found very useful. Of course, the degree in which all this is done, must be varied in different people; and some persons are too weak to admit of any thing of the kind; but if their state of body will admit of some part of this antiphlogistic treatment, and more especially if it will admit of a great deal, we shall find great alleviation. I know that most persons who go to St. Thomas's Hospital, are *relieved*; but I believe none are *cured*; and I have little doubt that the benefit they derive there, is simply from antiphlogistic treatment. Many are better, before there is time for medicine to have any effect; because they are instantly put on milk-diet, or gruel, or slops. It is to be remembered, how-

<sup>a</sup> Or lithotripsy.

<sup>b</sup> Canst thou not minister to a mind diseased?—"Macbeth;" Act 5; Scene 3.

ever, that this is not to be borne in every case;—that there may be debility; and that a patient may be made worse by a plan of this kind; and even where such treatment is proper, we may make the patient worse by carrying it too far. I have seen many cases, where patients were better to a certain point; and beyond that, by lowering them, they became worse; and then, by going back to that point, they were better again. But even if patients be weak, and we cannot push antiphlogistic regimen to any extent, it is still necessary to avoid stimulants, and those things which cause a flow of blood to the head, and great excitement of that organ.

*Setons, &c.*—Setons, issues, and moxæ, are sometimes useful; but occasionally I have found them useless. The application of tartar emetic ointment at the back of the head and scalp, is a very severe mode of treatment; and I have not found much benefit from it; but, by antiphlogistic treatment, and keeping the bowels open, I have almost always seen great benefit produced.

*Iodine and Mercury.*—There can be no harm in trying mercury and iodine; because there may be some organic disease in the head, which these will remove. There may be irritation; there may be mere chronic inflammation; there may be something to be absorbed; and mercury may do good in such cases. Iodine may likewise do good, as a part of the treatment; but I should not advise one to try it very far. As a part (I may say) of antiphlogistic regimen, mercury and iodine are serviceable. They act by causing absorption; but I am not aware that they do good, except in removing the effects of chronic inflammation.

*Specific Remedies.*—But besides all these things, which may be deemed *rational* treatment, there are certain *specific* remedies in this disease, which we employ *empirically*;—that is to say, remedies which are found to do good without our knowing why. They will not cure the disease, once in many times; but when they do act beneficially, we know not their mode of operation.

*Nitrate of Silver.*—The nitrate of silver is one of these; and no doubt it has done great good. We may begin with the eighth, or the sixth of a grain for a child; but to an adult we may give a quarter, or half of a grain, and increase it to six or seven grains. I think Dr. Fowler says (in a case published in the “*Transactions of the College of Physicians*”) that he once gave fourteen grains, every six hours. I know that when we get to a few grains, it frequently purges too much;—so that we cannot push it farther. It is a remedy which has a tendency to excite gastritis. The salt, or muriatic acid, that may be in the stomach, is decomposed by it; and that is the reason why some people bear a great deal. It has a tendency to act on the mucous membrane of the stomach; and therefore, during its exhibition, we should press on the stomach, to see if there be tenderness. There is no rule for the dose; some will have unpleasant effects from one or two grains, and some will bear five or six with impunity.

*Discoloration of the Skin.*—But, besides these immediate effects, there is another, of a chronic nature. It has a tendency, if it be given for a length of time, to make the skin blue. The decomposed salt is deposited on the surface of the cutis; more and more decomposition takes place; and the cutis becomes black at last;—as though a lead pencil had been rubbed on the surface. We see some persons almost as dark as mulberries; and may fancy that they are going to fall down, from congestion of the head; but they are merely stained by this medicine. It will cause the sclerótica to be blue; but not to the same intensity as the cutis. I have frequently seen the sclerótica nearly of the colour of “*preservers*” (as they are called), which some people wear to preserve their eyes. The nitrate will also blacken the tongue or fauces. It is to be remembered, that a large dose is not required, in order to induce this effect; but that a small dose, if it be continued for some time, will lead to the same unpleasant results. If administered even in minute doses, for so short a time as three months, I believe there is a chance of the skin being blue. It does not so much depend on the *quantity*, as on the *time* that the medicine is given; and, on this account, I think we should be cautious of giving it, in private practice, longer than a month; and, as I do not think a month sufficient to produce any beneficial effects, I seldom use it. If it be *not* given for a long time, it will do

good; and if it be given for a long time, we run the chance of blackening the patient. In the case of young ladies, it should never be given.<sup>a</sup>

*Cupri Ammonio-Sulphas.*—The preparations of copper, (cupri ammonio-sulphas, and sulphate of copper,) will be found, I think, more useful than the nitrate of silver;—little use as any of them are. I have seen benefit result from them. Respecting the dose of these, it is best to give the fraction of a grain; and to increase it gradually. In cases where a large quantity is borne, it may exceed one, two, or three grains a day; and very frequently by no means so much. An over-dose occasions sickness and gastrodynia.<sup>b</sup>

*Iron.*—Iron has been proposed in this disease; but I cannot say that I ever saw it do good. I have no doubt, when a person has been lowered improperly, that it will do a certain amount of good as a tonic; but as to a specific power in the disease, I believe it has none. I had under my care a patient, who had been bled and starved; who had had issues, setons, moxæ, and every other remedy that could be imagined; and who was, in consequence, much debilitated. He then went to some gentleman, who gave him iron; and he told me that it cured him. I have no doubt that he had been reduced too low; and that iron did him good as a tonic; but, six months afterwards, he applied to me again, as bad as ever.

*Acetate of Lead.*—Dr. Rush, of America, states that acetate of lead has very great power over the disease. It is a fact that, in large quantities, it will sometimes cause the disease. Where persons have been poisoned by lead, from taking a quantity into the stomach, or have been much exposed to its exhalations, epilepsy has been produced. Of course that is no argument against its moderate use; but I cannot say that I ever saw any good arise from it.

*Zinc, Arsenic, &c.*—The sulphate of zinc has been much praised, as well as the oxide.<sup>c</sup> I have given it in St. Vitus's dance. It may be exhibited in large quantities;—sometimes twenty or twenty-four grains; but I never saw it do good in epilepsy. The oxide of tin has been much praised; and so has arsenic; but I have seen persons from taking the latter, become epileptic. I do not believe these things are to be depended upon. Narcotics have been praised;—especially stramonium;<sup>d</sup> but I am not aware that they deserve any great recommendation.

*Cold Affusion.*—Cold affusion is certainly of use as a tonic; because it does not excite the patient. There are many tonics which excite the patient, at the same time that they increase his strength; but cold affusion does not. A cold shower-bath is useful in the disease; for it strengthens the constitution, without excitement; and it may knock down excitement by its antiphlogistic effects. It "braces" the body.

*Oil of Turpentine.*—The oil of turpentine is occasionally useful; but far less so than in hysteria. In hysteria, it is an excellent remedy; and if there be worms, in epilepsy, we cannot use a better medicine than oil of turpentine. Dr. Prichard thinks, that if the intestinal canal be diseased, it may do good. In amenorrhœa it may be serviceable; not by exciting the menses, but by removing the state which induces the affection; and so in the case of worms. If it remove intestinal affection, then we cannot say that it is good in epilepsy in general; but it removes the cause in those particular cases. Some contend that it is useful in epilepsy combined with insanity. I believe it has a particular effect on the nervous system; and where it has been said to be beneficial in epilepsy, I should suppose it was where there was some other disease. It has been given in two ways;—in small and repeated doses; and in large and less repeated doses. Twenty drops have been given, two or three times a day; or an ounce every two or three days. Some have given

<sup>a</sup> To obviate this inconvenience, attendant on the use of nitrate of silver, Mr. Lane has recently proposed the substitution of *oxide* of silver;—under the belief that discoloration of the skin will not follow its use. For fuller information on this subject, the reader is referred to the "Medico-Chirurgical Review," for July, 1840 (Volume 33, Page 289); or to Braithwaite's "Retrospect," Volume 1, Page 224.

<sup>b</sup> The usual dose is half-a-grain, in a pill, night and morning.—*Dr. Fletcher.*

<sup>c</sup> The dose of the sulphate is two grains; that of the oxide, ten.—*Dr. Fletcher.*

<sup>d</sup> From "stramen," *straw*;—alluding to its fibrous roots.

a drachm, once or twice a day; but I do not think that, in general, much good is to be expected from it.

*Conditions Favouring the Action of these Remedies.*—All the remedies just mentioned may fail, entirely through our not attending to antiphlogistic regimen. It is possible that cases happen, now and then, that would yield to some of these remedies; but we neglect to lower the patient. I am quite sure that remedies are frequently prevented from doing good, because we do not remove a plethoric state of the system. In some local inflammations, and in many cases of various diseases, it is necessary to lower the system to a certain point; and then remedies, which would not otherwise be useful, become so. The reason that the disease is so generally intractable,—that so many remedies are so uncertain, and so unsatisfactory,—is very evident. This is a disease which arises from every kind of irritation, in every part of the body; and the irritation may be *structural*,—may be slow inflammation, or something we cannot remove. If it always arose from one cause, it would be a different thing; but it will arise from any cause whatever;—physical or mental, organic or inorganic; and situated in any part of the body. Not only, therefore, must it usually be an incurable disease, but there can be no one remedy for it. As to any one medicine being a remedy for epilepsy, I should think a little reflection would show, that it is quite impossible.<sup>a</sup>

## CHAPTER X.

### HYSTERIA.

*Definition.*—In this disease there are fits of general convulsions and insensibility, like epilepsy; but not a continuance of the insensibility after the convulsions are over.<sup>b</sup> For the most part, the convulsions are renewed in the midst of the insensibility. There are also sobbing, crying, laughing, and shrieking in the fit; but particularly before and after it. Sometimes, though not always, there is a mixture of sobbing, crying, laughing, and shrieking, in the midst of the convulsions. The insensibility is, generally, incomplete; the patient having some knowledge of what is going on around, if not all the time, yet during more or less of it. There is also experienced a sense of choking;—as if there were a ball in the throat, which could neither be got down nor brought up; together with irregular breathing; so that there is panting, and the chest heaves up and down. Frequently there is hiccup. Sometimes there is a rumbling noise in the abdomen; and a sen-

<sup>a</sup> Epilepsy is attended by clonic spasms; takes place chiefly in boys; and generally before puberty. The puerperal form of it is the worst; the lightest is that which occurs in small-pox. It begins with "aura epileptica;" the patient falls into convulsions; the hands are clenched; the urine and fæces discharged; the tongue is apt to be bitten, and there is froth from the mouth. These symptoms are followed by sopor. The pulse is not affected till the end of it; and is then accelerated from the violent motions of the patient. In a pretended fit, if you close the eye and open it suddenly, the pupil contracts; and if ammonia be put to the nostrils, it is felt. When called to a person in a real fit, lay him where he cannot hurt himself or others; bleed if you can get an intermission sufficient; dash cold water on him; loosen all the bandages; put cork between the teeth; inject assafoetida into the rectum; put ammonia to the nostrils; and fill the mouth with salt. Cullen thinks it arises from plethora and debility; therefore, after a fit, diminish plethora, and increase the strength. Give mineral tonics, &c. It sometimes ceases at puberty; before that period, therefore, the prognosis is favourable. It is incurable if it arise from a spicula of bone or a tumour pressing on the brain. It is worse if accompanied by aura. A paroxysm is often kept off by fear. Hence horrible remedies were used;—such as drinking blood hot from gladiators.—*Dr. Fletcher.*

<sup>b</sup> Hysteria is also distinguished from epilepsy by the patient's being able to sit on a chair, by the pupils not being affected, by the mind's not being lost (for the patient can understand what is said), and by the absence of frothing.—*Dr. Fletcher.*

sation is experienced as if a ball were rolling to and fro; till at last it comes to the epigastrium, and thence rises to the throat, where it sticks; and then the convulsions begin, and the patient falls down. The abdomen seems to swell; and no doubt it does so. In a few minutes, sometimes, the abdomen will be distended with flatus. There is frequently, also, a great secretion of limpid urine; and this, unfortunately, is sometimes discharged. There is also violent palpitation; just as in epilepsy.

*Frequency of the Fits.*—These fits will come and go in rapid succession. There is not merely one systematic fit, and then all is over; but there is a succession of these fits; and (as I have frequently observed with regard to nervous diseases) one side is often more convulsed than the other.

*Tenderness of the General Surface.*—Occasionally there is extreme tenderness, not during the fit simply, but during the time that women are subject to these fits; and this extends over the whole of the surface. If we press ever so lightly on the chest and abdomen, we find them complain; and the same is felt more or less in the extremities; but it is particularly the case with the trunk; and this has often been mistaken, and no doubt still is, for inflammation.

This morbid sensibility is a very remarkable circumstance; and we may frequently be deceived by it. I confess, I knew nothing about it for many years. Females, with some slight hysterical symptoms, will say they are so tender, that they cannot bear pressure; and such appears to be the fact. The least pressure or friction of the skin gives them agony. Sometimes it extends over the whole body, even to the extremities; and sometimes it is confined to the abdomen.

I am quite satisfied that there is no pretence in all this. I saw one young woman who had been in bed three months in this state. She had been blistered, and leeches; but without any benefit whatever. I saw one young lady, about nineteen, who was lying in bed in this condition. The uterus, I understand, was disturbed; so that she menstruated scantily; and there was fluor albus. Her bowels were habitually costive;—so as to require medicine. There was constant pain of the head, and much tenderness of the abdomen; so that any one would, without care, have thought it was inflammatory. She could not bear the least pressure; and yet there could be no inflammation; for the pulse was only 58, and the tongue clean; and, although there was much pain in the head and eyes, there was no drowsiness, and no intolerance of light. I had hesitation in considering it a variety of hysteria. Some years ago I had, in the hospital, a woman, forty years of age; who, when I touched her, cried out as if I had been going to murder her.

*Delirium.*—Patients, when they are seized with hysteria, are sometimes violently delirious; so that a stranger would imagine there was phrenitis, which required active treatment. It comes on suddenly, however, and there are other hysterical symptoms present. We may generally satisfy ourselves that it is merely hysterical.

*Tetanus, Clavus, &c.*—Sometimes patients have locked jaw;—the mouth being closed; and sometimes they have other tetanic symptoms; but that is the general one. Sometimes, from the violent affection of the voluntary muscles, they have a sensation of extreme pain fixed in some part, called “clavus hystericus;”—a sensation as if a nail (“clavus”) were driven in; and I have no doubt that it is the same as the generally diffused morbid sensibility of the surface; only that it is collected in one spot, and is therefore more acute than when diffused. Sometimes there is catalepsy; which I shall presently notice. There are all kinds of movements of the body, and all kinds of noises made. Sometimes patients will bark like dogs, or imitate various animals.

*Affections of the Joints.*—It is a curious circumstance, mentioned by Sir Benjamin Brodie, that hysterical women, when the paroxysm is over, sometimes have an evanescent stiffness of the joints, attended with heat and pain.<sup>a</sup> In the case of

<sup>a</sup> Sir Benjamin Brodie has published a work specially devoted to hysterical diseases. The title is—“Lectures illustrative of certain Local Nervous Affections.” He says, that “at least four-fifths of the female patients who are commonly supposed to labour under diseases

a young woman, who was seized at church with hysteria, which ended in hemiplegia after she got rid of the fits,<sup>a</sup> one knee was stiff, although applications were resorted to for a month. Sir Benjamin, in one of his lectures published in the "Medical Gazette," mentions the occurrence in the wrist;<sup>b</sup> but, in my practice, I have seen it in various parts of the body. It is usually an evanescent state; but still it is sufficient to prevent the patient from using the parts.

*Mostly occurs in Females.*—This is a disease which occurs much more frequently in females, than males; and in females particularly during their sexual period,—if I may so call it; that is to say, during the thirty years in which they are in their prime; namely, in this country, from about fifteen to forty-five. It must vary in different countries; but in England women menstruate from fifteen to forty-five. If the disease appear at other periods, it is more frequently earlier than later. We more frequently see hysteria in girls who have not menstruated, than in old women who have done menstruating.<sup>c</sup>

*Occasionally in Men.*—But, although this disease is usually seen in females, it is certainly not altogether confined to them; for it will sometimes be observed in boys, and in men under very violent emotions. There is a passage in "King Lear," which refers to this:—

"O how this *mother*<sup>d</sup> swells up towards my heart!  
*Hysterica passio*, down, thou climbing sorrow!  
Thy element's below."<sup>e</sup>

It has been said that this disease can never occur in men, because it is hysteria; but we must not attend so much to the etymology of a word, as to its meaning. The name was given to the disease, from its having been supposed to arise from

of the joints, labour under hysteria, and nothing else." (Page 37.) These Lectures were reported in the "London Medical Gazette;" Volume 19; Pages 197, 246, and 279. (Nos. 466, 467, and 468; November 5, 12, and 19, 1836.)

<sup>a</sup> See Page 614.

<sup>b</sup> Females of nervous and irritable temperament, especially those who have suffered from mental anxiety, are liable to a peculiar affection of the wrist; and, unlike the generality of hysterical complaints, the married and unmarried are subject to it in nearly a similar proportion. The patient complains of a pain in the wrist; which pain, after continuing a certain space of time, is followed by a kind of puffy swelling, extending up the fore-arm, and down to the fingers. This swelling has many of the characters of that produced by synovial inflammation; but differs from it in being more diffused. Sometimes the swelling is extensive; sometimes so slight as barely to be seen. Having lasted some days or weeks, it subsides; while the pain remains, constant in its character, aggravated by every motion, and rendered worse by the patient's attention being drawn to it. To prevent that motion which she dreads so much, the patient keeps her hand in one position; in consequence of which the joint grows stiff and rigid, and the parts assume a very characteristic appearance;—the skin being tense and glossy, and appearing to adhere pretty closely to the textures underneath. The pain may continue for three months, six months, or one or two years; at the end of which time it generally subsides;—leaving behind it a stiffness of the hand and fingers, from which the patient will gradually recover. In one case, however, the pain continued for three or four years; when the hand was left shrunk and withered;—the fingers being contracted and drawn into the palm. The nails had grown lank, scabrous, and rough.

As the health is in general weak, remedies calculated to improve it, are of service to this local complaint; and, in two instances, bark was decidedly of use. From a scruple to half a drachm of the carbonate of ammonia, in the course of the day,—paying at the same time attention to the bowels,—is often a powerful remedy. If the menstruation be irregular, that irregularity is to be corrected by suitable remedies,—as the Vinum Aloës, steel, and similar means. As a local application, the following embrocation will frequently lull the pain:—Misturæ Camphoræ ʒiiss; Spiritus Rosmarini ʒiiss. M. This should be applied tepid, on a rag. A plaster, composed of equal parts of the Emplastrum Saponis, and Emplastrum Belladonnæ, is frequently useful; at any rate, even when it does no good, it can do no harm. The vapour-bath, especially in the advanced state of the complaint, is also a serviceable remedy. At the same time that local or general means are employed, the surgeon should bear in mind one important caution:—never to draw the attention of the patient to her disorder, more than is absolutely necessary.—"London Medical Gazette;" Volume 2; Page 755. (No. 50; November 15, 1823.)

<sup>c</sup> It occurs most frequently in young widows, and next in virgins.—Dr. Fletcher.

<sup>d</sup> See Page 613.

<sup>e</sup> Act 2; Scene 4.

the womb; but the collection of symptoms called "hysteria," will sometimes occur in males;—in boys and young men whose constitution approaches to that of females, and who are susceptible of violent mental emotion.

*Causes: Emotion.*—Any woman may have hysteria, if she can but have emotion of mind strong enough. Epilepsy is a disease which only occurs in certain individuals, as it would appear, from a certain degree of predisposition;<sup>a</sup> but mental emotion will cause more or less hysteria in almost any woman. Anger or grief, especially grief from ungratified desire, or (to use a more elegant expression) "disappointed love," is the most common cause. I presume it is quite as frequent from disappointed *lust*,—in which desire is the only ingredient; as from pure, simple, unrequited *love*.

*Most Common during the Menstrual Period.*—It occurs particularly during the uterine period of life, on several accounts. First, because derangements of the uterus are a very common source of the disease; and (of course) the uterus is not deranged particularly, except during that period. Women do not suffer much in the uterus, till it performs its functions; and very little after those functions have ceased, except in cases of organic disease. It is during the period of its activity, that it suffers particular derangement; and, therefore, during that period, it will suffer particular sensations. Secondly, it is during the period of menstruation, that women fall in love, and have their attachments strongest. Sorrows of all sorts, whether real or imaginary, take place with the greatest severity during that particular period. Thirdly, it is during that period of life, that all the feelings of women are most active. A woman's character becomes altogether developed, when she begins to menstruate; and after the period of menstruation has ceased, all her feelings become more or less obtuse. All our feelings dry up in the decline of life, and we are less susceptible of all emotion. I should suppose there is scarcely a woman who has not had hysteria in some slight degree; such as a choking in the throat; but it is generally a temporary disease, and by no means dangerous. Sometimes it is dangerous, but very rarely so; and, for the most part, it is only temporary. Epilepsy is so obstinate a disease, as to be an "opprobrium medicorum;" but hysteria generally ceases at last, although it may continue for a long time. When we consider that a slight cause is sufficient to produce hysteria in women, we shall see that it must be a temporary affection, and cannot be dangerous. Emotion of mind, costiveness, plethora of the head, suppression of menstruation, or any thing of that kind, will excite it.

*Pathology of Hysteria.*—There can be no doubt, I should suppose, that regular hysteria is situated in the head. The cause may be anywhere; but the disease must be in the head. If a patient is partially convulsed, it may arise from an affection of the spinal marrow; but, in hysteria, muscles that arise *above* the spinal marrow are affected; in addition to which there is insensibility; which, I should suppose, shows that the seat is in the head. We see patients laughing, sobbing, and crying; and then they are suddenly in high spirits again;—so that it certainly must be an affection of the head; only that it arises from a variety of causes, situated in a variety of parts. It very rarely arises from an organic affection in the head, as epilepsy does. As to the other affections,—the palpitation, the faintness, and similar phenomena,—they only show the extent of the affection.

*Treatment.*—The treatment of this disease is for the most part very successful; because there is scarcely a predisposition required for it; and the slightest exciting cause is sufficient to produce it. This is not an "opprobrium medicorum;" but, on the contrary, medical men gain the greatest credit in treating it. Although it would cease spontaneously, you may expedite the cure.

*Treatment in the Seizure.*—The treatment during the fit, should be the same as that for epilepsy.<sup>b</sup> We must set the patient up, and loosen any thing tight about the bosom and neck; and if we find plethora,—so that there is danger of apoplexy,—we should bleed her. The best thing, however, and one that does not answer

<sup>a</sup> See Pages 600 and 601.

<sup>b</sup> See Page 605.

so good a purpose in apoplexy, is to get a pail of water, or a large wash-hand basin full, and throw it strongly upon the patient. She is almost sure to come to. The water requires to be thrown with considerable force; and should not be spared. It is in hysteria that filling the mouth with salt,<sup>a</sup> answers the best purpose. If this be done, the patient generally comes round.

*General Treatment.*—In treating the disease at large, however, we should follow exactly the same plan as in epilepsy.<sup>b</sup> We must, in the first place, look out for any exciting cause; and, if we can find it, remove it (if possible). In the next place, we must adopt antiphlogistic treatment;—provided there be signs of congestion of the head. Many cases of hysteria are cured rapidly by bleeding and purging. There is so frequently mere fulness of the head in this disease, and so frequently does costiveness produce it, that bleeding and purging very speedily (in general) get rid of the disease, or mitigate it considerably. Women are much more subject to costiveness, than men. They are not so particular in these matters; and their pelvis, being large, will hold a great deal; and therefore we continually hear women confess, that they have not had a motion for a week. At charitable institutions, particularly dispensaries,—where patients attend in great numbers,—we find costiveness occurs far more frequently among women than men; and the hysteria will cease on unloading the bowels.

*Ascertain the state of the Uterus.*—It is necessary, in the treatment of this disease, always to inquire into the state of the womb. It was supposed, formerly, always to arise from the condition of the womb; and the name of the disease ("hysteria") comes from *ὑστέρα, the womb*. Hippocrates says, that it occurs only in females; and the idea of its dependence on the womb, is shown by the name which common people give it;—"the fits of the mother."<sup>c</sup> The swelling of the abdomen, and the rumbling noise ascending the throat, were thought to be occasioned by the rising of the womb; and therefore attacks of hysteria were formerly called by the name I have just mentioned. The doctors formerly endeavoured to get rid of the fit, by attracting the womb, and by driving it downwards. They put assafoetida, garlic, and all sorts of disagreeable things into the mouth, to warn the womb to descend out of the way; and put "roses and posies" below, to coax it downwards."<sup>d</sup>

Although the disease frequently *does* arise from the state of the womb, yet very frequently it does not; and therefore, in all cases, we should examine into the state of the womb. If we find amenorrhœa, we should endeavour to remove it by cupping the loins; and when we have done that,—provided the state of the patient will allow it,—we should stimulate the womb by oil of turpentine, and injections of ammonia thrown into the vagina; and, if possible, we should recommend marriage; which is by far the most effectual mode of curing amenorrhœa, in many ladies.

*When arising from Sexual Desire.*—But I believe that where it arises from something connected with sexual desire, the cause is, for the most part, situated in the head. It is astonishing how many young women, with good full bodies, have pain in the head and cerebellum. We have only to ask the question, and we find that the pain is situated there; and I know that by cupping that part well, and purging thoroughly, we may frequently get rid of hysteria, without attending to the womb. The state of the womb is only one cause among a number of others.

*Tonics and Antispasmodics.*—Besides removing any exciting cause that may be present, and removing a plethoric state of the whole body (by bleeding, low diet, and purging,) we find it necessary, in other cases, to do just the reverse;—precisely as I mentioned in epilepsy.<sup>e</sup> These, however, form only a very small

<sup>a</sup> See Page 606.

<sup>b</sup> See Page 605.

<sup>c</sup> See Page 611.

<sup>d</sup> Borborygmus was once thought to arise from gas generated by semen putrefying in the womb. Burnt feathers, and other substances, were applied to the nostrils, to repel the uterus; and aromatics were introduced into the vagina, to tempt the womb.—*Dr. Fletcher.*

<sup>e</sup> See Page 607.

number of cases. It may be necessary to give tonics, (and I think iron is the best,) together with cold affusion and cold bathing. I think the cold bath answers better than any thing else. Occupation is essentially necessary; and, if possible, a good regulation of the mind. For certain symptoms various remedies are useful. For faintness and choking, the fetid gums (although they have been given on a strange hypothesis<sup>a</sup>) are very useful. Assafoetida, by the mouth and anus, is very proper. Camphor and musk are more or less serviceable for the wind following the spasms. Stimulants of various descriptions are often required. For the extreme languor the patient feels, and the extreme sinking of which she complains at the epigastrium, stimulants are absolutely proper; particularly that preparation of iron called "ferri ammonio-chloridum." Some patients complain of experiencing a sensation as if they had no inside. All the tonic medicines that I recommended in epilepsy,<sup>b</sup> are useful; and they will frequently cure the disease. I am sure that the best way of treating hysteria, is to remove any exciting cause that may exist; to get the womb into good order; to prevent all fulness; and, if there be debility, to remove it. Let the patient be in the open air, and occupied; attend to regular exercise; and use the shower-bath frequently.

*Oil of Turpentine.*—To speak of particular symptoms which sometimes attend it. The trismus may in general be got the better of, by a good dose of oil of turpentine. We may throw up two or three ounces by the rectum, or give it the patient to swallow; but the latter is not an easy matter. The jaw generally opens, as soon as the turpentine reaches the intestines; and I have never seen it fail in effecting a cure. Sometimes it has instantly removed the affection, but, in other cases, not for a few hours.

The disease sometimes produces paralysis. I have seen paralysis of the whole of one side (hemiplegia); but it disappeared. I recollect particularly one case of a young girl, who was seized at church. It is very common for patients to be seized at church. I suppose they get excited by the discourse, and by the heat; and sometimes they see persons whom they like very much; but true it is that young ladies are very fond of going into hysterics at church; and they shriek out, disturb the congregation, and put a stop to the service for a time. Now this young woman did so; but there was no pretence in it; and afterwards she was in a complete state of hemiplegia. By dosing her well with oil of turpentine, and bleeding her copiously, she got completely well very speedily. I have seen several of these cases; and they have all done very well. The paralysis is not of a permanent nature, but depends on a temporary state.

I do not know a better remedy for a great number of cases of hysteria, than oil of turpentine;<sup>c</sup> and, to illustrate its efficacy, I may mention the case of a kitchen maid, who was seized with violent convulsions (supposed to be hysterical) and comparative insensibility. She had continued in that state all the day in which she was seized, all the night, and the following morning. I took thirty ounces of blood from her, and purged her with salts and senna; but she still remained insensible, and I then had her brought to St. Thomas's Hospital.—I ordered two ounces of the oil of turpentine; and in half an hour she was perfectly well. It had no purgative effect whatever; but—after she had been insensible for two days and one night, and had been freely bled and purged—a full dose of oil of turpentine restored her completely. The symptoms of insensibility, of trismus, and of paralysis, will give way to this, much better than to any thing else; but it is right to bleed, in many cases, in consequence of the state of the head. The turpentine took no purgative effect, till a dose of castor oil was given; and then it went to work directly. After this she had an attack of paraplegia; but from that she perfectly recovered. I believe, therefore, that in trismus, in hemiplegia, in delirium, and in continual stupor,—provided we have proper recourse to bleeding and purging,—the best remedy is oil of turpentine. In the same class of medicines are the fetid

<sup>a</sup> See the last paragraph but two.

<sup>b</sup> See Page 608.

<sup>c</sup> Ibid.

gums; and, wherever we think proper to employ them, we may employ the oil of turpentine to the same advantage. It has the property of a strong purgative; though it requires to be set off by something else. We may give one ounce first,—to see if that will do; and then follow it up by castor oil.<sup>a</sup>

*Hysterical Irritability.*—Frequently nervous women are in a state of what they call “the fidgets.” They cannot sit still a minute; and the state is exceedingly distressing. Sometimes this is removed by the warm-bath; but it is best combated by mild narcotics. Sometimes I have given opium; and, now and then, I have known prussic acid tranquillize them, when nothing else would; but, in other cases, we find other things do good. The shower-bath, if we can get them to use it, is of great service. Besides this state of morbid irritability of mind and body, they are very perverse, and get great discredit by their bad temper; but I am satisfied it is a morbid state. They are very sulky. I have frequently known them correct the medical attendant, scold, and even swear, and do all sorts of malicious things;—pretending to be worse than they were. I have no doubt all this is a morbid state of mind. Some of these attacks will come on periodically, particularly at the menstrual period; and, when they fall into this extraordinary state, it can only be treated on the same general principles as common hysteria;—removing fulness if there be any, and enjoining the use of the shower-bath.

I have treated those cases of morbid sensibility of the surface, which have fallen under my notice, on the same principle as neuralgia;—supposing them to be an affection of the nerves;—namely, with iron; and they have all done well. I have not found it so in that particular state called “*clavus hystericus*,”<sup>b</sup> where the pain is all felt in one spot; but where the pain is diffused, it is one of the best medicines that can be employed. As to hysteria at large, I do not believe that iron has any power over it. It is only in those cases where there is debility, that it is of use; and then, I presume, it is not serviceable from any specific power over the disease; but as being the best tonic we have.<sup>c</sup>

## SECTION I.—CATALEPSY.

There is a disease which is spoken of separately; but which, I cannot help thinking, is merely a variety of hysteria;—it is called “catalepsy.”<sup>d</sup>

*Symptoms.*—In this form of the affection, the voluntary muscles will take on any state that we think proper to give them; and so they will remain. We may mould the body into any form we choose. Consciousness and perception are sometimes entirely destroyed; and sometimes only partially so. Frequently the person is not aware of her existence, or of what is going on around;—consciousness and perception being both absent. Dr. Gregory<sup>e</sup> used to speak of the case of a lady, who had undergone great mental anguish. Her history, he said, was like that of Isabella, in the tragedy of the “*Fatal Marriage*,” and she was seized with catalepsy. If her child was presented to her, she gave signs of knowing it; but that was the only proof she exhibited of the least consciousness.<sup>f</sup>

*More Frequent in Women than Men.*—It is a disease which occurs more frequently in women than men;—just as hysteria does;<sup>g</sup> but, like hysteria, it sometimes occurs in males.<sup>h</sup> There is a case mentioned by Bonet, of a deserter who was captured, and when taken shrieked violently; and who then entirely lost his voice, from the violent mental emotion. He was a man of no great courage. He became immovable and unconscious, and then fell into catalepsy;—so that they could mould him into any thing. This man neither ate nor drank, nor did he discharge his fæces or urine for twenty days; at the end of which time he sank.

<sup>a</sup> Hysteria may be kept off by affections of the mind, particularly ridicule.—*Dr. Fletcher.*

<sup>b</sup> See Page 611.

<sup>c</sup> See Page 608.

<sup>d</sup> From *καταληψαν*, to seize.

<sup>e</sup> See Note to Page 239.

<sup>f</sup> “*Walking catalepsy*” is somnambulism coming on in the day.—*Dr. Fletcher.*

<sup>g</sup> See Page 611.

*Sometimes Periodical.*—Occasionally the affection has been periodical. Dr. Heberden mentions, in his "Commentaries," that he once saw at St. Thomas's Hospital a case, which he visited from curiosity. The woman was thirty-six years of age; and had a paroxysm of catalepsy morning and evening. It usually continued from one to three hours; but, on one occasion, it lasted *twelve* hours. The fits came on without any warning; and during them, he says, the pulse and the breathing were natural; the eye was fixed, as if she were looking attentively on some object; the arm continued as it was placed, for twenty minutes together, and once for a whole hour; and he was told that it would sustain a weight of seven pounds, in any posture in which it was placed. The jaws were closed; but if the nostrils were closed, then the mouth opened for the purpose of breathing. A slight winking was noticed, on approaching the finger to the eye; and a little contraction of the iris.<sup>a</sup> There was a case in St. Thomas's Hospital a few years ago. It came on in paroxysms at one certain period; but it was not under my care. It occurred (as hysteria so often does<sup>b</sup>) in a girl. The symptoms of the disease are not always regular. It is sometimes impossible to mould patients. They are perfectly rigid; and we can lay them out like corpses.

*Prognosis.*—This disease is not necessarily dangerous,—any more than hysteria;<sup>c</sup> but it appears, now and then, to have proved fatal; or, at least, that state of the system in which it occurred, has proved fatal. Such a case is mentioned by Dr. Gooch; and has been published in the "Transactions of the College of Physicians."<sup>d</sup>

<sup>a</sup> On the twenty-sixth of June, 1764, in St. Thomas's Hospital, I saw a woman six-and-thirty years of age, motionless, with a fit of the catalepsy. Her pulse was quite natural; her breathing easy. Her eyes were fixed,—as by attentive contemplation;—not like those of a person who is either dying, or sick, or under any pain or uneasiness. Her limbs always retained the situation in which they were placed by the bystanders,—however inconvenient. I extended her arm, and saw it remain stretched out for twenty minutes; and I was told it continued so, on a former trial, above an hour; which scarcely any body in health could support. I heard even that it would remain extended with a weight of seven pounds in the hand. If the patient was placed upright, she continued upright; and was not very easily thrown down. While she was sitting down, both the legs were extended, and raised from the ground; and they remained in that uneasy posture; as if they had been made of clay or wax. Her mouth was closed; and I was unable by any means, to open it. The eyelids were constantly open; or, if forcibly closed, they opened again as soon as the force was removed. She winked, but in a very slight manner, upon moving the finger quick towards the eye; at other times the eyelids did not move. At the approach of a candle the pupil contracted. If the nostrils were compressed, after a little effort, and apparent struggle, the lips opened for the purpose of breathing. I heard that she had been in this state some months. The fit returned morning and evening, almost every day; and continued sometimes an hour, at other times three hours. The nurse reported, that one fit had lasted twelve hours. She used to be suddenly seized, without any previous notice.—"*Commentaries on the History and Cure of Diseases. By William Heberden, M.D.*" Chapter 69. (Page 361 of the First Edition.)

<sup>b</sup> See Page 611.

<sup>c</sup> See Page 612.

<sup>d</sup> Mrs. — is twenty-nine years of age; and has long been unusually subject to the common forms of hysteria. I [Dr. Gooch] have seen her, after being strongly excited in conversation, sink down insensible; and, a few minutes afterwards, recover with choking and sobbing. Her husband tells me, that he has often seen her, while sitting at the dinner-table, become apparently insensible, with her eyes open, and still sitting up;—continuing in this state several minutes, and then coming to herself again; but totally unconscious of what had taken place in the interval. She married nine years ago; has been pregnant many times, but has only borne one living child; every other time, she has either miscarried during the early months, or (what was more common) the child has died, without any obvious cause, about the sixth or seventh month, and premature labour has come on about a week or two afterwards. A few days after her last delivery (of a dead child at the seventh month),—a circumstance attributed to some domestic agitation,—she was seized with a violent aching of the head and face,—confined to the left side, and subsiding under the use of hemlock; but she continued to suffer flatulence of the stomach, had a quick weak pulse, and was much depressed in spirits. One evening, she told her husband, that she had never discharged the duties of a wife as she ought to do; and that her death would be a happy release, both to him and her; the next morning, she made an unsuccessful attempt to cut her throat. I now saw her, in consultation with a physician of extensive experience in these diseases. She was put under the care of a regular attendant; and was at times so violent, that it was

*Diagnosis.*—It is necessary in this disease, just as in hysteria and epilepsy, to ascertain whether the case is real. We are told that John Hunter discovered that a case of this disease was feigned, by putting a string round the wrist of a patient, after the arm was extended, and appending a weight to it. The string was suddenly cut; and, as the man had then no weight to support, the arm was immediately raised. It appeared to John Hunter, that the man had sustained the weight by the exertion of his muscles; and the throwing up of the hand after the string was cut proved the correctness of that opinion.<sup>a</sup> Another device has been, to throw the patient into a cistern of cold water. If the disease be genuine, it is supposed that the patient will go to the bottom; but that if not, she will make an effort not to be drowned, and will struggle about. I should not, however, consider this any proof; because nothing is so good in hysteria, as throwing a woman into cold water. Therefore, in catalepsy, plunging the party in cold water, is likely to stop the paroxysm; and, if the paroxysm be stopped, then the person may struggle about, and yet not be an impostor.

It is said, however, that a very ingenious mode of discovering whether the disease was feigned or not, was put in practice by a physician (or at least by a *practitioner*) in the East. Pocock mentions, in his travels, that a case of this disease occurred in one of the favourites of a celebrated caliph; or, at least, that one of his favourite damsels pretended she was in this condition. Pocock says there was general sorrow throughout the palace; the women all sobbed; the eunuchs all groaned; and the Dey was distracted. He sent for all the royal physicians, ordinary and extraordinary. They used stimulants and warm fomentations to soften the

necessary to confine her with a waistcoat. A few days after our first visit, we were summoned to observe a remarkable change in her symptoms. The attendants said she was either dying, or in a trance. She was lying in bed, motionless, and apparently senseless. It had been said, that the pupils were dilated, and the iris without motion; and some apprehensions of effusion on the brain had been entertained; but, on coming to examine them closely, it was found that they readily contracted, when the light fell upon them. Her eyes were open; but no rising of the chest, no movement of the nostrils, no appearance of respiration could be seen; the only signs of life were her warmth and pulse. The latter was (as we had hitherto observed it to be) weak, and about 120: her faces and urine were voided in bed. The trunk of the body was now lifted,—so as to form rather an obtuse angle with the limbs (a most uncomfortable posture), and there left with nothing to support it. There she continued sitting, while we were asking questions, and conversing;—so that many minutes must have passed. One arm was now raised, then the other; and where they were left, there they remained. It was now a curious sight to see her sitting up in bed, her eyes open, staring lifelessly, and her arms outstretched; yet without any visible sign of animation: she was very thin and pallid; and looked like a corpse that had been propped up, and had stiffened in that attitude. We now took her out of bed, placed her upright, and endeavoured to rouse her by calling loudly in her ears;—but in vain. She stood up; but as inanimate as a statue. The slightest push put her off her balance; no exertion was made to regain it; and she would have fallen, if I had not caught her.

She went into this state three several times. The first time, it lasted fourteen hours; the second time, twelve hours; and the third time, nine hours;—with waking intervals of two days after the first fit, and one day after the second. After this the disease resumed the ordinary form of melancholia; and, three months from the time of her delivery, she was well enough to resume her domestic duties.—“*Medical Transactions, published by the College of Physicians in London.*” Volume 6; Pages 266 to 270.

<sup>a</sup> A patient in the hospital [St. Bartholomew's] feigned to be afflicted with catalepsy; in which disorder, it is said, a person loses all consciousness and volition; yet remains in the very attitude in which he was suddenly seized with this temporary suspension of the intellectual functions. Mr. Hunter began to comment, before the surrounding students, on the strangeness of the latter circumstance; and, as the man stood with his hand a little extended and elevated, he said—“You see, gentlemen, that the hand is supported, merely in consequence of the muscles persevering in that action to which volition had excited them, prior to the cataleptic seizure. I wonder,” continued he, “what additional weight they would support!” So saying, he slipped the noose of a cord round the wrist, and hung to the other end a small weight; which produced no alteration in the position of the hand. Then, after a short time, with a pair of scissors, he imperceptibly snipped the cord. The weight fell to the ground; and the hand was as suddenly raised in the air, by the increased effort which volition had excited for the support of the additional weight. Thus was it manifested, that the man possessed both consciousness and volition; and the impostor stood revealed.—“*Hunterian Oration for the Year 1819. By John Abernethy, F. R. S.*” Pages 58 and 59.

limbs, but all in vain; when a man, who had cured the grand vizier (the prime minister) of some secret disease, was recommended to the Dey. This man was named Gabriel; and he obtained a promise, that no offence should be taken at whatever plan he adopted to cure the lady. Being thus himself secure, the lady was brought into the presence of the court, with all the women around her, and covered with a fine muslin robe, flowing down to her feet. Gabriel ran up to the lady boldly; seized the hem of her garment; and endeavoured to raise it,—so as to expose her person. The lady modestly put down her hand to prevent the insult; when he immediately turned round to the caliph, and said—“O defender of the faithful, so and so is cured.” Here was a case of complete deception, from the beginning to the end; and the poor man devised this ingenious means for detecting the cheat.

*Treatment.*—With regard to the treatment of the disease when it is real, I believe the best mode is to adopt exactly the same plan as in common hysteria.\* In the paroxysm we should dash cold water on the patient; and give her oil of turpentine, either by the mouth or the rectum. We should purge the patient well; and, if possible, remove any source of irritation that may be present. There are cases which, I have no doubt, will be best remedied by antiphlogistic measures, and the removal of plethora. On the other hand, there are cases which will be best treated by tonics. I have never had to treat a case; but, from what I have seen in other instances bordering upon it, I have no doubt that the same treatment as that employed in common hysteria, would answer very well.

## SECTION II.—TRANCE.

*Symptoms.*—One of the curious forms of hysteria is long-continued insensibility, which is called “a trance.” Sometimes there is continued insensibility for a few days or weeks; and sometimes for *many* weeks. Sometimes patients will eat, if food be put into their mouths; and sometimes not. Sometimes they will wake for a few hours, or perform certain actions, show some power over volition, and then fall into the same state again. Some will open their eyes, and then fall asleep again. Some, in this state, are perfectly conscious of what is going on around them; but cannot make the least effort.

There is an instance mentioned of a female (for these strange things generally occur in females) who was presumed to be dead. Her pulse could not be felt, and she was put into a coffin; and, as the coffin lid was being closed, they observed a sweat break out, and thus saw she was alive. She recovered perfectly; and then stated, that she had been unable to give any signs of life whatever; that she was conscious of all that was going on around her; that she heard every thing; and that when she found the coffin-lid about to be put on, the agony was dreadful beyond all description;—so that it produced the sweat seen by the attendants. I have seen a case of this extraordinary insensibility, where the patient continued for two or three weeks (with the exception of short intervals) in a state of insensibility, though not without signs of life; for the heart was still beating; and sometimes she performed, in this state, certain voluntary actions, and would afterwards be conscious of having done so. Sometimes she would be unable to do any thing, and yet retain her consciousness;—so as to mention it afterwards.

[There is another state of stupor or coma, in which the mind is entirely cut off from intercourse with the external world. This occurs in the worst states of fever, and in various diseases of the brain and injuries of the head; and the same condition takes place, from a very different cause, in the state of fainting. In such cases, there is seldom any recollection of mental impressions; yet there are facts which tend to show, that the patient is not in such a state of total insensibility to external things, as his appearance would indicate. Facts are wanting on this curious subject;

\* See Page 613.

but there can be little doubt, that many of the stories related of things seen by persons in a state of trance, are referable to this head; and that their visions consisted of the conceptions of the mind itself, believed for the time to be real, in a manner analogous to dreaming. That such impressions should not be more frequently remembered, in ordinary cases of stupor, probably arises from the higher degree and greater permanence of the affection, than of that which occurs in sleep. For we have reason to believe, that dreams which are remembered occur only in imperfect sleep; and that after very profound sleep, we do not remember any mental impressions, though we have satisfactory proof that they exist. Thus, a person will talk in his sleep,—so as to be distinctly understood by another; but without having the least recollection of the mental impression which led to what he said.<sup>a</sup>]

*Sometimes Fatal.*—Hysteria, in these irregular forms, although for the most part a disease without danger, may become fatal. Two sisters were affected in the same way; one of whom died before I saw her; and I went to see the other. Although she was well supported every hour, as she lay apparently a corpse; yet I believe she sank at last. The other was a case of regular hysteria; and I concluded the patient would do well under ordinary treatment; but all at once she sank. Swelling of the hands came on, the pulse became weak, and she died; but *why*, I cannot tell; for I could not obtain leave to open the body.

### SECTION III.—LETHARGY.

When consciousness and voluntary motion only are suspended, and a state resembling sleep is produced,—differing from it in being more prolonged,—the affection is termed “lethargy,” and (by some writers) “cataphora.” This is only another form of catalepsy; but it is not necessarily, though it is occasionally, complicated with hysteria. A case is mentioned in the “Philosophical Transactions” for 1694, of a man, twenty-five years old, residing near Bath, who slept nearly a month in a state of lethargy. In two years, he again fell into an inordinate sleep. At first, he ate, drank, and discharged his urine and fæces; but at length his jaws set; and he ate nothing more, and did not awake for seventeen weeks. It so happened that the barley was being sowed when he fell asleep, and when he awoke it was being reaped. In August he fell asleep again; and was bled, stimulated, and treated *secundum artem*; but did not wake till November. The termination of the case is not given.

It is recorded, in Plott’s “Natural History of Staffordshire,” that a woman slept forty days. In the “Medical Observations and Inquiries,” there is an account of a woman who slept seventeen or eighteen hours, every day, for fifteen years. Dr. Good mentions seeing a lady, who was only in the habit of waking for one or two hours, two or three times a week, during the summer.<sup>b</sup> I believe an affection of this description is not dangerous. I have heard (but I do not know the particulars of the case) that there has lately been an extraordinary person of this description, who was in the habit of sleeping for weeks together. The only cases of the kind that I have seen, have been trances;—those affections of a hysterical nature, which I have already mentioned.<sup>c</sup>

*Sometimes Fatal.*—Although this disease is usually not of a dangerous cha-

<sup>a</sup> “Inquiries concerning the Intellectual Powers. By John Abercrombie, M. D.” Part 3; Section I; Sub-section 5, Head 5. (Ninth Edition; Pages 144 and 145.)

<sup>b</sup> I was some years ago acquainted with a very singular example, that continued for five years. The patient was a young lady of delicate constitution, in her eighteenth year at the time of the attack; her mind had been previously in a state of great anxiety. The remissions occurred irregularly, twice or three times a week; and rarely exceeded an hour or two. During these periods she sighed, ate reluctantly what was offered to her, had occasional egestions, and instantly relapsed into sleep. Her recovery was sudden; for she seemed to awake as from a night’s rest, by a more perfect termination of the paroxysm, not followed by a relapse.—“*Study of Medicine*,” Class 4; Order 4; Genus 8; Species 4; Variety 2.

<sup>c</sup> See Page 618.

acter, Dr. Willan mentions, in his "Reports of the Diseases in London," that lethargy is very common among the Jews of this town; and that it frequently ends in fatal apoplexy.<sup>a</sup> Occasionally, after fever, persons will sleep for a very considerable time. Willis mentions a case of putrid fever, which terminated in a perfect sleep of four days; and, at the end of that time, the man was imbecile for two months. Mr. John Bell (the surgeon) saw a man who, in consequence of a fall, lay a great length of time in a sleep of this description; and when he awoke he was incoherent; but he finally recovered.

## CHAPTER XI.

### DISEASES OF MOTION.

#### SECTION I.—PARALYSIS AGITANS.

*Definition.*—The first disease of this description which I shall notice, consists in a very slight tremulous motion; and is called "*paralysis agitans*," or (in common language) "shaking palsy." It is defined to be an involuntary, chronic, tremulous motion of more or less of those parts of the body which are subject to volition, together with lessened muscular power; occurring in parts when they are not in action, and even when supported; together with a tendency to bend the trunk forwards, and to pass from a walking to a running pace; the senses and the intellect being uninjured. Tetanus affects the voluntary muscles; but palsy does not affect them, like tetanus, with spasms; but with minute convulsions called "tremors;" alternating perhaps with relaxation, and quite involuntary. Not only are the motions involuntary; but the patient has not the same power in producing voluntary motion, that he has in tetanus. It is not the tremor which a person who has been intoxicated the night before, or has taken a cup of strong coffee or tea, shows when going to put the glass to his head;—shaking it till he spills the contents; but there is a tremor when the parts are still; and even supported. Of course, when we run, we make a much greater voluntary effort, than when we walk. The faster we run, the greater is the effort we make, and the more powerful and steady is the motion. We can therefore conceive, that, by a strong effort, the patient is more likely to overcome involuntary motion, than if he be only exerting half the volition; so that persons in this disease are not to be interrupted, and are constantly on the trot (as it were).

*Progress of the Disease.*—The muscular weakness and tremors begin, generally, in some one part of the body only;—for instance, in the head; but most frequently they begin in the hand or in the arm; and perhaps it is not till after some months, or even some years, that another part is affected. But the disease frequently increases both in degree and in extent; more parts become affected; and parts affected before become more affected; till, at last, the whole body shakes. Like St. Vitus's dance,<sup>b</sup> it may be checked for a moment, or a few moments, or even to the extent of a minute, by a violently strong voluntary effort; but it soon returns. The patient becomes less upright, bends forwards, walks upon his toes, and steps quick and short; till at last he comes (as I stated in the definition<sup>c</sup>) almost to a running pace. If the disease remit in one part, it generally increases in another; so that if both arms tremble, and one is improved, the other will im-

<sup>a</sup> Lethargy is not a frequent disease among our own countrymen [the English]. I have seen it mostly in Jews, and other aliens of a dark, swarthy complexion; who sometimes lie six or eight weeks, in a torpid insensible state.—"*Miscellaneous Works of the late Robert Willan, M. D.* Edited by Ashby Smith, M. D." Page 339.

<sup>b</sup> See Page 622.

<sup>c</sup> See the previous paragraph.

mediately shake in a twofold degree. This, we shall see, is also the case in St. Vitus's dance.<sup>a</sup> A change of posture will sometimes disturb the action that is going on. This tremulous motion ceases during sleep;—the same as in St. Vitus's dance; unless the case be very severe, and has continued for a long time; for then the tremors will continue even during sleep. At length the muscles of articulation, mastication, and deglutition, become affected; and, finally, the urine and feces are discharged involuntarily. Such is the loss of muscular power; and, in the midst of all this misery, the patient becomes emaciated, and death generally supervenes.

However, sometimes the disease does not extend at all. Many persons have shaking palsy of the head, for several years, without any other part shaking, and without any increase in degree. This is a disease which frequently attacks persons in the decline of life. There is a curious instance mentioned by Mr. Parkinson, in which hemiplegia occurred, and the paralyzed parts ceased to shake; but when the hemiplegia ceased, then the shaking returned.

*Diagnosis.*—We have to make a diagnosis between this disease, and the tremor induced by drunkenness, or violent passion, or that which occurs in delirium tremens. The tremor, in these cases, occurs particularly when an effort is made, and is not lessened by an effort. It is not lessened by support; and generally the cause is obvious. Many old writers have made this distinction;—Galen, Sauvages, and others; yet I believe paralysis agitans was not well characterized, until Mr. Parkinson wrote his pamphlet on it, in 1817.<sup>b</sup>

*Pathology.*—Mr. Parkinson gives only one post-mortem examination; and that was a very severe case, where the disease was universal; where there was great muscular debility, impediment of speech,<sup>c</sup> and (at last) impairment of intellect. He found, in that case, the lingual and brachial nerves tendinous;—that is to say, greatly indurated; the “medulla oblongata” and “pons varolii” were very compact and large; and the “medulla cervicalis” (the cervical part of the spinal marrow) was hardened.

*Treatment.*—This is a very obstinate disease; and I have no doubt its obstinacy arises, generally, from there being an organic affection. Mr. Parkinson imagines the disease to exist in the superior part of the cervical “medulla spinalis,” extending upwards to the “medulla oblongata;” and he suggests antiphlogistic measures, directed particularly to this part. I have not been, by any means, successful in the treatment of this disease. When it occurs in old people, (where the head, or one hand shakes,) I have never known good to be done. Where it has occurred generally, I have never been able to cure more than one case; and, in that instance, the patient was not more than five-and-thirty years of age, and I am satisfied there was no organic disease; whereas in old persons, I should think, there is organic disease;—probably induration; or, at least, a process going on which *leads* to induration. This man, who was in the middle period of life, was not likely to suffer from structural change, unless induced by inflammation. There was pain and heat of the head, and giddiness; and, therefore, I treated him antiphlogistically. I bled him well, blistered, mercurialized, and starved him; and he had setons introduced: but all without any benefit. Finding, after a long trial, that the plan did no good, I gave him zinc: which is a very useful remedy in St. Vitus's dance. He took a considerable quantity, three times a day; but without any benefit; and I then exhibited sesquioxide of iron, under the employment of which he became perfectly well; and remained so for some time afterwards. I have since had four or five cases of the disease under my care, and have exhibited the same medicine; but it

<sup>a</sup> See Page 622.

<sup>b</sup> “An Essay on the Shaking Palsy. By James Parkinson.” It is the best work that has been written on the subject.

<sup>c</sup> Palsy of the tongue is often a local disease, arising from an affection of the ninth pair of nerves (“lingual”);—causing stammering, &c. It may be caused by a stroke of lightning, and might be cured by another; and the same observation applies to galvanism; which, together with strong gargles (as of cayenne-pepper), is the best remedy. The general affection occurs chiefly in old persons who have laboured much with poor diet. The best plan is to give tonics, and apply blisters to the spine.—*Dr. Fletcher.*

has not produced the least benefit. Most of the cases remained unaffected by the remedy. One or two were certainly a little improved, for a time; but nothing farther.

*In Young Persons.*—Now and then, the disease occurs in young persons in a transient slight form, not connected with any organic affection; but appearing to be in females an hysterical affection, and in males to depend on congestion of the head. I have seen several young adults, who have had a shaking of one arm or hand; which has been cured by purging them frequently, and using antiphlogistic remedies directed particularly to the head. We may cure that form of the disease very well; but when it occurs in the decline of life, I have hitherto found it incurable.

## SECTION II.—CHOREA.\*

*Definition.*—The next disease which I shall notice, is very much allied to paralysis agitans;<sup>b</sup>—so far as it consists of irregular, slight, convulsive motions; and is unattended by any serious disturbance of the intellect, unless it continues for a very great length of time; but it is one which occurs, on the contrary, in young persons. It is called “St. Vitus’s Dance.”<sup>c</sup>

*Symptoms.*—This disease is characterized by a catching of the fingers and other joints, a twitching of the head, corrugations and contortions of the face, very extensive flexions, extensions, and rotations of the extremities;—in short, by perpetual motion, with a rolling of the eyes. The patient is observed, in the first instance, to drag one foot; and, frequently, there are such catches of the tongue, and of the muscles of the neck and throat, that articulation, deglutition, and mastication, are difficult; and so likewise is walking, standing, sitting, or lying. I have seen the skin of the chin and breast rubbed off, by the perpetual scraping of the one on the other. I have sometimes seen the patient, unable to lie on the bed, rolling off it; so that it was necessary to strap him down. These, however, were very severe cases. It is often very difficult to feed patients. It will sometimes require the aid of two or three people, to give them their meals:—two to hold them still, and one to catch the favourable opportunity of putting the spoon into their mouths. The motion is increased temporarily by fear, or any mental emotion. Nothing is more common than for the motion to increase when a medical man appears. Any mental agitation will have the same effect. If a child be made cross, the motions will be doubled almost directly. These motions are a little under the power of the will: persons can restrain them temporarily, but their best effort in the disease is little more than a sudden catch.

Persons walk quickly better than slowly; and Dr. Heberden mentions the case of one individual, who could not *walk*, though he could *run*;<sup>d</sup>—exactly as in paralysis agitans.<sup>e</sup> The movements are suspended during sleep, unless in extreme cases. If we hold one part, then another is agitated the more; and, generally, one side is more affected than the other. This is very common in all convulsive diseases; and, indeed, in diseases of *sense* as well as of *motion*. In many of these diseases, it is common to see only one side affected; but where both are attacked, it is usual to see one more affected than the other. This circumstance occurs in St. Vitus’s dance; and the side most affected will, in the progress of the disease,

\* The Latin word “*chorea*,” comes from the Greek word *χορεία*. There is the best authority for calling it “*chorea*,” and not “*corea*.” The latter word has been used; but only by a poetical license: the proper one is “*chorea*.”

<sup>b</sup> See Page 620.

<sup>c</sup> See Page 626.

<sup>d</sup> A boy had his leg so violently agitated, that the involuntary motions overpowered all his weaker efforts of his will to move them; but a stronger exertion of the power which excites spontaneous motions, was able to control his distempered agitations;—so that he could *run*, but could not *walk*: the same is observable in men intoxicated, to a certain degree, with strong liquors.—Dr. Heberden’s “*Commentaries*,” Chapter 20.

<sup>e</sup> See Page 620.

frequently change;—so that the *right*, at one time, shall be most affected; and, at another, the *left*.

One leg and one foot generally first show the disease. The arms are generally more affected than the legs. The face has very frequently a fatuous appearance: the mind is apparently a little affected; and persons are certainly a little childish in this disease. The pulse is sometimes very quick, when the motions are very rapid; and sometimes there is headache, heat of the head, vertigo, and drowsiness. Sometimes patients will scream, and even epilepsy will come on; and sometimes there is hardness of the abdomen; but, in a large number of cases, we find nothing the matter with the patient, except this extraordinary movement. We may meet with additional symptoms; but, in a great number of instances that I have seen, such has not been the case.

*Duration.*—The disease may last some weeks, or some months; and may then disappear;—either spontaneously, or as the result of treatment. Now and then it continues during life; but the majority of patients recover, and even regain their looks. The fatuous aspect of countenance, and the imbecility of mind, disappear. In a local form, this disease will continue for life. Many persons always have a catching of one leg, or one arm; or a catching of some of the muscles of the face. Some are always winking; some run with their head forwards, like a goat; and some throw their head down;—so that they have been a great inconvenience to auctioneers, who imagined they were bidding. There are many persons, with these unfortunate local forms of the disease. When it is so local, it almost always continues for life; and it often runs in families. I have observed, that where one part of a family has these catches, another has something else peculiar in the nervous system. That is very common.

*Termination.*—When the disease occurs in adults, I believe it is seldom cured. It is where it occurs universally, and in very young adults, that it is cured. It is hardly a proper mode of speaking to say, that the disease may terminate fatally; but that state of the nervous system which produces it, may end in death. I recollect a case, in a strapping girl about nineteen, which ended fatally. She did not die of St. Vitus's dance, but of apoplexy. The congestion of the head, which in one degree produced chorea, in another gave rise to apoplexy; and pathologically it could not be said she died *of* the disease, but *in* the disease. It was an affecting circumstance; and I have no doubt might have been prevented, had she been well bled and purged.<sup>a</sup>

*Usual Period of its Occurrence.*—This is a disease which occurs, chiefly, between three or four years of age, and fourteen. Dr. Heberden says it is most frequent between the ages of *ten* and *fifteen*;<sup>b</sup> but my experience leads me to say, from *three* or *four* years to fifteen.

*More Frequent in Girls than Boys.*—It occurs, too, more frequently in girls than in boys. Dr. Heberden says, that one-fifth only of the patients under his care were males;<sup>c</sup> and that has been about the proportion I have met with; at least, in 1826, I looked over my cases of this disease; and found that, in the hospital,<sup>d</sup> I had had seventeen patients altogether; and twelve of them were girls, three were boys, and the rest were adults. I may mention that, at the same time, I looked over my cases of epilepsy; and found they were just the reverse;—that out of twenty-five cases of epilepsy, nineteen of the patients were males. Dr. Heberden made the same observation.<sup>e</sup> In 1829, I had (altogether) thirty patients labouring

<sup>a</sup> See Page 624.

<sup>b</sup> See the twentieth chapter of his "Commentaries." He adds:—"It has come on so early as the *sixth* year, and so late as the *twentieth*."

<sup>c</sup> Among the patients I have attended, there have been four times as many girls as boys.—Dr. Heberden's "Commentaries;" Chapter 20.

<sup>d</sup> St. Thomas's.

<sup>e</sup> One would expect, that the weaker sex would be greater sufferers by epilepsy; but it has appeared to me, that though boys and girls be equally subject to epileptic convulsions, yet fewer women are afflicted with them than men.—Dr. Heberden's "Commentaries;" Chapter 33.

under St. Vitus's dance; and twenty-two of them were females, and eight males;—about the same proportion as in 1826. With respect to epilepsy, out of thirty-seven patients, in 1829, twenty-seven were males.

*Causes.*—The tendency of this disease is constitutional. I do not know that it is hereditary; because adults, frequently, cannot tell whether they had St. Vitus's dance when they were young or not; but it is very common to see two or three children in a family have it;—not at the same time, but at different periods. It affects all sorts of children;—those who are pale and sickly, and those who are ruddy. It frequently affects those who are otherwise in perfect health, and generally there is no obvious cause, either predisposing or exciting. All I can make of it is, that it is a morbid excitability of a certain portion of the centre of the nervous system, (the “medulla oblongata,” or spinal marrow,) with which the nerves of voluntary motion are connected; but not a sufficient irritation to produce that violent action which characterizes tetanus. As to its being inflammatory, almost every case may be cured, not by antiphlogistic measures, but by those which are just the reverse. It has been said to arise from an irritation of the alimentary canal; but I am quite sure that, in nine cases out of ten, (I might almost say *nineteen* out of *twenty*,) the alimentary canal is healthy. If the cure arose from purging, the feces would be unhealthy. Now and then a distant exciting cause may be found; but I have never been able to discover any, except in one instance; where it came on after a discharge from the thigh had been suppressed. A scrofulous sore had continued in the thigh for some time; and when this healed up, St. Vitus's dance began. Whether it was accidental or not, I cannot tell; but it was not cured by re-exciting the discharge, but by iron; and that with the greatest rapidity.

*Proximate Cause.*—The proximate cause, I have no doubt, is seated in the head, as well as the spinal marrow; for the very highest nerves are affected. The eyes roll; the very highest muscle of the body (the “corrugator supercilii”) is affected; the countenance is fatuous; and the mind is frequently a little impaired. Now and then we have constipation, and now and then headache and throbbing; but these form only a very small proportion of the cases.

*Treatment.*—With regard to treatment, if there is drowsiness, headache, or heat of the head, we ought to purge the patient well, take away blood either by the arm or by leeches, and treat it as a case of congestion, or an inflammatory state of the head. It is a much shorter mode to apply leeches to the head, and take away blood from the arm, than to go on with purging. Purging is good; but it is a roundabout way of affecting the head; and if there be much congestion of that organ, the best way is to take blood from it directly. Sydenham's practice was to take away blood from the arm, and purge; but what his success was, I do not know. It was rather a violent practice; and I am quite sure that, in a great number of instances, neither bleeding nor purging is required; but had those measures been practised in the case where apoplexy supervened,<sup>a</sup> the patient would probably have lost her St. Vitus's dance, and not have become apoplectic. If there be costiveness, it is our duty to remove it; if there be pain of the abdomen on pressure, besides emptying the bowels, we ought to try the common remedies of inflammation. There can be no doubt, that purgatives will sometimes cure the disease; sometimes by relieving a loaded state of the alimentary canal; and, in other cases, by circuitously emptying the head. But purgatives very often fail;—as I have repeatedly found. Children are continually brought to us after they have been well purged; and yet they are none the better for it.<sup>b</sup> An inflammatory or congested state of the head, is by no means more necessary to this disease, than it is to hydrophobia or tetanus; but it is

<sup>a</sup> See Page 623.

<sup>b</sup> Very free purging is generally recommended. Dr. Hamilton brought away, in a few days, feces amounting in weight to that of the whole body. But such treatment will not do in London; where tonics must be used. Antispasmodics may be given, and blisters applied to the spine.—*Dr. Fletcher.*

always right to look out for congestion, and an inflammatory state, and to remedy them if found.

*Tonics: Sulphate of Zinc.*—My reason for maintaining that the disease is not essentially inflammatory, and that, more frequently than otherwise, it is a mere morbid irritability, is this;—that tonics are the best remedies. Sulphate of zinc will cure a very large number of cases; and it may be given to a very considerable quantity. We may begin with a grain, in the form of a pill; but we must not exhibit it on an empty stomach, but after meals; and, in many cases, we may increase it to six, seven, or eight grains. I have given to adults from twenty to twenty-five grains, three or four times a day; but children will bear six, seven, or eight grains, three or four times a day, without nausea. This is not a newly-discovered fact. It was mentioned, long ago, that these doses may be given in epilepsy, without nauseating. The circumstance is ascribed, by Dr. Good, to the insensibility of the stomach in epilepsy;<sup>a</sup> but there is no reason for supposing that to be the cause; for it is now proved that persons in health, with no insensibility of stomach, will take it in these quantities, if we begin with a grain, and gradually increase it every day. I have repeatedly given it in this quantity, and seen others do the same.

*Copper; Silver.*—The sulphate, and other preparations of copper, will cure the disease; and so also will the nitrate of silver; but the latter is an objectionable remedy, on account of its producing a discoloration of the skin.

*Sesquioxide of Iron.*—The sesquioxide of iron<sup>b</sup> has, undoubtedly, very great power over the disease. I have had (I should suppose) forty cases in succession, all cured by this remedy. Perseverance is sometimes required; but I never had a case occurring in a child, where it was fully given, that the patient was not cured; though I have never cured a case in adults, where the disease was quite local,—situated in the head or arm. When cases occur in children, they generally become better, and the disease gradually ceases. I have not yet met with a single failure. In one, after it had been cured, the child had fever; and during the excitement of fever it returned. The child was brought to me again; and the disease ultimately disappeared. In general, the affection disappears when the remedy has been given about six weeks or two months; but I have had some obstinate cases, when it was necessary to continue it twelve weeks. I believe that a large dose will sometimes cure it, where a small one fails; but I should not give a large dose, where a small one would do; but if that would not answer, rather than give it up, I would double the quantity. Children generally like it; and, after a time, they ask for it; because I exhibit it in double its weight of treacle. Generally there is no necessity to give purgatives. I have seen headache, drowsiness, and giddiness disappear, under the use of this remedy;—an occurrence which would not, *à priori*, be expected; but if there be much heaviness of the head, I should employ leeches instead of giving this remedy;—at least at first. Some have an idea, that if we purge the patient well first, and then give the remedy, it answers better; but I have not seen that to be the case. I tried the sulphate of iron only once; and in that case the disease gave way;—the child was of a plethoric habit. It is right to continue the iron, for some time after the disease is cured; for, if we do not, the disease is very likely to return.

The oil of turpentine has sometimes been used with success; and some say colicum. Electricity along the spine, the cold bath, the shower bath, hot and cold baths in succession, and musk, will undoubtedly do good, and will now and then cure the disease; but I have tried most of them, and never found any thing so useful as the sesquioxide of iron.

<sup>a</sup> Such has been the state of exhausted irritability produced by this disease, in some instances, that the patient would bear almost any quantity.—“*Study of Medicine*,” Class 4; Order 4; Genus 7; Species 3.

<sup>b</sup> Dr. Elliotson first directed the attention of the profession to the efficacy of this remedy in the treatment of chorea, in a paper which was published in the Thirteenth Volume of the “*Medico-Chirurgical Transactions*,” Page 232; where the details of eight successful cases are given.

## SECTION III.—LEAPING AGUE.

*History.*—The form above described,<sup>a</sup> is that in which the disease usually occurs; but, now and then, persons have it in another form;—so that they dance or leap; and then it is called “leaping ague.” Perhaps it is called “ague” from not being constant, but coming on in paroxysms. This form of the disease has been very frequent in the northern parts of Scotland;<sup>b</sup> and also in Germany, and some other places. In this form of the affection, persons will sometimes run, with extraordinary facility, over dangerous places. If they have a place fixed in their imagination, they will dart forward towards it; and on arriving at it, they will drop down exhausted. Horstius states, that certain women in Germany were affected with restlessness of body, and disorder of mind; and went annually to the chapel of St. Vitus, near Ulm; where they danced, night and day, till they dropped down exhausted. They then remained well till the following May; when the affection returned, and they went through the same ceremony. It is from this circumstance that the common form of the disease is called “St. Vitus’s dance.”<sup>a</sup> The French call it “the dance of *St. Guy*,” but, not being a Catholic, I do not know who St. Guy was. Sometimes it is said, that a roll on the drum gives persons this tendency to dance; and that it is assuaged by music;—just like fits of dancing in chorea. Some do not believe that the beating of the roll has much power; but that the effect results from the motions of the body, arising from the excited state of the feelings; just like the other form of the disease which I have mentioned.<sup>a</sup>

*Symptoms.*—In this extraordinary form of the disease, some will climb in a very singular manner; others will have fits of rolling; others, fits of leaping; others will whirl round; others will tumble regularly; and others will spring and dart forwards, in any direction, to a given spot. Paroxysms of this kind will sometimes come on daily, or even oftener; and sometimes not so often. Occasionally they have been observed to be periodical to the minute; and, as in common chorea, this affection is somewhat under the will. It is a strong desire for motion, and a pleasure in yielding to it; but a strong effort will produce a little diminution of the motion. A curious case of this kind (occurring in a woman), is given by Dr. Watts, of Glasgow, in the Fifth Volume of the “*Medico-Chirurgical Transactions*.”<sup>c</sup> In this woman, there were various movements at different times; and the doctor states, that he witnessed them himself. He says that she would roll over, fifty or sixty times in a minute; and would be sometimes seized with tetanic rigidity; but that she was conscious of her own existence during these fits. In the Seventh Volume of the same “*Transactions*,”<sup>d</sup> a case is mentioned by Mr. Kinder Wood; and which, likewise, occurred in a female. She had violent fits of dancing; and it was observed by some one, that (when dancing) she struck the table, and every thing that came in her way, in regular time; and that she danced in very good time. A drum was procured, and a man beat it to the time in which she danced; and she immediately turned towards it, and danced up to it. It was not known that she had ever danced before; but she now danced in regular time, and very gracefully;—showing an infinite variety of steps. Beating the drum suddenly in a roll, or a little out of time, always stopped her; and by perseverance in this plan, whenever she began to dance, she was cured. This repeated interruption at last broke the chain. She was sensible during the paroxysm; and between the paroxysms she nursed her child, and attended to her household affairs, and had a great wish for her recovery. All the account she could give of it was, that she had a tune in her mind, which irresistibly compelled her to dance. Occasionally there are these motions, without any musical ideas whatever; and occasionally patients have involuntary musical ideas;—causing them to hum a tune, without any motion taking place in accordance with it.

<sup>a</sup> See Page 622.<sup>c</sup> Page 1.<sup>b</sup> Particularly Forfarshire.<sup>d</sup> Page 237.

*Attributed to Witchcraft.*—When these cases occurred formerly, they were ascribed to witchcraft. A case of this description occurred in Renfrewshire in Scotland, in 1696; and the ministers watched the patient in turn. A commission was appointed by government, to examine into the business, and was signed by eleven privy councillors; and it was declared that she was bewitched. A warrant was granted, and several persons were apprehended, and afterwards brought to trial, for having bewitched her. After six hours' deliberation of the jury, three men and four women were found guilty; and were condemned to be burnt for having caused the disease; and the sentence was actually executed at Paisley, on the tenth of June, 1697. A case exactly like this, but not ascribed to witchcraft, is recorded in the "Edinburgh Medical Journal" for 1829. Bishop Jewel, in a sermon preached before Queen Elizabeth, said:—"It may please your Grace to understand, that this kind of people, (I meane witches and sorcerers,) within these last few years, are marvellously increased within this your Grace's realme. These eies have seene most evident and manifest marks of their wickedness. Your Grace's subjects pine away, even unto the death;—their colour fadeth; their flesh rotteth; their speech is benumbed; their senses are bereft. Wherefore your poore subjects' most humble petition unto your Highnesse is, that the lawes touching such malefactors may be put in due execution. For the dole of them is great; their doings horrible; their malice intollerable; the examples most miserable. And I pray God they never practise further than upon the subject." In the next session a bill was brought into parliament for making witchcraft felony; and those who know any thing of history, must be aware that thousands of victims were sacrificed. All singular nervous diseases, and many other calamities, were ascribed especially to witchcraft.

There is an account, in the "Ephemerides," of a girl who sprang up while in a horizontal posture, and came down again. The mother consulted a medical man; and he told her he could do nothing for her. He attributed it to the devil; and directed her to go to a clergyman. Voltaire says, that the greatest enemies the devil has are the doctors;—that it is the doctors who do away with one half of his dominions;—so much was formerly ascribed to him, and to those connected with him.

*Pathology.*—One has some clue, I think, to these motions, in the experiments of Magendie. He says, that if the white matter of both "corpora striata" be cut, the animal darts forward; or, if this be prevented, it still retains a progressive attitude. He says, that if the "crura cerebelli" or the "pons varolii" be cut, from before backwards, an animal rolls over sixty times in a minute. That I have witnessed myself. He likewise states, that if we cut vertically from the "crura cerebelli," through the arch of the fourth ventricle, it has the same effect; and the motion is more rapid, as the section is nearer that point. If incisions have this effect, we may easily conceive that a certain local affection may have a similar effect in being the cause of this disease. Cases are recorded of persons, who had a mere propensity to rush forward or backwards.\*

*Causes.*—Some of these affections are clearly the result of mere excitement of mind;—some violent passion. Sometimes they raise from witnessing other people under the disease: but occasionally they appear to arise from certain causes within the nervous system itself, independently of all external circumstances. When they arise merely from external circumstances, a large number of cases occur together; and in Germany they have been epidemic;—that is to say, they have affected a large number of people at a time.

*Treatment.*—When these cases are sporadic, we should naturally be inclined to

\* Sometimes there is an uncontrollable propensity to running, which appears to be from both "corpora striata" being affected. If only one of these bodies be engaged, a rotary motion is produced, as is often seen in dogs labouring under inflammation of the brain. When the upper limbs are convulsed, it is probably from an affection of the optic thalami.  
—Dr. Fletcher.

treat them like St. Vitus's dance;<sup>a</sup> and I have no doubt they would be cured in the same way. When they are epidemic, we ought to have recourse to mental remedies. We should separate the patients; and not allow one to be excited by seeing another. Strong corporeal measures can be of little use, and medicine must be out of the question; but when these cases occur without any external excitement, from simple irritation (although I never had such a case), I have no doubt that the cold-bath, oil of turpentine, and those things which cure St. Vitus's dance,<sup>b</sup> will also cure this affection.

## CHAPTER XII.

### TETANUS.

#### SECTION I.—SYMPTOMS AND PROGRESS.

*Definition.*—The name of the disease I am now about to consider, (tetanus,) is derived from the Greek word *τενω*, to stretch;—in consequence of the great stretching and spasm that exist in this disease. There is a constant rigidity and contraction of certain voluntary muscles, not alternating with relaxation; yet there is a much more violent contraction at one moment than at another. There is a *constant* contraction of the muscles affected; but they are not constantly contracted to the *same extent*. There are *paroxysms* of spasm, as well as *constant* spasms; and the paroxysms are more frequent, and also more violent, in some cases, and at some periods in the same case, than in others. Synchronous with these violent spasms, there is violent pain; and the muscles so affected by spasm, are always very hard. There is one extraordinary case mentioned by Sir Gilbert Blane, of a man in the navy who had tetanus; and, instead of experiencing a violent agony from the spasm, he had nothing but pleasurable sensations. It is considered a very extraordinary case; and the disease could not be trifling, for he died on the fourth day. I do not believe that Sir Gilbert Blane saw the patient himself; but he relates the case on the authority of a surgeon in the navy.

*Varieties.*—These painful spasms chiefly affect the muscles of the lower jaw, of the neck, and of the trunk. When they affect the jaw, that variety of the disease is called “trismus.” When the spasms are such that the body is drawn backwards and arched (the convexity of the arch being *forwards*, and the whole body drawn *backwards*), this state is called “opisthotonos;” when the body, on the other hand, is drawn *forwards*, it is denominated “emprosthotonos;”<sup>c</sup> and if the body be drawn to one side, then it is termed “pleurosthotonos.”<sup>d</sup> Trismus and opisthotonos are the most common. Sometimes the spasms affect the muscles of the extremities; but in general they do not; and the fingers are often flexible to the very last; while the trunk, the neck, and the jaw, are in a state of the utmost rigidity.

[Some writers divide tetanus into “general,”—when the whole muscular system is affected; and “local,”—when there is rigidity of one or several muscles, as in cramp, priapism, &c. Tetanus has also been distinguished, as regards its duration, into “acute” and “chronic;” though the limits where the one terminates, and the other begins, have not been fixed. Two varieties have also been established,—“idiopathic” and “symptomatic;”—the former arising from causes acting directly on the nervous system, the latter from the irritation in other organs

<sup>a</sup> See Page 624.

<sup>b</sup> See Pages 624 to 625.

<sup>c</sup> From *εμπροσθεν*, *forwards*; and *τενω*, to draw.

<sup>d</sup> From *πλευρῶς*, *the side*; and *τενω*, to draw.

being propagated indirectly to the nervous centres. Thus tetanus following wounds (termed "traumatic") belongs to the latter variety. It has also been divided into the "continued" and "periodic;" in the former the rigidity does not disappear entirely, but the symptoms sometimes suddenly increase; in the latter there are complete intervals, or interruptions of the tetanic rigidity;—the symptoms, in some cases, recurring at stated or fixed periods. The "continued" forms are always acute or subacute; the "periodic" always chronic. Dance has recorded four cases of the latter variety.<sup>a</sup> Hufeland<sup>b</sup> has also seen a case that for years returned at regular periods, which lasted eight hours.<sup>c</sup>]

*Symptoms.*—The muscles of the face are affected; and the consequence of this is, that the brow becomes very much corrugated. The "corrugator superciliar" of each side suffers in the spasm, and the other muscles of the face are affected; so that the angles of the mouth are drawn up into an agonizing expression; and the patient is compelled to a wretched grin; which is, no doubt, greatly increased by the agony which the patient suffers. The nose is drawn up; and the eyes are fixed, staring, and startling. The tongue is continually protruded, during the patient's sleep, if the jaw be not completely closed; and when it is protruded, spasms continually affect the masseter and temporalis muscles; so that the jaws snap, and the tongue is caught and wounded. The diaphragm, too, is greatly affected; on which account there is a catching of the breath, and violent pain at the end of the sternum. At any rate, these spasms produce a catching of the breath; and, I presume, the pain at the end of the sternum arises from the same source. From the spasmodic state of the abdominal muscles, the abdomen is extremely hard and swollen;—in fact, as hard as a board. The recti muscles are seen prominent in all their departments. The least motion, or the least attempt at motion, frequently excites these violent spasms; so that if the patient attempt to move in bed, violent spasms follow. The "sphincter ani" sometimes seems to be violently contracted; so that a clyster cannot be given. This, however, is not invariably the case. From this violent muscular action, there is great heat and great sweating. Dr. Fribo, of Geneva, found the temperature of the body 110 degrees in the axilla. In this disease the pulse is quick, exactly in proportion to the severity of the affection. It is much quicker at the moment the spasm is aggravated, than at any other time. The first symptoms of the disease generally show themselves about the neck and tongue. Usually the first symptom of which the patient complains, is a difficulty in mastication and deglutition; and then there is generally a slight stiffness about the back of the neck.<sup>d</sup>

*Duration.*—The course of the disease is various. Sometimes it proceeds very rapidly, and sometimes very slowly; so that it may last only one day;—destroying life in twenty-four hours; or it may last many weeks. It frequently kills before the fourth day; and when it does terminate fatally, it generally proves so before the ninth day. As to duration, Dr. Parry mentions that a horse attacked with this disease, did not die before the eighteenth day of seizure. When a patient dies, it is either during the violence of the paroxysms, or from being completely exhausted.<sup>e</sup> The mind is usually quite unaffected, except sometimes towards the last. It is common to almost all diseases, for the mind to become slightly affected. The bowels, in this affection, are always costive.<sup>f</sup> If the patient recover, it is generally

<sup>a</sup> "Dictionnaire de Médecine et Chirurgie Pratique."

<sup>b</sup> "Manuel de Médecine Pratique; par Jourdan;" Page 234.

<sup>c</sup> "Library of Medicine;" Volume 2; Page 231.

<sup>d</sup> Tetanus begins in the jaw;—the motific branch of the third division ("inferior maxillary") of the fifth pair of nerves ("trigemini") being first affected. There is "risus sardonicus;" the eyes are half open; the disease extends to the neck; and then to the trunk. In the extremities, the *flexors* are first attacked, and then the *extensors*;—as in all cases of spasmodic disease; whereas, in paralytic diseases, (as in the affection of the wrist from "painters' colic,") the *extensors* are first attacked. Thus, *added and diminished* nervous power affects different sets of muscles first.—*Dr. Fletcher.*

<sup>e</sup> Death generally results from asphyxia, nervous apoplexy, or a general convulsion.—*Dr. Fletcher.*

<sup>f</sup> This costive state has been attributed to spasm of the anus; to spasms extending from the voluntary muscles to those of the intestines; to the opium administered; and to a spasm

by a very gradual cessation of the symptoms; and the disease lasts from two to four weeks, and sometimes six or eight. It is from these long-continued cases, that recovery usually takes place. It now and then, of course, remits; and then again it is aggravated.

*Morbid Appearances.*—After death, in most cases, nothing wrong is found; and therefore the morbid appearances which are sometimes found, are not *essential*, but *incidental*. Occasionally, we find inflammation of the spinal marrow; but sometimes (and I cannot but fancy I have seen instances of it myself) the congestion so common about the spinal marrow, when the body lies long, has been mistaken for inflammation of the spinal canal. In the ordinary position in which dead bodies lie, the blood gravitates towards the spine; and if the body be not soon examined, and the weather be hot, we may expect great redness of the spinal membrane from the blood effused there; and yet there may be no inflammation. When we consider that, in the majority of cases, there are no signs of inflammation, we cannot but conclude that, although inflammation of the spinal marrow may sometimes give rise to tetanus, yet the disease is not necessarily the result of inflammation of that kind.

*State of the Nerves.*—[In traumatic tetanus, the nerves in the neighbourhood of the wound have often been found more or less injured, or to have undergone morbid alterations. In certain cases they have been contused, lacerated, partially divided, irritated by spicula of bone, or other foreign substances, included in ligatures placed on arteries, or participating in the inflammation of the surrounding textures. In the latter case, the appearances have differed according as the inflammatory action was acute or chronic;—injection (more or less intense), and softening being evidence of the former; and thickening, induration, and discoloration of the latter. Lobstein<sup>a</sup> and Andral<sup>b</sup> have observed signs of inflammation or redness in the semilunar ganglion; and Swan<sup>c</sup> has often seen the ganglia of the sympathetic system in general considerably injected;—an appearance which has been occasionally observed by other authors.

*Other Morbid Lesions.*—In an individual who died of opisthotonos, Dupuytren found the muscles gorged with blood, and lacerated. Larrey and Curling give cases where one of the “recti abdominis” muscles was torn across. The pharynx and œsophagus were often seen by Larrey contracted; and their mucous membranes red, inflamed, and covered with a viscid reddish mucus. The large papillæ at the root of the tongue, have occasionally been found thickened; and the mucous lining of the larynx, injected and covered with frothy mucus. Andral gives a case, where unequivocal marks of gastritis were discovered; and, in four cases, M<sup>r</sup> Arthur found inflammation of the alimentary canal, with a peculiar yellow matter covering the mucous membrane of the stomach and œsophagus; which, in one case, effervesced on being exposed to the external air. Worms have been discovered in the intestinal canal by Sauvages, Laurent, Larrey, O’Beirne, and others. The last writer states, that distension of the cæcum and colon is a constant pathological appearance. In a case related by Mr. Howship, the heart was much indurated, and presented considerable resistance to the knife.<sup>d</sup>]

## SECTION II.—CAUSES.

*Predisposing Causes.*—The predisposing causes of the disease, are, in the first place, hot climates and hot seasons. The disease is far more common in hot climates, than in temperate ones; and more common in hot seasons, than in those

of the extremities of the intestinal arteries. But none of these causes are satisfactory.—*Dr. Fletcher.*

<sup>a</sup> “De Nervi Sympathetici;” Page 152.

which are mild. It appears that, in hot climates and hot seasons, it prevails most from the want of ventilation, the want of good food, the want of comfort, and the want of attention to the bowels. On this account it is much less frequent in the army and navy now, than formerly. Dr. Lind says that, in the West Indies, at the end of the former war, five cases of amputation out of six proved fatal, through the occurrence of tetanus;<sup>a</sup> but Dr. Dickson, physician to the Fleet, (in an article published in the Seventh Volume of the "Medico-Chirurgical Transactions," Page 448,) says that there were not under his care, in the West Indies, above six cases of tetanus arising from amputation, for upwards of seven years. He ascribes this fact to the improvement in the treatment of sailors, both in sickness and in health; and to their having more comforts, and being less exposed to noxious causes. Dr. M'Arthur, of the Naval Hospital at Barbadoes, says<sup>b</sup> that only four cases occurred there, in the course of nearly four years; and yet there were many wounds, and many amputations during the war.<sup>c</sup> This is another instance of the effect of external circumstances upon the existence and severity of various diseases. Fever prevails most among those who manifest a want of cleanliness; and so, it is said, do cholera and typhus. But diseases very dissimilar to each other, will be pre-disposed to by a want of comfort; for the more the comfort of the body is attended to, the less is the influence of all noxious agents, and noxious circumstances.

Males are thought to be more disposed to the disease than females; but this is not proved; for males are more exposed than females to the exciting causes of the complaint. It is also thought, that the strong and muscular are more liable to it than the weak; but whether that is really the case I do not know; for I have seen a great number of instances of tetanus, in persons of all sorts of constitutions, both strong and weak. It is supposed to occur particularly in young adults; but it occurs also, in the West Indies, in infants. Children there (though now less frequently than formerly) die of locked jaw; so that one variety of the disease is called "*trismus nascentium*."<sup>d</sup>

*Exciting Causes.*—Among the exciting causes of the disease, is to be mentioned sudden refrigeration, when the body is hot; but the most common is a wound; and (what is singular) it is wounds of the hands or feet, that most frequently cause it, and, among wounds of the hands and feet, it is wounds of the fingers and toes, that most frequently cause it; and among wounds of the fingers and toes, it is most frequently wounds of the thumbs and great toes, that produce it.

*Depends on the Kind of Wound.*—Every wound has not an equal tendency to produce tetanus; for contused wounds much more frequently occasion it than any others. A wound will sometimes not produce the disease, till the person is suddenly exposed to cold; and then he will have it immediately. This is a similar occurrence to that which takes place in ague; namely, that a person may be exposed to the causes of ague, and yet the disease will not appear, until he is exposed to cold and wet. The cause then becomes efficient. So a wound will frequently not produce tetanus, till another cause of the disease takes place;—sudden refrigeration; and then the affection makes its appearance. The reverse of this, however, sometimes happens. The person is exposed to wet; but the disease will not show itself, until a wound takes place.

*The State of the Wound.*—It occurs in all states of the wound;—in healthy and unhealthy wounds. Sometimes it appears when the wound is nearly healed; and sometimes when it is perfectly healed. It occurs, too, whether the wound be large or small. I had a case of tetanus, as severe as any I ever saw, where there had been merely a contusion of the thumb. There was no pain,—no irritation. The nail was separated and loose; but under it, all was dry. No secretion was going on, and there was no irritation to be found; and yet the contusion of the thumb

<sup>b</sup> In a letter dated February 22, 1808; and published in the Seventh Volume of the "Medico-Chirurgical Transactions;" Page 466.

<sup>c</sup> "Medico-Chirurgical Transactions;" Volume 7; Page 476.

<sup>d</sup> See Page 632.

produced the disease. There is a case mentioned in the "Transactions of the London Medical Society,"<sup>a</sup> in which the disease occurred after a burn; at the time when there was merely a dry scab on the leg, and no inflammation around it; nay, the disease has sometimes declined and ceased, while the wound every day grew worse and worse. I had a case of tetanus from compound dislocation of the great toe; in which the disease declined, and ceased, while the pain continued in the foot. Inflammation and suppuration went on, accompanied by great suffering; and yet the disease was declining all the time. *Trismus nascentium*,—the "lock-jaw" of newborn infants,<sup>b</sup> has been ascribed to the state of the navel,—to the condition of the parts connected with the umbilical cord;<sup>c</sup> but it appears, that it is greatly disposed to by the unhealthiness of the circumstances in which the children of the West Indies are placed.

*Period at which it may Occur.*—Sir James M'Grigor says that it appeared, from his immense experience in the Peninsula (as army-surgeon), that a person wounded was safe, as it regarded tetanus, if the disease had not begun by the twenty-second day after the infliction of the wound. But Sir Gilbert Blane (who had, if not equal, yet very great experience in the navy, many years ago) says, that he has seen the disease occur at all periods of a wound, between the second day and the end of the fourth week. Sir James M'Grigor found the twenty-second day the limit; but Sir Gilbert Blane has seen it up to the end of the fourth week, from the time of the infliction of the wound; so that a person is not safe, according to him, even if he have passed the twenty-second day. Dr. Parry mentions seeing a horse seized with the disease on the thirtieth day. I may mention, that tetanus is not only common in horses; but that lambs are affected with it, if their ears be bored with a red-hot iron, to check the rot. It has been said to arise, frequently, from worms in the intestines.

*Pathology.*—All I can venture to say as to the nature of the affection is, that it is a peculiar state of that part of the brain or spinal marrow, which is immediately connected with the nerves of the voluntary muscles. What that state is, I cannot pretend to define; but that is the situation of the proximate cause, I have no doubt. The mind is entirely unaffected in the disease; and so is sensibility. It appears to be an affection of the voluntary muscles, through the medium of the voluntary nerves.

### SECTION III.—DIAGNOSIS AND PROGNOSIS.

*Diagnosis.*—In almost every case, we observe that the tongue is bitten. Before the mouth is completely closed, and the patient falls asleep, the tongue is protruded by the spasms. The spasms affect the entire set of muscles; and therefore we may expect, in most cases, a biting of the tongue. A second symptom, very characteristic of the disease, is the pain at the "*scrobiculus cordis*." It is a pain not increased by pressure; but a sudden, violent, sharp, stabbing pain. It may be more or less constant; but at periods it is exceedingly severe. There is also a peculiar swelling and rigidity of the muscles;—a state which is spasmodic, but constant, not convulsive. It is what they call "*a tonic spasm*;"—not a spasm alternating with relaxation ("*clonic*"). Then, again, the body is drawn into a peculiar posture;—*opisthotonos*, *emprosthotonos*, or *pleurosthotonos*;<sup>d</sup> and in *trismus* the jaw is closed, or nearly so, without any inflammation around, and without any organic disease to account for it.

*From Hydrophobia.*—There is no terror in this disease;—no excitement of the mind;—no morbid corporeal sensibility. We shall see, that in hydrophobia there is excessive terror,—excessive excitement of mind,—a great sensibility to external

<sup>a</sup> Volume 6; Page 77.

<sup>b</sup> See Page 631.

<sup>c</sup> It has also been attributed to cold, and to retention of the meconium. Hide-bound children often die of this disease.—*Dr. Fletcher*.

<sup>d</sup> See Page 632.

sensation; so that neither noise, nor light, nor a sudden draught on the body, can be borne;<sup>a</sup> but in tetanus, although the patient is miserable enough from the agony, yet there is no *mental* distress,—no terror of mind; neither is the body extraordinarily sensible to external applications.

*From Rheumatism.*—Rheumatism, when it occurs, chiefly takes place in the joints, and not in the bellies of muscles; or if it do, the joints are affected likewise; and there is no spasm, but a difficulty of motion, and great pain when the patient moves; and many joints are frequently affected at the same time. As to the distinction between a locked jaw and rheumatism, it may be observed that, in the latter, other joints are most probably affected. The jaw may be stiff; but there is violent pain flying from one part to another; and the patient is not subject to a snapping of the tongue. In rheumatism, too, there is generally tenderness in some part of the jaw; and generally there is a great deal of heat, as well as constant pain.

*From Hysteria.*—Tetanus, more especially trismus, is very frequently hysterical; but this occurs, in ninety-nine cases out of a hundred, in females; and there are other hysterical symptoms;—such as “globus hystericus,” great flatulency, and irregular convulsions. If hysteria be present, and trismus (or any other form of tetanus occurs), we may take it for granted that it is an hysterical affection altogether.

*Occurring during Ague.*—I mentioned, when speaking of ague, that tetanus sometimes occurs during that affection, particularly during the cold stage;<sup>b</sup> and I presume it is not dangerous. The utmost that I have observed, is a constant tonic spasm of the arm;—that is to say, I had two patients under my care, whose hands were clenched during the cold stage.

*Narcotics.*—Narcotics sometimes have occasioned this disease. A tobacco-clyster will sometimes occasion it; but it is strychnine, more particularly, that has this effect. In these cases, if we knew that poison had been swallowed, we should ascribe it to that; but if a narcotic had been taken, I presume we should, in most cases, find some other symptom present in addition to the tetanus.

*Prognosis.*—The prognosis, in this disease, is always bad; unless it be a sympathetic affection. If hysteria be present, or if the disease have been produced by a narcotic, the prognosis will not be so unfavourable; for the narcotic will frequently be got the better of. In such circumstances, the prognosis is very various. If, however, the disease be what is called “traumatic” (arising from a wound),<sup>c</sup> or if it be occasioned by worms in the intestines, few persons recover from it. But every description of tetanus, whatever be the cause from which it occurs, admits of recovery. Dr. Parry says, on the subject of prognosis, that if the pulse be not above 100, or 110, up to the fourth or fifth day, patients almost always recover; but that if the pulse be quicker early, the disease almost always proves fatal; and that there have been but very few recoveries, when the pulse has been 100 the first day. There is less danger in proportion to the length of time which the disease lasts. If we are called to a case which has lasted some time, our prognosis may be favourable.

#### SECTION IV.—TREATMENT.

*Bleeding.*—If the wound be inflamed, or if there be any internal inflammation, or if there be fulness of the system, undoubtedly we should bleed. It is said, that enteritis sometimes exists in the disease; but I have not seen it. We are not to imagine, that because the blood flows freely, the patient must be benefited by blood-letting; because, while there is such violent action of the voluntary muscles, the effect must be the same as that which we every day procure in common venesection, by making a person contract his hands, so that the muscles may press on the internal veins. When all the muscles are in a state of violent spasm, as in

<sup>a</sup> See Page 633.

<sup>b</sup> See Page 235.

<sup>c</sup> See Pages 631 and 632.

tetanus, we may expect that the circulation will be irregular;—that a great quantity of blood will be forced to the superficial veins; and consequently that the blood will flow freely; and bleeding is not at all useful, unless the wound is inflamed, or there is some decided internal inflammation, or the patient is clearly in a state of plethora.

*Purgatives.*—Purgatives are often useful; especially in the case of children, when they are labouring under “trismus nascentium.”<sup>a</sup> I believe there is benefit, in general, from clearing out the intestines well; and some cases have done well under the use of purgatives in adults, where there has been some irritation in the intestines (worms, or something else) producing the disease. In general, both bleeding and purging do good; but, at any rate, it is always right to clear out the bowels. Among purgatives, I think the oil of turpentine is one of the best. It clears the bowels thoroughly; and, in cases of *hysterical* locked-jaw, I have seen it produce an instantaneous effect. Cases are on record (and I have seen several instances myself) where, in trismus of a hysterical nature, the jaw opened the moment an injection of oil of turpentine was passed up; and in other cases I have seen it open a few hours afterwards. If two or three ounces of this medicine cannot be got down by the mouth, (and it is of no use to give less,) we may exhibit three ounces (diffused in gruel) by the rectum. Should this not answer, a large dose of calomel should be given. If the pills cannot be swallowed, we may place the calomel in the mouth. Mercury to ptyalism has been said by some to do good.

*Narcotics.*—Opium and other narcotics have been tried in this disease; but the agency of all remedies is greatly resisted, and therefore very large doses of narcotics are borne. Half a pint of laudanum has been given without doing injury. Dr. Morrison, a gentleman who has practised in the West Indies, says he has been in the habit of treating these cases there; and that it is very common to give one hundred drops of laudanum, as a starting dose; and to follow it up every two hours;—increasing each dose by one-third of the preceding one. He also allows the patient wine and ardent spirits; employs the warm bath; and exhibits mercury to ptyalism;—paying due regard to the bowels; and he states, that the result of this practice was the recovery of more than one-half of his cases, although the tetanus was of a traumatic character. However, we have all seen opium exhibited in a large quantity, even to stupefaction, without doing any good. Prussic acid appears to have failed entirely in this disease. It has been frequently and freely given; but it has failed; and so likewise has belladonna. Some cases appear to have done well, by means of an injection of tobacco. It appears to have relaxed the spasm, and cured the disease. Dr. Latham (Senior) praises opium and ipecacuanha; which, he says, produced copious sweating. He states, that the success from a combination of these remedies, has been very great.

*Warm and Cold Bath.*—The warm bath appears to have done no good, and sometimes to have been really injurious, while, on the other hand, the cold bath and cold affusion have relaxed the spasm; but have sometimes killed the patient at once, as if he had been shot. I presume, if the cold bath or cold affusion be employed, it ought to be at the moment that the violent spasm is on. I know of an instance where a patient was taken out of bed, in a hospital;<sup>b</sup> put on a chair; placed in a tub in the middle of the ward; and a pail or two of water dashed upon him. He fell down dead, as if he were shot;—never spoke again; and all the other patients were very much shocked. Yet there are cases in which that very remedy appears to have cured the disease. There are many cases of the latter description on record; so that the practice, I should imagine, is justifiable; though I have no experience of it. The error, if there be error, consists in the cold water not being thrown on the patient when he is at the very worst. The moment we find a catching of the breath, from violent spasm, I would dash on the water; for I think its agency, in that case, would not be sufficiently severe to produce danger. But Sir James M'Grigor says, from the result of very extensive trials of the cold bath, in the Peninsular war, that it was worse than useless.<sup>c</sup>

<sup>a</sup> See Pages 631 and 632.

<sup>c</sup> See Note (b) to Page 635.

<sup>b</sup> St. Thomas.

*Blisters.*—Blistering along the spine *may* be serviceable; but it is often found useless, and is unquestionably a very cruel remedy.

*Result of Sir J. M'Grigor's Experience.*—Sir James M'Grigor says, as the result of his experience in the army, that all remedies (except one that I do not see spoken of,—iron) have been fully tried in some hundreds of cases; and that there is little or no dependence to be placed upon them. I have looked over the list he has furnished; and, upon my word, there is almost every thing mentioned that ever was used in medicine. Sir James M'Grigor says, that the mode of treatment is certainly still to be discovered;<sup>a</sup> and that, as there is no analogy to guide us, there is little hope that any remedy will ever be found out.<sup>b</sup> Recovery has taken place under all means of treatment; and recovery has taken place under *no* means.

*Iron.*—It struck me, from seeing the benefit that iron produced in St. Vitus's dance, that as this is a similar disease, although infinitely more severe, (characterized, not by a *slight catching* of the muscles, but by *violent spasm*,) that iron might still have the same effect. I saw clearly that, in the exhibition of narcotics, we were on a wrong scent; because we may give opium till the patient is stupid, and yet the disease generally proves fatal;—at least, in this country. In these circumstances, I determined that, if ever a case came under my care, I would give iron a fair trial.

*Case.*—At length a case did occur; this remedy was fairly exhibited; and the man recovered. The case was one of traumatic tetanus, arising from compound dislocation of the great toe. It was a well-characterized case; and several persons went to look at it. The sesquioxide of iron was made into an electuary, with double its weight of treacle; and each dose was mixed with a quantity of beef-tea, and stirred up well, as it was going into the patient's mouth. It was given every two hours. He took it *ad libitum*; and recovered.

*Case.*—It was not long before I had another case. It arose from a contusion of the thumb; and was the case in which I stated the nail was separated.<sup>c</sup> This was as severe a case, not terminating fatally, as ever I saw. It was a *frightful* case; and, in this patient, the sesquioxide of iron was administered in still greater quantity. There was no limit fixed; and it was found that he had taken two pounds in a day! His bowels were carefully attended to; and an injection was given three times a day. The iron came away in large lumps;—very similar to the balls of *scæces* which come from a horse; and they were perfectly red. However, the man in two days was decidedly better; and he repeatedly came, after his recovery, to thank me for what had been done for him.

*Case.*—A third case came under my care, some years ago: and occurred in a boy who had had a chilblain on his heel, or a little higher up. He was brought to the Hospital,<sup>d</sup> in a most frightful state: and the disease was so violent, that I had no hope of doing him good;—fearing that he would die, before the remedy could be brought into operation upon his body. It was prescribed for him; but he died before twenty-four hours had elapsed. Iron is a medicine that will not produce an immediate effect. To produce its effect upon the system, it must be given for a few days. This patient died in a violent paroxysm. I saw him in the afternoon, about one or two o'clock; and he died early the next day;—so that it was not a case in which the remedy could exert its influence. It is not a remedial agent which produces an instantaneous effect, like bleeding. In St. Vitus's dance, it is sometimes months before it produces its effect; and so it is in the *douloureux*, and also when given as a tonic.

Whether the two first of these were cases cured by the iron, I will not pretend

<sup>d</sup> St. Thomas's.

to say; I dare not assert that they were. I employed it from the analogy of the affection to St. Vitus's dance; both cases were traumatic; and the patients did well,—not by lingering out; for in two or three days they began to mend; and were well speedily. There is a *probability*, but no *certainty*, that the disease was cured by iron. The cases, however, are interesting; as they make it an object to give iron a fair trial, in any other cases that may occur. I have had but three cases of tetanus, from the time that I determined to give this medicine a trial. In two of these it appeared to succeed; in the third there was no time for the fair exhibition of it.

I was mentioning the circumstance to a gentleman, whom I had met in consultation some few months ago, and who had practised in the West Indies; and he informed me that, in consequence of the publication of those cases in the “*Medico-Chirurgical Transactions*,”<sup>a</sup> he had used it in the West Indies; and I think he said eight cases recovered out of ten; and in the two cases which did not recover, the symptoms were so severe, and the jaw so thoroughly closed, that it was impossible to get the iron, or any thing else, down the throat.

*Constant Refrigeration.*—There is a case mentioned by Sir James McGrigor, in the sixth volume of the “*Medico-Chirurgical Transactions*,”<sup>b</sup> and also in his reports (which are very interesting) of the diseases of the army in the Peninsular war. It proceeded from a slight wound in the finger. The patient (a soldier, of course) was carried in a bullock-car after the battalion to which he belonged, in a severe state of tetanus, in the midst of pouring rain; which completely drenched him in the early part of the day;—the heat being 52 degrees; and then they ascended the highest mountain in Galicia, the snow on the summit of which was knee-deep; and there the temperature was only 30 degrees. He was exposed in this condition, from six o'clock in the morning till ten o'clock at night; and arrived at his journey's end, half starved from cold, but perfectly cured of his tetanus. Whether such a mode would succeed, if it were put into practice intentionally, I do not know. I stumbled on a similar case, published in 1827. A horse which was in a state of tetanus, happened to be in a wet park, and was drenched with rain;—precisely as was the case with this unfortunate man; and the horse also did perfectly well. Whether the depressing power of cold and wet, regularly kept up for a certain number of hours, has a tendency to cure the disease, I do not say; but I think that, in a disease of violent excitement as this is, the constant,—not *sudden*, but *constant* refrigeration (by means of a low temperature, united with moisture,) is likely to be of great service. There are at least two such cases on record; and it is surprising to find a soldier, so exposed from morning to evening, recover; and especially in so short a time as one day.

*Whirling Machine.*—For the purpose of lessening the spasms, some have proposed a whirling machine; so as to make the patient giddy, and powerless; but I do not know that it was ever attended with success.

*Amputation.*—If there be a wound, the removal of the part is perfectly useless. I had a case of tetanus, some years ago, in which an operation was proposed;—in consequence of the disease having arisen from a compound fracture of the leg. The extremity was cut off, but the patient was no better; and now it is with me, and I believe most others, an established rule not to remove the wounded part. After a long search for cases, in scores of journals and medical books, I have been able to find only one instance, where the removal of the part appeared to be attended with the removal of the disease. Instances are so rare, that (I believe) amputation of a part is never thought of at the present day.

*Division of the Nerves.*—[Whenever the symptoms appear a short time after the reception of a wound, and there can be no doubt that the wound is the exciting cause of the disease, all nervous communication between it and the spinal marrow should be cut off as soon as possible. It is a singular fact, that this practice,—which our knowledge of pathology and physiology shows to be necessary, and

likely to be successful,—has only (as far as medical records go) been performed four or five times, but in all these with perfect success. In a case related by Dr. Murray,<sup>a</sup> occasioned by a wound in the left foot, the posterior tibial nerve was divided; and although the patient could not articulate distinctly before, from the closure of the jaws, he immediately opened his mouth with an exclamation, and expressed himself as being benefited. He rapidly recovered.<sup>b]</sup>

*Protect the Tongue.*—In treating the disease, whatever remedies we employ, it is right to introduce a cork (or something of that kind) into the mouth, to save the tongue; or the latter will be dreadfully bitten. This should always be carefully attended to.

*Support the Patient, in the Chronic Form.*—When the disease runs on, and becomes chronic, it is necessary to support the patient well. By doing this, we give him a greater chance of recovery. Dr. Currie, who wrote on Cold Affusion, has given<sup>c</sup> an account of a man labouring under tetanus so chronic, as to last forty-two days; and who in this time drank one hundred and ten bottles of port (so that he got something by his tetanus); and yet not the least approach to intoxication occurred; and he recovered perfectly. Certainly one hundred and ten bottles of port, in forty-two days, was very good allowance; and, I should think, made him pass his time pleasantly. There is also, in the same paper, an account of a horse labouring under tetanus; which, during the disease, drank as much port wine as he was worth. I do not know his value; but his owner was so fond of him, that he allowed him port wine; and he recovered, after drinking as much as his original cost. In the chronic form of the disease, therefore, we ought to support the patient as well as possible; and wine is highly serviceable.

## CHAPTER XIII.

### HYDROPHOBIA.

#### SECTION I.—SYMPTOMS AND PROGRESS.

*Dysphagia.*—I now proceed to another disease, bearing a certain resemblance in some of its symptoms to tetanus, of which we have just spoken;—I mean hydrophobia (ὕδωρ, *water*; and φόβος, *to fear*);—so named because it is imagined there is a fear to plunge into, to swallow, or even to look at water. But although the disease has its name from a dread of water, yet this dread of swallowing water, as well as other things, is seen in certain common nervous and other affections. People will take an antipathy to all liquids; and sometimes, in common sore-throat, there is such a spasmodic disposition in the throat, that the attempt to swallow excites great irritation; and the recollection of it excites fear at the very sight of water; while the attempt to drink it is terrific. On the other hand, the fear of water,—the fear of swallowing, is not universal in hydrophobia. Persons sometimes swallow very well in hydrophobia, and put their hands into cold water;<sup>d</sup> dogs will swim across a stream; and some persons, it is said, drink quite well to the very last. I believe I have seen this occurrence myself.

In many cases of this disease, there is as great difficulty in swallowing *solids* as *liquids*; an instance of which is published by Dr. Marcet, in the first volume of

<sup>a</sup> "Transactions of the Medical and Physical Society of Calcutta."

<sup>b</sup> "Library of Medicine;" Volume 2; Page 242.

<sup>c</sup> In a paper published in the "Transactions of the London Medical Society."

<sup>d</sup> See Pages 638, 639, and 640.

the "Medico-Chirurgical Transactions."<sup>a</sup> Still, in this disease, it must be allowed that it is most usual for a person to have a fear of swallowing, touching, seeing, or hearing the sound of liquids. Some years ago, there was a patient in St. Thomas's Hospital, labouring under this disease; and the circumstance of one of the dressers who sat up with him making water within his hearing, threw the boy into a violent agitation. But the dread of drinking, and of touching water, is only a symptom; and there can be no doubt that even though it never happened, death would equally occur.

*Extreme Sensibility of the Surface.*—The real character of the disease, is to be taken from the circumstance of the extreme sensibility of the surface of the body, and the extreme sensibility of the nerves of deglutition and respiration; so that any attempt at swallowing, the application of cold air to the surface, the application to the surface of a drop of fluid, whether warm or cold, if made suddenly (as by sprinkling);—even the circumstance of an insect crawling on the face or hands, or the slightest agitation of the bed-clothes; any of these things will produce a catching of the breath,—a sudden inspiration;—just such as we experience when we step into a cold-bath. The diaphragm descends;—just as if cold water were thrown upon us, or the wind blew suddenly upon us. Contemporaneously with the descent of the diaphragm, there is a violent spasm about the larynx and pharynx; so that swallowing is impossible, and so likewise is breathing. The diaphragm will descend; but a spasm of the glottis occurs, and the air will not go down. The glottis will relax again, and a number of successive closures take place; and, at the same moment, from the fear of being choked, there is extreme anguish, and extreme terror.

*Intolerance of Noise and Light.*—Even noise and light will produce this. Not merely the circumstance of cold air blowing on the patient, but the mere draught occasioned by a pocket-handkerchief, or by waving the hand,—so as to cause the air to come with full force against him,—may produce this violent spasm; and not only so, but the mere reflection of a looking-glass will have the same effect. If a looking-glass be allowed to play before the eyes, or if a loud noise be suddenly made, this descent of the diaphragm, and this closure of the glottis, immediately take place. Bright colours will have the same effect as the use of a looking-glass;—at least when the disease has become very severe; nay, at length,—from the recollection of what has been suffered,—the very mention of swallowing will produce extreme agitation.

Every muscular effort, of whatever kind, has the same tendency; and if the patient be compelled to make an effort to swallow, when he really cannot, it will throw him, not only into agitation, but into absolute convulsions. There is extreme anxiety of mind and despondency; and the patient looks around him, with an eye of suspicion. He has a great aversion to strangers; and the countenance is expressive of his anxiety and distress. We notice, in this disease, very frequent sighing. Breathing is not carried on in a regular uniform manner, but is altered. The patient is extremely restless; tosses about his hands; rolls his eyes; and whatever he attempts to do, he overdoes. Such is his agitation, that if he attempt to rise, he makes more effort than is necessary; or if he attempt to take any thing into his hand, or to swallow, he dashes the cup to his mouth, and gets it all down at once.

*Irritability of Mind and Body.*—There is also such extreme irritability, both of body and mind, that violent fits of passion are induced; and these are more particularly observed, on a proposition being made to swallow; and, in their fury, patients will sometimes bite. Not that they will bite like a mad dog; but the temper is so irritable, in this disease, that they will bite a stranger. This I have seen myself; but I believe it depends, very much, upon the natural temper of the indi-

<sup>a</sup> Page 132. The following extracts illustrate the fact mentioned above:—"He swallowed his bolus before us with great determination, though not without much pain and difficulty." (Page 141.) "He took his bolus before us, with great-self-command; but, in the act of swallowing, he had a convulsive paroxysm, very much resembling those which occur in tetanus;—his body being drawn backwards, with great violence." (Page 145.)

vidual. The mind is often so strong, in the midst of all this, that at the moment they have attempted to bite or strike, they will apologize, instantly regret it, and endeavour to make all the amends they can. They are conscious of their morbid irritability; and they beg others to get out of the way, lest they should injure them. They will make very great efforts to swallow, in order to please bystanders; but, for the most part, after declaring they will swallow, or after taking up the cup into their hands, as soon as they have got it near their mouth, they turn their heads away, and declare it is impossible. Sometimes, again, they have more firmness of mind. They will open their mouths; put the liquid into it; and then a regular paroxysm of the disease will occur. They are seen sometimes so to command themselves, that they will not only drink, but even wash their hands. I had under my care a patient, who (to please me) washed his hands, stirred the water about, and played with it.

*Symptoms in the Latter Stage.*—Those paroxysms which I have mentioned as coming on in the disease, sometimes take place without any external excitement. When the disease has become more violent, these paroxysms occur, from time to time, without any external circumstance having occurred to provoke them. There is, for the most part, sleeplessness; or, if the patient do drop asleep, he wakes in great agitation, and is sometimes delirious. The delirium, when it does occur, is generally of a peculiar nature; and the patient will talk violently of the past, as though it were present; and yet, in a moment, he will become calm and perfectly rational. At last, however, there is sometimes complete delirium. The eyes, towards the close, do not roll; but become red and glassy. The pupils are dilated; and the mouth is very clammy. There is extreme thirst; and, from the clammy nature of the secretion, the patient suffers as much as if his mouth were dry. It very frequently makes the sufferers cry out for something to relieve their thirst; and yet, when fluid is brought, for the most part they cannot take it. From the clamminess of the mouth, they are continually hawking, and scraping their tongue against their teeth; and, in the midst of their rage, they will spit at those about them. They will sometimes put their fingers into their mouth, and pull out a very viscid secretion. The pulse is very rapid and irregular; and during their agitation it is particularly so. It is for the most part feeble at last; but it is constantly quick, even when respiration is slow. Patients generally, at last, sink very rapidly. We are surprised, on our visit, to find them dead.

*Duration.*—The duration of this affection may be from rather less than twenty-four hours, to six or seven days; but the patient generally dies in two or three days; or, at the utmost, on the fourth day from the first appearance of the true signs of hydrophobia;—the dread, the difficulty of swallowing, and the extreme sensibility of the surface. I had two patients with this disease;—little girls; who died in less than twenty-four hours from the symptoms being first observed. In two American cases which I have read, (one occurring in a subject under four years of age, and the other in a person aged seventy-three,) both patients died on the sixth or seventh day;—showing that the duration of the disease has not any relation to the age of the patient. I might have imagined, from having had two patients, under ten years of age, die in less than twenty-four hours, that the young die soonest; but here is a case of a child and an old man, both of whom lingered the same length of time; and I have found this verified in other cases. Old persons will sometimes die very quickly; and young ones will sometimes live as long as I have stated. This is the general character of the disease.

*Order in which the Symptoms Appear.*—The first symptoms in hydrophobia are uneasiness or feverishness, a general feeling of indisposition, and a dizziness in the head; together with chilliness and flushes; and these symptoms may continue some days. Dr. Parry furnishes instances, where these symptoms lasted five or six days; and I believe they may go off entirely;—just as other specific diseases (diseases from morbid poison) are seen to do. We all know, in the case of gonorrhœa, that a person will have every trait of the affection one morning, or one evening, and it will entirely go away; although he knows he has been where he was

very likely to contract the disease. Continued fever will thus go off; so I believe will the plague; and ague certainly will do so. A person who has been exposed to malaria, will have a mere shivering; which will go away and not return. I believe it is just the same in hydrophobia. I saw two little girls (sisters) who were bitten by a dog at the same moment, and in the same place,—the face. One of them died; and the sister had exactly the symptoms I have described,<sup>a</sup> as ushering in hydrophobia; but, after lasting four or five days, they ceased; and she did perfectly well.

After these symptoms have continued some little time, perhaps a couple of days, suddenly the person is surprised by a difficulty in swallowing liquids; and finds a spasm of the throat, and an impossibility of swallowing. At the same moment, perhaps, he has great anxiety and great terror; or perhaps a draft of wind suddenly blows upon him; his breath catches; and he wonders (as do also those around him) what is the matter. That was the case in a boy whom I once saw. The first symptom of his disease, was induced by a draught from a door. A person went into his bed-room, in the morning; and, on opening the door, the draught occasioned by it came full upon him; and he was observed to go almost into fits. The sudden impression of the air took away his breath; and agitated him to this violent degree.

*Sometimes Remittent.*—In the course of the disease, there is sometimes a remission. The disease does not *necessarily* go on in an uniform tenor. In a case published by Dr. Satterley, one of the physicians to the Middlesex hospital, the patient had fits of biting; and between these he was perfectly well;—even took warm fluids, and had a sound sleep. The disease is not so continuous but that, in some persons, there will be a decided remission; so that the patient can absolutely swallow liquids very well, and will go into a quiet and sound sleep. Some say (but one can hardly believe it) that there are absolute *intermissions*; that the disease altogether,—every symptom of it,—will sometimes cease for a time; and will even become *periodical*! There are cases of remission and recovery mentioned, as having occurred in dogs; but it is doubtful whether recovery ever took place in the human subject.

*Peculiar Symptoms.*—Now and then peculiar symptoms arise;—such as are not observed in ordinary cases. One case of this kind occurred at Guy's Hospital; the particulars of which were published by Dr. Marcet, in the first volume of the “*Medico-Chirurgical Transactions*.”<sup>b</sup> From some disturbance of the brain, or of the olfactory nerves, the patient complained of an intolerable stench around him.<sup>c</sup> This is sometimes observed in ague. In some cases, (from irritation, I presume, in another part of the nervous system,) there has been an erection of the penis; and an oozing from the mouth of the urethra. These are all accidental circumstances.

*Dysphagia not always Present.*—Sometimes, in this disease, there is no inability to swallow either liquids or solids. There is a mere tremor;—a mere agitation; and that not very considerable; together with great debility, rapid pulse, and extreme restlessness. This has been said to occur, chiefly, when a cat has inflicted the bite. Dr. Fothergill mentions this circumstance, in the fifth volume of the “*Medical Observations and Enquiries*,” but it is not universal; for I saw a man who had been bitten by a mad cat, and who swallowed perfectly well. I saw him eat a basin (holding a pint) full of bread and milk, an hour or two before he died. All his symptoms were rapid pulse, extreme restlessness, and great agitation. He thought nothing about the cat;—his mind seemed at ease on that subject; and he sat up, if desired. During the whole of the case, there was no delirium whatever. The man died, I believe, on the second day after the commencement of the symptoms; and a short time after I saw him. He was not my patient; but I saw him in the wards of the hospital.<sup>d</sup> He had been bitten six weeks before; but

<sup>a</sup> See Page 639.

<sup>c</sup> “*Medico-Chirurgical Transactions*,” Volume 1; Page 152.

<sup>d</sup> St. Thomas's.

<sup>b</sup> See Note (a) to Page 638.

had forgotten it;—the friends alone remembering the circumstance. A case is published by Dr. A. T. Thomson, in the “Medico-Chirurgical Transactions;” where hydrophobia, well formed in every respect, arose from the bite of a cat.<sup>a</sup>

*All Ages liable to the Disease.*—This is a disease which affects children as well as adults. We seldom hear of women labouring under it; but children of both sexes, and men more frequently than either, become its victims. I have already cited two cases, from the American Philosophical Transactions, where the disease occurred in patients, one of whom was a child four years of age, and the other a man who had attained his seventy-third year;<sup>b</sup> so that we have here the extremes of life. Infants may not be exposed to a rabid animal; and the reason it attacks men more than females, is because the former are so much more out of doors than the latter. Dr. Parry mentions a child, only three years and a half old, having the disease.

## SECTION II.—PATHOLOGY AND CAUSES.

*Morbid Appearances.*—After death, there is sometimes found a fulness of the vessels of the head; and sometimes marks of decided inflammation, not only in the head, but within the spine. Sometimes there is an effusion of *serum*, either pale or bloody; and sometimes *lymph* has been found effused, particularly about the base of the brain. In the case of an old man who died without suspecting the nature of his affection, and the particulars of which are contained in the “Medical Gazette,”<sup>c</sup> there was inflammation of the whole of the base of the brain, of the spinal cord, the cerebellum, the “*cruri cerebri*,” and the two “*thalami nervorum opticorum*,” and the “*corpora striata*” were redder than natural. This was an *inflammatory* case of hydrophobia; but in other cases no such thing has been discovered. I have seen patients opened, where there was no effusion, or redness, or any thing that would lead the best anatomist to say, that the brain and spinal marrow were not perfectly healthy;—just as is the case in tetanus.

Sometimes red spots are found in the fauces, larynx, trachea, and bronchia; and likewise in the stomach. In a great number of cases, there is considerable redness of the glottis and epiglottis; and great congestion of the lungs. The latter circumstance would be expected, *à priori*; in consequence of the difficulty of breathing, and the spasm which takes place and disturbs their functions. Sometimes, however, nothing has been found from head to foot; and Magendie says, that sometimes he has opened dogs and found nothing. I mentioned, that red spots are sometimes found in the stomach; but sometimes there are none at all. It appears, therefore, that the disease (like tetanus<sup>d</sup>) is not necessarily of an inflammatory nature. Now

<sup>a</sup> Volume 13; Page 298.

<sup>b</sup> See Page 639.

<sup>c</sup> Volume 3; Pages 123 and 124; No. 56; December 27, 1828. The morbid appearances, as there detailed, were the following:—“On opening the chest, the heart was observed to be free from disease, with rather more water in the pericardium than natural; the lungs were completely gorged with grumous blood, and the pleura adhered on the right side. On removing the cranium (which was remarkably thin), and cutting the substance of the brain, numerous red spots presented themselves in the medullary portion; there was about a table-spoonful of water in each ventricle; the plexus choroides was turgid; the *corpora striata*, *thalami*, and basis of the brain were everywhere preternaturally injected; and the cerebellum, and *crura cerebri* and *cerebelli*, in a high state of inflammation. On removing the spinous process of the vertebra, the whole cord was considerably inflamed; and opposite the two last cervical and dorsal vertebrae, the cellular substance was studded with dark patches of coagulated blood, the theca vertebralis thickened, and the cord in an active state of inflammation. The larynx and pharynx bore not the slightest vestige of disease. The preparation of the cord is deposited in the Museum of the London University. The post-mortem examination of this case, tends to prove the correctness of Professor Thomson’s theory of the proximate cause and seat of this afflicting malady, and the plate accompanying a case recorded by him in the thirteenth volume of the ‘Medico-Chirurgical Transactions’ [Page 298], gives a faithful delineation of the state in which the spinal cord was found in this case.”—For the previous history of this case, see Note to Page 644.

<sup>d</sup> See Page 630.

and then signs of inflammation may be found; but in many cases they are not; and it is clear, that the nature of the disease is not essentially inflammatory.

*Nature of Hydrophobia.*—Some gentlemen, from observing redness and congestion about the air-passages, and others from observing similar appearances in the alimentary canal, have ascribed hydrophobia to a morbid state of these parts; but I think the extreme sensibility of the surface of the body, the extreme agitation on attempting any muscular effort, the convulsive movements that take place in swallowing, the spasmodic catching of the breath,—even on touching the lips with liquid, or the application of cold air to the surface,—the anguish and irritability of the mind (anguish not arising from *pain*), the great suspicion, and at last delirium, all show something more than an affection of the lungs or stomach. Such symptoms as these indicate an affection of the nervous system. In tetanus there is no morbid irritability either of body or of mind.<sup>a</sup> There is only a spasm of the voluntary muscles; and this, in all probability, arises from an affection of the origin (or termination) of the nerves, in the head or the spinal marrow. Such a state, I said, is not necessarily inflammatory; though occasionally inflammatory signs are found.<sup>b</sup> But in hydrophobia there is no irritation of the voluntary muscles in general; but a morbid sensibility of the nerves of sense;—particularly those of touch, and of those running to the muscles of deglutition and respiration. In addition to this, the mind is altogether in a state of suspicion and irritability;—showing that it is the centre of the nervous system, that is particularly affected. What it is exactly, it is impossible for me to say; but so far we may trace it. One cannot attribute it to the nerves; or to that part of the brain connected with the nerves of deglutition and respiration; because we see extreme suspicion of mind,—extreme mental anguish; and we see that many parts of the nervous system are affected.<sup>c</sup>

The blood, in this disease, is not buffed; neither is the urine high-coloured. On the contrary, it is pale. The tongue is perfectly clean; but the mouth is clammy, and is filled with viscid mucus. The pulse is not full. It is not at all an inflammatory pulse; but it is, nevertheless, rapid and irregular;—frequently very much so. I may mention, that many persons have not found any inflammation whatever; but there have been cases where local inflammation has existed, particularly at the base of the brain. The thirst in the disease does not arise from an inflammatory state, or from feverishness; but is either a part of the disease, arising from the disturbance of the nerves, or from the clammy secretion of the mouth. When all the parts of the mouth are dry, or are covered with only a viscid secretion, and not moistened by a thin fluid, thirst is the necessary consequence. There is, in general, only morbid heat from time to time, when the patient is particularly excited. I will not pretend to say what the state of the nervous system is;—any more than in tetanus.<sup>a</sup> We may limit the disease to the nervous system; particularly to the nerves of touch, and the nerves running to the muscles of deglutition and respiration; together with general excitement of the brain itself; but what the particular state is, it is impossible to say.

*Is it Contagious?*—When speaking of contagion in general, I mentioned that the contagiousness of this disease had been denied.<sup>d</sup> There was a surgeon, (I think at Brighton, though I have not the pleasure of knowing his name,) who lately denied that this was a contagious disease; and, from his conviction that his opinion was correct, he inoculated himself with some of the saliva from the rabid

<sup>a</sup> See Page 632.

<sup>b</sup> See Page 630.

<sup>c</sup> The disease seems to begin in the pharynx, and to spread through the body. The pharyngitis is rather a *consequence* than a *cause* of it. Some think it arises from turgescence of the spinal marrow; but that may be a consequence of the general convulsions. Rush places the cause in the stomach and bowels; Morgagni in the brain; and it has also been placed in the bronchi; and attributed to an exanthematous disease under the tongue. Some have maintained, that it is not a specific disease; but a variety of tetanus in men, and hysteria in women; but the symptoms are different from both. The patient often dies of a universal convulsion, or a spasm of the diaphragm or respiratory muscles, or nervous apoplexy from exhaustion. The *organic* disease appears to be the result of the *functional*.—Dr. Fletcher.

<sup>d</sup> See Page 301.

animal; and did so with perfect impunity. So, perhaps, he might have exposed himself, with impunity, to the danger of contracting syphilis or gonorrhœa; but that would be no proof that there was no such contagion. However, unfortunately there is no novelty in this denial of contagion. Gerard also denied it; and there could be no other reason for denying it, than a desire to be peculiar. De Foe denied the contagion of plague; but he was soon convinced of his error.<sup>a</sup> I mentioned that two students, at Paris, denied the contagion of syphilis; and inoculated

<sup>a</sup> I could give several instances, within the compass of my own knowledge, where, when a servant had been taken sick, and the family had either time to send him out or to retire from the house and leave the sick person, they were preserved; whereas when, upon one or more sickening in a family, the house has been shut up, the whole family have perished, and the bearers have been obliged to go in to fetch out the dead bodies;—not being able to bring them to the door; and at last none left to do it. This put it out of the question to me, that the calamity was spread by infection; that is to say, by some certain steams or fumes (which the physicians call “effluvia”), by the breath, or by the sweat, or by the stench of the sores of the sick persons, or some other way, perhaps beyond even the reach of the physicians themselves; which effluvia affected the sound, who came within certain distances of the sick;—immediately penetrating the vital parts of the said sound persons, putting their blood into an immediate ferment, and agitating their spirits to that degree which it was found they were agitated; and so those newly infected persons communicated it, in the same manner, to others: and this I shall give some instances of, that cannot but convince those who seriously consider it. And I cannot but with some wonder find some people, now the contagion is over, talk of its being an immediate stroke from heaven, without the agency of means,—having commission to strike this and that particular person, and none other; which I look upon with contempt, as the effect of manifest ignorance and enthusiasm: likewise the opinion of others, who talk of infection being carried on by the air only;—by carrying with it vast numbers of insects, and invisible creatures; who enter into the body with the breath, or even at the pores with the air; and these generate or emit most acute poisons, or poisonous ova (or eggs); which mingle themselves with the blood, and so infect the body;—a discourse full of learned simplicity, and manifested to be so by universal experience. I have so many examples fresh in my memory, to convince me of it, that I think none can resist their evidence; and I must be allowed to believe, that no one in this whole nation ever received the sickness or infection, but who received it in the ordinary way of infection from somebody, or the clothes, or touch, or stench of somebody, that was infected before. The manner of its first coming to London proves this also;—namely, by goods brought over from Holland, and brought thither from the Levant; the first breaking of it out in Long Acre, where those goods were carried and first opened; its spreading from that house to other houses, by the unwary conversing with those who were sick; the infecting the parish officers who were employed about persons dead; and the like. These are known authorities for this great foundation-point;—that it went on and proceeded from person to person, and from house to house, and no otherwise. In the first house that was infected, there died four persons; a neighbour, hearing the mistress of the first house was sick, went to visit her; went home, and gave the distemper to her family; and died, and all her household. A minister called to pray with the first sick person in the second house, was said to sicken immediately and die; with several more in his house. Then the physicians began to consider; for they did not at first dream of a general contagion; but, being sent to inspect the bodies, they assured the people that it was neither more or less than the plague, with all its terrifying particulars; and that it threatened a universal infection;—so many people having already conversed with the sick or distempered, and having (as might be supposed) received infection from them, that it would be impossible to put a stop to it.

The people of London thought themselves so plague-free now, [when the disease began to decline,] that they were past all admonitions. They seemed to depend upon it, that the air was restored; and that the air was like a man that had had the small-pox;—not capable of being infected again. This revived the notion, that the infection was all in the air;—that there was no such thing as contagion from the sick people to the sound; and so strongly did this whim prevail among the people, that they all ran together promiscuously,—sick and well. Not the Mahometans, who—prepossessed with the principle of predestination—value nothing of contagion, let it be what it will, could be more obstinate than the people of London. They that were perfectly sound, and came out of the wholesome air (as we call it) into the city, made nothing of going into the same houses and chambers, nay, even into the same beds, with those that had the distemper upon them, and were not recovered. Some paid for their audacious boldness with the price of their lives. The physicians had more work than ever; only their patients generally recovered. There were more people infected and fell sick now, when there did not die above a thousand or twelve hundred a week, than when there died five or six thousand a week;—so entirely negligent were the people, in the great and dangerous case of health and infection.—*Journal of the Plague-Year (1655). By Daniel Defoe.* Edition published in the “Pulteney Library,” Pages 27, 66, 67, and 78.

themselves with the virus.<sup>a</sup> Both of them became affected with the disease; and one committed suicide. If the disease were an imaginary one, why should it attack children, who have never heard of it? Two little children, whom I attended in this disease, one a year after the other, could have had no idea of it; and they died, perfectly unconscious of what was the matter with them. Adults have died of the affection, without recollecting that they had been bitten. The thought of the disease has not preyed on their spirits in the least; but they have been suddenly surprised by it; and it has never occurred to them what the disease was, or that they had formerly been bitten. Mr. Godrich (of Brompton) mentions the case of an old man, sixty years of age, who had been bitten and died of the disease; but who was unconscious of its nature to the last.<sup>b</sup> Two cases are mentioned by Dr.

<sup>a</sup> See Page 304.

<sup>b</sup> On Thursday morning, November 25 [1828], I was called up, at seven o'clock, to see a man who (I understood) was exceedingly ill, and waiting in the surgery very impatiently for my arrival. I found my patient (Mr. Barham) a fine-looking old man, about sixty; labouring, at intervals of about five minutes, under strong spasmodic paroxysms, affecting the muscles concerned in breathing and deglutition. There was a wildness and an impatience depicted in his countenance, totally different from any thing I had ever observed in other spasmodic affections. His bowels were open, tongue clean, skin moist, pulse full, and a little accelerated. I took away twenty ounces of blood, and prescribed a mixture containing half a drachm of laudanum for a dose every hour, until I should see him again. He walked home, half a mile from my house (Gloucester Road, Old Brompton); and left me ruminating on the possible cause of so much mischief occurring suddenly in a fine healthy subject. At ten, a message was sent that he was much worse, and requesting me to call as soon as possible. He received me very tranquilly, and said he was very glad I had come to see him, for he was very ill. His symptoms were now more distressing than when I first saw him; he looked wildly and suspiciously at every one entering his apartment; and his breathing was accompanied by a short convulsive sobbing. On looking at his medicine, I perceived that he had taken none; and, on my expressing my surprise, he assured me that it was impossible for him to swallow a single drop; as the attempt had been followed by violent spasms; and produced so much distress, that he had desisted. At this period, no one had the slightest idea of the origin of his malady. I poured out some medicine into a teacup; the very act of which produced much excitement and alarm. My first impression as to the true nature of his disease, arose at this period; from the circumstance of his requiring a teaspoon, with which he endeavoured to take some of the medicine. The attempt produced much excitement and alarm; and, after two or three painful efforts at deglutition, with one desperate effort he swallowed a teaspoonful; threw away the spoon; and begged, unless I wished to destroy him, that he might have nothing more to swallow. I now left his room; and inquired of a bystander whether any thing particular had occurred to him within the last few weeks. On recollection she said—"About a month since, late at night, a strange dog came into the premises, and fought with his own dog. He got out of bed to separate them; and the strange dog bit him, in two places, on the left arm and hand; and bit a puppy, which died (about a fortnight afterwards) in a strange way, which was thought to be some kind of a fit." To ascertain if this occurrence had produced any effect on his mind, while again bleeding him, I said—"You have been in the wars, Sir; and had your hand and arm torn: how did it occur?" "O!" said he, carelessly, "that was done by a dog a long time since; but it healed." The circumstance was never again mentioned to him; and he died in total ignorance of the cause of his malady. The wounds were perfectly cicatrized; nor was there going on the least action indicative of recent absorption. He bore the bleeding pretty quietly. Forty ounces were removed; and, on cooling, presented strong marks of inflammation. He was ordered four minims of hydrocyanic acid, every hour, in a little water.

Twelve o'clock.—With much difficulty, he has taken two doses of the acid; pulse full and hard, 110. Thirty ounces more blood were removed.

Three o'clock.—Has taken two more doses; complains of a dreadful sense of suffocation, and implores that nothing more may be given him. Pulse full, and beating at 120 to 130. The acid was ordered to be continued.

Eight o'clock.—Pulse full and hard. He has taken in all twenty-four minims of the acid; but so painfully distressing has the deglutition now become, that all attempts at repeating his medicine are discontinued. He was again bled to thirty ounces. During the bleeding, he looked wildly at the basin, and requested that no more might be spilt (a drop or two had fallen);—repeating frequently, in great agitation, as the blood was running—"Take care! take care!" Between two and three o'clock, next morning, my assistant (Mr. Davies) visited him. He found him tolerably passive, but observing every movement with intense anxiety. Pulse full and hard; face flushed; eyes denoting cerebral irritation. He had been at times outrageous. On his being intimated that bleeding was again necessary, a paroxysm more intense than any preceding, came on; and with great effort he submitted. As the blood

Parry, in which the bite was forgotten; and another case in which the bite was spoken of with the greatest indifference. In the last case I had, the boy knew that he was bitten; but he thought nothing of it; and never seemed to attach the least importance to it. That there is such a disease, that its character is so peculiar, and that it unquestionably arises from a morbid poison, cannot admit of a moment's doubt. It is also to be remembered, that many persons who are bitten, and fancy they will have the disease, never have it at all. I have seen many persons bitten by dogs, wash the parts, take physic, have the parts cut out, and do all they could to torment themselves into the disease; and yet they have never had it. The character of the disease is too plain, to allow of any doubt as to its existence.

*Exciting Cause.*—The exciting cause of the disease, however, is well known. It is a secretion from the mouth of a rabid animal. It is said to be the *saliva* which is poisonous; and it *may* be that fluid; but I do not know that it is *proved* to be the saliva, rather than the mucus. The saliva of the human subject is equally poisonous with that of the brute; or, at least, it is *also* poisonous; for Magendie says, that he inserted the secretion from the mouth of a rabid human being (that is to say, a person labouring under hydrophobia) into dogs; and they became the subjects of the disease.

Dr. Hertwig says, that he inoculated fifty-nine dogs with diseased secretion from hydrophobic dogs; and that only fourteen took the disease. He states, that he made experiments with the blood; and found that it was equally poisonous with the secretion of the mouth. He says the saliva will act, in producing the disease, at all periods of the affection; and in twenty-four hours after death, if it be taken from the body, it will still give rise to it; but he says, that if the poison be swallowed, it is perfectly inert. The poison of serpents, we are told, may be swallowed with impunity.

*Period of Incubation.*—After the poison has been applied, there is usually an interval before the appearance of the disease, of from one or two weeks, to three months. I believe the average interval is from one to two months. The disease is said to have appeared, sometimes, in five or six days; and a case was mentioned, in which the affection appeared to come on the next day;—at least, it was so said. In other cases, the disease has not appeared for nine or twelve months. There is a case mentioned in the “Philosophical Transactions,” where the affection did not come on for nineteen months. Dr. Bardsley, in the “Literary and Philosophical Transactions of Manchester,” has furnished an account of a case where the disease did not occur till twelve years after the bite. The case has given rise to a great deal of doubt. In the first place, we may almost doubt whether the disease was genuine; but, allowing that it was, then there is a doubt whether or not it arose from the morbid poison. As the wound had been inflicted twelve years before, there is great difficulty in supposing that the poison had existed so long; and, on the other hand, if it was not owing to this bite, it must have sprung up *de novo*. Dr. Parry, who has written on Cases of Tetanus and Rabies Contagiosa, thinks the case was not genuine; and he also considers that the shortest well-authenticated interval, is two or three days; but I have reason to believe it has occurred at a shorter interval. I also think, that Dr. Parry is wrong on another point; for he states that he can find on record only thirty-eight well-authenticated cases of hydro-

phobia. He became more and more alarmed; till at length he became quite unmanageable; he raged violently at his nephew, who was holding the basin: and ordered it, peremptorily, to be taken away. Thirty or forty ounces were taken away. It was found necessary to put on the strait-waistcoat. About four o'clock, Mr. Davies wished him to take more of his medicine. He said—“I can take no more;” and, on Mr. D.'s reaching the bottle to put out a few drops, he became violently agitated, threw himself from side to side; and, as well as the incessant spasmodic sobbings would allow, he begged that not one more drop of any thing might be offered him, and that the bottle might be taken from his sight. He did not become tranquillized until its removal. He lingered on till ten (A.M.), in the same state; a few minutes before which he insisted on getting up, and walked a short way down his garden; returned, lay down on his bed, and died.—“*London Medical Gazette*,” Volume 3; Pages 123 and 124. (No. 56; December 27, 1828.)

phobia. Now, in my limited period of practice, I have seen six or eight cases in London; and, during the same period, there have been others which I did not see. Two of these cases occurred in private practice; and four or five in the hospital; and, having seen these myself, I must think the disease is far more frequent than Dr. Parry intimates. The fact was, Dr. Parry saw a great number of cases called "hydrophobia," that were not instances of the disease; and he was too scrupulous in allowing that cases which he found recorded in books were genuine hydrophobia; and therefore he put too many in the spurious list. The interval, however, is various. It is said to be about the same in the dog as in the human subject. Among Lord Fitzwilliam's hounds, in Yorkshire, the interval varied from six weeks to six months. His pack were bitten by a rabid animal; and the disease appeared at various intervals, from six weeks to six months.

*The Poison must be inserted into a Wound.*—Persons usually escape, if the poison be not inserted into a wound. Cælius Aurelianus mentions the case of a woman, who was seized with the disease three days after eating some game which had been sent to her; and which was supposed to contain hydrophobic poison, in consequence of having been killed by a mad dog. If the case was true, there was probably a crack in her lips. Dr. Bardsley mentions a case, which occurred (at the common interval) in a shepherd, who had only been licked by a dog. His dog was rabid; but then shepherds continually have cracks in their hands; and nothing is more likely, than that there was a crack in some part of his hand.

*Communicable by an Animal not known to be Mad.*—It is possible for the brute to give the disease to the human subject, when the animal is not known to be mad. Many cases have occurred of persons being bitten by dogs, and becoming mad, though the dog was not, till afterwards, supposed to be mad. The disease must have existed at the time, or the dog could not have communicated it; but it exhibited no signs of madness,—so as to be considered in that state. It has been imagined, that all bites of animals have something venomous in them; and we are told that many bites of brutes have caused signs of hydrophobia, epilepsy, and even death; but, in all probability, these were nervous symptoms, induced by fear.

*Many are not attacked when bit by a rabid Dog.*—On the other hand, most persons bitten by rabid animals do not suffer hydrophobia. Dr. J. Hunter mentions, that twenty-one persons were bitten by a dog; and among them only one became affected with the disease; although none of them took any steps to prevent it. Dr. Vaughan mentions, that between twenty and thirty persons were bitten by a mad dog. Some did nothing; others took the "Ormskirk medicine,"<sup>a</sup> and had a dip in the sea; and yet, of this number, only one had the disease. Dr. Parry mentions, that several sheep and dogs were bitten; and that, among these, not one sheep had the disease, and only two dogs; and I may remark, that one of these dogs was bitten before the sheep, and the other just afterwards. I had a case of this disease in a little girl, who was standing at her father's door, when a dog snapped at her face, and did the same at another sister; and then passed on. At the expiration of six weeks, or two months, the sister who was bitten second had hydrophobia, and died;<sup>b</sup> but the other sister never had the disease, or the premonitory symptoms went off; and she may be alive now. We might imagine, that the girl first bitten would have been most likely to suffer the disease; because the teeth must have been covered with secretion; however, it was the second that died from the disease. Nothing, I understand, was done in this case; except that nitrate of silver was applied.

Much depends upon whether the part is bare or not. Hence we find that, by far most frequently, persons who have hydrophobia through a bite, have had the wound inflicted on the hands or face. In three cases that I had under my care, in private practice, one patient was bitten on the face, and two on the hands. If the part be not bare, the tooth is wiped as it passes through the clothes; and therefore no fluid is conveyed with the bite. It is a bite on the bare surface, that is gene-

<sup>a</sup> See Page 650.

<sup>b</sup> See Page 649.

rally productive of the disease. Some persons have so little disposition to the affection, that notwithstanding they are bitten on bare parts, and no precaution is taken, they do not suffer the disease; and sometimes persons will not experience it, till they are thrown out of health; or till they are frightened; or till they catch cold; or till something happens to disturb the constitution, and then it appears. This is precisely what happens in the plague, in ague, and in other affections.<sup>a</sup>

*The Wound generally heals before the Attack.*—The wound is generally healed when the disease appears; and, as I stated formerly,<sup>b</sup> it is sometimes entirely forgotten. Some say, that if there be a wound, it becomes livid when the disease appears; or that it looks yellowish; and that it re-opens. Sometimes, when it appears, there is pain and numbness in the bitten part, extending along the course of the nerves. This was the case in an instance I had under my care. The boy had been bitten in the hand, and the part had been cut out entirely; but pain was felt along the nerves, and extended to the neck, at the time that the disease began. It was curious that there was no pain in the wound, or in the hand, or in the upper arm. More frequently than not, it is along the course of the *nerves*, and not along the course of the *blood-vessels*, that the pain has been observed.

*Various Animals liable to it.*—The animal which most commonly gives the disease, is the dog; but other brutes will have it; and probably *all* of them will imbibe it, and also communicate it. The wolf, the fox, and the dog, are all of the canine species; and they are well known to give and receive it: and they appear to originate it likewise;—that is, there is every reason to believe it will originate in them;—unless the poison may remain dormant as long as some people imagine.

*Cause, when produced De Novo.*—Unless it can exist in a dormant state for a long time, there is every probability that hydrophobia is produced *de novo*.<sup>b</sup> The cause of it, if it can arise *de novo*, is not well known. It is not putrid meat; for the Caffres, in Africa, feed all their dogs on putrid flesh; neither is it *salt* meat; neither is it a want of drink. The disease is unknown in Syria;<sup>c</sup> and, according to Dr. Parry, in the interior of the Cape of Good Hope, where there is plenty of heat; and, in some instances, plenty of putrid meat.<sup>d</sup> It is said never to be known in South America; but then two-thirds of the pups there die of “the distemper;” and some persons contend, that the distemper prevents the spontaneous occurrence of hydrophobia. I do not know whether that is correct.

### SECTION III.—DIAGNOSIS.

*Spurious Hydrophobia.*—Spurious cases of nervous fever, or nervous irritability, are very different from these. If the case be spurious, the difficulty in swallowing generally occurs far too early after the bite. A certain period (usually some weeks) elapses between the bite, and the appearance of the disease; but where persons have a difficulty in swallowing from mere nervous terror, it generally begins at an early period. There is much too early delirium and general convulsions; the agitation of the mind arising from fear, brings on a degree of insanity.

In the spurious form, again, there is generally no catching of the respiratory organs. The great feature of this disease is the sudden inspiration, as though the patient were plunged into cold water; and this produced not only by an attempt at swallowing, by the sight of water, and by *speaking* of water, but by a breath of

<sup>a</sup> See Page 314.

<sup>b</sup> See Page 645.

<sup>c</sup> Considering the heat of the summer, climate, and the thirst which the dogs [in Syria] then suffer, it seems strange that they are not subject to hydrophobia. Indeed, some distrust as to the popular ideas connected with that dreadful disease might be deduced from the fact, that hydrophobia is least known in the warmest climates. In Constantinople, cases of this disease sometimes occur, although they are exceedingly rare; but they become increasingly infrequent as we advance southward, and in Egypt are altogether unknown.—“*Pictorial History of Palestine*,” Part 17. (“*Physical History*,” Chapter 8; Page 357.)

<sup>d</sup> It has been attributed to the want of sexual intercourse.

cold air, or the crawling of an insect upon the surface, or by any sudden impression. Patients who only *fancy* they have hydrophobia, have a difficulty of swallowing; but they forget to have a catching of the breath. They are not aware that that is a symptom. They only think of the difficulty of swallowing liquids; and therefore that symptom only arises. They are not conversant enough with the disease, to know another remarkable symptom; and therefore that never takes place; or, if it do, it is only a simple local affection, producing irritation of the organs of respiration. So characteristic of the true disease is this sudden but deep inspiration, that when a paroxysm takes place during sleep, the person always awakes with a sudden deep inspiration. In the true disease, patients (in order to please their medical attendants) will make every possible attempt to swallow. They will say they cannot; but then they will try.<sup>a</sup> They will make the greatest efforts, and succeed to a certain length, and very frequently succeed entirely; whereas, if a person have the *fancied* disease, he concludes it is quite impossible. He will not *hear* of such a thing; and considers it almost an insult to have it supposed that he can swallow. In the fancied disease, the patient has not sufficient firmness of mind to make the attempt; and shudders at the very sight or name of liquid; whereas, in the true disease, patients will not only do this, but will even put their hands into cold water; and, as I have already said,<sup>b</sup> will stir it about.

The people who *fancy* it, are not *surprised* by the disease;—it does not take them *suddenly*. They anticipate it; they look forward to it with a low melancholy; and then, at last, they begin to find they cannot swallow; whereas, in the *true* disease, the symptoms come on suddenly. In the spurious affection, also, there are generally a variety of nervous symptoms; such as “globus hystericus,” and other symptoms common to nervous derangement. There are not the usual effects, in the spurious disease, from the sudden impression of cold air, and the sprinkling of cold water. The former certainly does not produce the agitation, which it occasions in the true disease. It is to be remembered that the disease may be spurious, when a person has actually been bitten by a mad dog. He may have been bitten, and the poison may not have taken effect; and yet the person has agitation of mind, sufficient to produce difficulty of swallowing. It is probably in such cases, that persons have been said to recover from hydrophobia; but they have done so such thing. The persons have been bitten by a mad dog; and, for want of the practitioner being fully acquainted with the disease, he has not made a sufficiently accurate diagnosis; and has supposed that recovery has taken place from the disease.

*From Distemper.*—Dr. Jenner, in the first volume of the “Medico-Chirurgical Transactions,”<sup>c</sup> lays down the diagnosis between hydrophobia and “the distemper.” He says, that in the latter the eye is dull;—the dog looks stupid, and has an insatiable desire for water. “The distemper” is a violent kind of catarrh; and we may therefore imagine that the eye will look heavy, and that the animal will become thirsty. The dog wanders from home; and, at length, he is disposed to be sluggish. But in hydrophobia, Dr. Jenner says, the eye of the dog is bright. He looks furious; and generally declines water. When a hydrophobic dog bites, it sneaks off directly, and is not found again; or, if found, it is dead. It goes away from the place, and is frequently afterwards found dead. It only gives a sneaking bite, and does not continue its attack like another dog; and after it has bitten an individual, it skulks into a corner, and then runs off. Hence it is, that many persons who have been exposed to hydrophobia, will say they were bitten by a strange dog, that was perhaps passing by;—that it attacked them without any provocation, and then made off.

*Character of the Voice.*—A German physician (Dr. Hertwig) says that the voice of the dog, in hydrophobia, is peculiar and pathognomic. He says that the bark of a dog labouring under the disease, ends in a howl; and the mouth at the time of barking is lifted up.

<sup>b</sup> See Page 639.

<sup>c</sup> See Pages 267 and 268.

## SECTION IV.—TREATMENT.

*Excision of the Part.*—With regard to the prevention of the disease, it is certainly our duty to cut out the bitten part as soon as possible; and, perhaps, at any time between the bite and the appearance of the disease. If the part cannot be cut out, I should think it proper to remove the whole limb. I am not sure that excision prevents the disease; because I know, that in many cases in which this has been done, the disease has occurred. A perfectly authenticated case was mentioned to me, in which not a moment was lost; for the person, the instant he was bitten, walked across the way to a surgeon, and had the part freely cut out; but, notwithstanding this, at the usual time he had the disease. It is, however, but common sense to do every thing we possibly can to prevent it; and excision is the most proper plan.

*Cupping-Glasses.*—Some have applied cupping-glasses; and this is a most ancient practice. It is mentioned by Celsus.<sup>a</sup> Dr. Parry also recommends it; and, still more recently, it has been recommended by Dr. Barry; who says that its use has been shown, by experiments with various mineral and vegetable poisons. If these poisons be applied to a wound, and the poisonous effects begin, and the cupping-glasses be applied, in proportion as they act, the influence of the poison disappears. It is therefore recommended to us immediately to apply cupping-glasses to the wound; and to excite the part thoroughly;—so as, if possible, to draw out every particle of the diseased fluid. The stream, of course, will be towards the glass; and, as the fluid will be washed away, circulation and absorption will be prevented at the moment. Then we may cut the part out, and cup again. Whether it would be useful to adopt this plan, I cannot tell. If we could have a fair opportunity to cut the part out at once, I should think that would answer every purpose.

*Caustics.*—Caustics are by no means to be depended upon; but if they be used, they should be very strong;—such as caustic potash, or strong mineral acids; or (what perhaps is better than all) the actual cautery should be employed. I do not know (as I said before) that even excision is to be depended upon; but, after excision, in order to make what is considered certain *doubly* certain, caustic might be employed; or the actual cautery. Some have recommended the chlorides; and it is very possible that they may destroy the poison; but even supposing they will, one cannot be sure that every particle of the poison has come into contact with a part of the solution of the chlorides. We are not sure that every particle has been decomposed; and, therefore, if the chlorides be applied, still I should cut the part out in the first instance, and apply them afterwards. The use of these other things, in addition to excision, may be very great. If the part be one that cannot be cut out,—if the wound be so deep that it is impossible to cut it freely out, and the removal of the part by amputation be not possible, then use the actual cautery, or caustics. When the part is cut out, we are advised not to allow it to heal, but to keep it open; so as to produce a discharge for a length of time.<sup>b</sup> However, I know of plenty of cases where this has been done; and yet the disease appeared; though, certainly, one would fancy it was better than mere excision. After we have cut out the part, then we may apply caustic, or the actual cautery, and keep up a discharge.

*Mercury.*—In the way of prevention, we are strongly recommended to give mercury to ptyalism. A great many cases are recorded, where the disease never appeared after this was had recourse to; and it is stated that, in some instances in which mercury had not been employed, the disease appeared; but there are cases enough on record of the disease occurring, after mercury had been exhibited to the greatest extent. Not knowing what to do in the way of prevention, in the case of the sister of the little girl who died of hydrophobia<sup>c</sup> (two months having elapsed

<sup>a</sup> Liber 5; Caput 37; Sectio 2.

<sup>b</sup> With this view, Dr. Fletcher recommends powdered cantharides.    <sup>c</sup> See Page 646.

since the bite). I exhibited mercury freely. I was not content with its exhibition by the mouth; but she was washed with a strong solution of bichloride of mercury, till a rash was brought out; and then it was discontinued, lest inflammation should come on. In this way her mouth became tender; and she had nothing more than the premonitory symptoms. Whether the mercury had any effect I do not know; but I should think not; because I believe the symptoms went off before the mouth was affected. I should think there is no reliance to be placed on mercury. Dr. Good thinks, that belladonna united with the bichloride of mercury, in large quantity, has acted as a prophylactic in his hands.

*Scutellaria Laterifolia*.—Dr. Spalding tells us, that the exhibition of "*scutellaria laterifolia*" is successful; nay, that it prevented the disease in thousands of cases of men, dogs, oxen, and swine.

*Ormskirk Medicine*.—The "*Ormskirk medicine*" was once held in very high estimation. It is said to consist of powdered chalk, Armenian bole, alum, powder of elecampane-root, and oil of anise.

*Sea-Bathing*.—In London, sea-dipping was formerly thought very good; so that when a person was bit, he took a trip to Gravesend, which is the nearest point where the water contains a large portion of saline ingredients.<sup>a</sup> Any thing may do good which will fortify the mind; and the disease may, by that means, be more or less opposed.

*Genista Tinctoria*.—Dr. Marochetti published a pamphlet, a few years ago, in which he asserts that if the disease will appear, pustules form under the tongue after the bite; and if these pustules be abraded by a needle, and the mouth be washed with a decoction of "*genista tinctoria*" ("*butcher's broom*"), and it be taken internally, the disease is prevented. Others have, subsequently to the appearance of this publication, made a point of attending to this circumstance; but they have found no pustules, even in cases where the disease came on; and, though the *genista tinctoria* was fairly tried, the disease nevertheless made its appearance.

*Venesection*.—Venesection has been strongly recommended, on account of its supposed efficacy in some Indian cases; but it is doubtful whether it is serviceable. It was fairly tried by Dr. Rutherford, many years ago; and also by Dr. Parry. I employed it in one case; and I fancy I sent the patient out of the world, some hours sooner than she would otherwise have gone. As the blood flowed, the pulse became weaker, and the disease much more intense; and the patient died in a very short time. In Mr. Godrich's case, to which I have before alluded,<sup>b</sup> the patient was an old man; and was bled to the amount of one hundred and fifty, or one hundred and sixty ounces. No relief was afforded; he became worse and worse, and died in twenty-seven hours from the period of the attack. Magendie and Dupuytren have employed venesection, and failed. M. Breschet also says, that the more he bled his patients, the more quickly they seemed to die. I am speaking of a *rational* degree of bleeding; and it certainly does harm.

*Emetics*.—In some cases published by Dr. Satterley, it is said that an emetic proved useful. All medicines, however, have been found useful in the hands of some.

*Narcotics*.—All narcotics—opium, belladonna, nux vomica, and prussic acid—have failed. Opium injected into the veins, has seemed to give no sort of relief; and musk also has been given without any real benefit.<sup>c</sup> I was told of a case where prussic acid was given, to a very considerable amount; and yet no benefit whatever arose from it.

*Chlorides*.—The chlorides and muriatic acid have also failed. I should tire if I were to enumerate all the drugs that have been recommended in this disease, and have failed. Every article that ever was swallowed, in the way of physic, has been given without any benefit.

<sup>a</sup> See Page 651.

<sup>b</sup> See Page 644.

<sup>c</sup> The Tonquin remedy is musk and cinnabar; the Carnatic or Mysore Pill contains arsenic; the Russian remedy is water-plantain.—*Dr. Fletcher*.

*Guaco*.—I made a fair trial of a vegetable matter (guaco), which was said to cure the disease to a certainty; and Dr. Roots also made a fair trial with it; and the patient was better. Now and then, however, there are irregularities in the course of the disease; and whether the improvement was ascribable to the medicine, I cannot tell; but I should think not; for the patient died at the usual time. Some have recommended a whirling machine.

*Submersion*.—Van Helmont used to recommend putting the patient under water, and keeping him there till he was nearly drowned;<sup>a</sup> but I believe nothing will do good when the disease is formed; and I doubt whether much good can be done, even in the way of prevention.

*Transfusion of Warm Water*.—[Injection of warm water into the veins has been tried by Magendie;—from his having observed nervous debility produced in animals which had been subjected to it; and that the fluid parts of the blood were diminished by the impossibility of taking fluids, and the great cutaneous and pulmonary transpiration. A pint of water, heated to 30° (Réaumur), was injected into the arm of a man labouring under advanced and violent hydrophobia. Immediately after the operation, the patient became tranquil; and the pulse fell, in twenty minutes, from 150 to 80. The spasms ceased, and the individual drank a glass of water without difficulty. He continued to improve until the fifth day; when swellings and acute pains in the wrists, knees, and elbows, appeared; and an abscess formed in the leg;—occasioned by the broken points of two lancets, which remained in the foot, from former unsuccessful efforts to bleed. He died on the ninth day. The swollen joints were found filled with pus; and, it is probable, these secondary purulent deposits were the cause of death. Dr. Pearson recommended the injection of small quantities of warm water, impregnated with narcotic substances, into the veins,—in order to relieve the spasms which prevent deglutition, followed up by cathartics, antispasmodics, the mineral and vegetable tonics, and sponging the body with cold water and vinegar.

In the midst of so many remedies which have been lauded by partisans, and in turn found to be useless—with a knowledge that the most powerful drugs are apparently inert—overwhelmed with the sad conviction that the learning and talents of the most experienced and energetic physicians have utterly failed in arresting the progress of this dreadful malady, the practitioner, when called upon to act, must still respond to the awful question—"What is to be done?" It is in such a situation only that he can experience the benefit of having studied the whole train of nervous diseases; of being able to detect and appreciate the analogies and dissimilarities which exist between each respectively; and of having deduced from the whole such general principles, as will enable him to act conscientiously in every case, as far as the present state of the art will permit. In hydrophobia, therefore, as in tetanus, and several other nervous disorders, no exclusive line of treatment should be followed. If the patient exhibit signs of plethora, be strong, of a vigorous constitution, and there be symptoms of increased vascular excitement, venesection, cupping, or the application of leeches to the occiput or back of the neck, and antiphlogistic remedies, should be actively employed;—so as to make an impression upon the nervous system. But if there be evidence of anæmia, and general depression of the vital powers, stimulants and tonics are indicated, and should be used energetically. With a view of overcoming the spasms, the tobacco enema, or cold affusion, may be had recourse to according to circumstances; and the same kind of treatment as has been recommended for acute tetanus,<sup>b</sup> should be persevered in.<sup>c</sup>]

<sup>a</sup> He kept his patients under water, till the psalm "Miserere" [the fifty-first; containing nineteen verses] was sung; and, in one case, a poor girl was drowned.—*Dr. Fletcher*.

<sup>b</sup> See Page 633.

<sup>c</sup> "Library of Medicine;" Volume 2; Page 261.

## CHAPTER XIV.

## NEURALGIA.

*Definition.*—The disease of which I spoke last (hydrophobia), is characterized by morbid sensibility; and the disease of which I shall now speak, is also characterized by morbid sensibility. It is called “*tic douloureux*,” or “*neuralgia*,”—violent pain of the nerves. It is said to be called “*tic douloureux*” (which is a very odd appellation) because it resembles the sudden sharp pain arising from the bite of an insect; or because the horse bites the manger, when (as is supposed) he labours under it. The word “*neuralgia*” is very appropriate; but the word “*tic*” is one that I do not approve. It signifies a sudden catching or convulsive motion,—such as is noticed in the face or other parts of some persons; and is (as it were) a local chorea. Persons with such catchings, experience no pain; but when twitchings occur in neuralgia, they are attended by pain; and, therefore, to their name “*tic*” in this disease “*douloureux*” was added. As the disease was first noticed and distinguished on the face,—where there is an abundance of small muscles, and consequently twitchings usually attend it,—the twitchings usually attracted as much attention as the pain; and the disease obtained its designation from both symptoms.

*Symptoms.*—The disease is marked by a violent, stabbing, plunging pain, increased (or even brought on, when it does not exist) by the slightest touch of the skin. When it is present, it is increased by the least touch; but very firm pressure, I know, will relieve it. It is increased, too, when present, by blowing on the skin, or by the shaking of the room; and is then exactly like an electric shock. Sometimes, between the shooting pains, there is constant aching; and sometimes the part feels painfully benumbed. I have known the neighbouring parts, which were not in pain, benumbed. There is generally no swelling or redness. There may be; but it is not essential to the complaint. *Tic douloureux* generally takes place in the course of some well known nerve; and hence the disease is now more appropriately called “*neuralgia*,”—“*nerve-ache*.” Sometimes the pain does not follow the course of a nerve; but still we must consider it according to general rules. Sometimes it is not an aching of a nerve, but the whole of a part is affected together; so that the disease will exist in the breast, in the heart, or in the pericardium; and once I saw it in the loins;—apparently not following the course of any nerve, but affecting various nerves in the mass. If the nerve affected have small muscles in the neighbourhood, they are generally twitched; so that, when a patient has the disease in the face, we see the side of the face catching every moment. From these circumstances some have called the disease “*neuralgia spasmodica*,” but, I think, most improperly; because they are only incidental, and the severest neuralgia may occur without them. If the disease be dreadfully severe, as sometimes it is, then we have convulsions of the large muscles.

*Parts liable to it.*—When it is a distinct nerve that is affected, it is (more frequently than not) the supra-orbital, the infra-orbital, or the “*pes anserinus*,” and next to these the inferior maxillary.<sup>a</sup> When it is situated in these parts, there is a twitching; because the muscles of the face are small; and from the disease occurring in the neighbourhood of glands, there is commonly, in these cases, a great flow of tears or of saliva. Some doubt that it is ever felt in the “*portio dura*,” others declare they have known it in that nerve. A patient of mine in St. Thomas’s Hospital, complained of it not only in the cheek, but in the course of the “*portio*

<sup>a</sup> Neuralgia of the second division (“superior maxillary”) of the fifth pair of nerves (“trigemini”), is distinguished from disease of the antrum, by its not being attended with fever, by its following the course of the nerve, by its wanting three of the four signs of inflammation (redness, heat, and swelling), &c.—*Dr. Fletcher*.

dura,"—from the stylo-mastoid foramen. I do not see why the disease should be confined to nerves of sensation. Two, or even all the three branches of the fifth pair are sometimes affected; and the pain may extend even to the other side of the face. I have known it extend down the neck to the shoulder, and along the inside of the arm, to the ends of all the fingers and the thumb. Various nerves of the legs, arms, fingers, and toes, are occasionally the seat of the disease; and an intercostal, a lumbar, and even the spermatic nerve has been attacked. The pain may be confined to one nerve, or to it and its branches; may extend to other nerves in the neighbourhood, or at a distance; or may affect nerves distant from each other, simultaneously or successively; and change its seat backwards and forwards. The pain does not always shoot in the course of the nerve; but frequently in the opposite direction. It may not shoot from a nerve through all the twigs, but only through some.

*Progress.*—The disease comes on in paroxysms, and the pain is dreadful; so that, occasionally, it brings on delirium. After a time it will, in some instances, cease spontaneously, without our knowing why; and, in other cases, it will produce great emaciation, and end in insanity, or some other disease of the nervous system.

In hysterical females, portions of the surface occasionally become exquisitely tender; so that the least pressure with the extremity of the finger, such as would not occasion pain were the peritonæum or viscera inflamed,—even the sudden falling of the bed-clothes upon it, causes anguish. The surface of the front of the body is most frequently affected, sometimes only of the abdomen, sometimes only of the chest; sometimes portions of the back only suffer, particularly at the spine; and sometimes nearly the whole surface of both the trunk and extremities. As no pain is felt while the part is not compressed, perhaps this condition ought not to be called "neuralgia." But the absence of heat, swelling, redness, and of all signs of internal no less than of external inflammation, and of structural affection and serious disease, the perfect inutility of all the remedies of inflammation, the power of the remedies of pure nervous affection and neuralgia, prove it to be a morbid sensibility of the nerves of touch, and perhaps make it merit the epithet *neuralgic*. Cases of this description are occasionally mistaken for chronic peritonitis, and other inflammatory diseases; and, when the tenderness is felt in the course of the spine, it is too often set down as a mark of disease of the spine or its ligaments, or perhaps the whole case is referred to an affection of that portion of the spinal cord; while the morbid sensibility of the spot is merely one of the number of symptoms. I saw this tenderness in a *hysterical* and neuralgic middle-aged man who had been exposed to malaria.

The nature of neuralgic affections may be evident during life, and immediately, or not till after a lapse of time; may become evident after death only; or may never be discovered. Inflammatory conditions of the nerves and structural changes, as well as mechanical causes of irritation, may be detected during life, if the seat of these conditions is within the reach of observation: and symptoms may be induced which clearly point out inflammation or structural change, even should these be beyond our observation.

*History.*—This disease is said to have been well described, first of all, in 1756, by a surgeon named André; who lived in London, and who wrote on diseases of the urethra. It is a strange place in which to look for an account of neuralgia. Dr. Fothergill wrote upon it, in the fifth volume of the "Medical Observations and Inquiries," published in 1776. He tells us he saw fourteen instances of it. I have not seen so many. He observed it oftener in women; but this greater frequency is not a general fact. He never noticed it in persons much under forty years of age; and this observation, I believe, is confirmed. It is rare in children; yet Continental writers record cases of it in subjects only seven and nine years old. It is a disease which (I suppose) has always existed; but, like true hydrophobia, it has not been well described till modern times.

*Morbid Appearances.*—After death nothing morbid has been found. Sir Charles

Bell and Dr. Magendie both say, that they have examined neuralgic nerves, and found no morbid appearance; but, by the long continuance of the pain, the neurilema (the covering of the nerve) becomes thicker. The irritation has occasionally produced a tumour during life. From the great thickening of the surrounding parts, the veins around the nerves have sometimes been found varicose. Andral, the most recent writer on this subject, says that in acute and chronic sciatica, which is a kind of neuralgia, he never but once found any alteration of the nerve; and, in that one case, the nerve was merely a little redder than usual;—it having been injected. He says, that in a woman who had constant pain at the back of the neck, on the left side, he found nothing either in the trunks or branches of the brachial plexus. In the nerves, in a case where rheumatic pain existed at the moment of death, he found nothing wrong. The true nature of the disease, therefore, is very often a mystery.

When a portion of a nerve has been seen of an uniform dark-red colour after death; when a portion has been found diseased and enveloped in gangrenous cellular tissue; or about double its natural size, of a violet-red colour, and strewed with ecchymoses of the size of pins' heads; or a serous, bloody, or purulent effusion has been discovered among its fibres; or nerves have been found hypertrophied and connected with fungous ulcers; when a nerve has been bruised, lacerated, or half divided;—pain of greater or less intensity had been felt in the nerve or the parts upon which it is distributed.<sup>a</sup> Cotugno, Cirillo, Chaussier, Bichat, &c., have seen similar appearances after neuralgia. In some cases of disease of the brain or spinal marrow, even where paralysis is produced, pain is felt at a distance; the paralyzed parts sometimes ache severely in hemiplegia. In epilepsy and hysteria, pain is sometimes felt in the course of nerves. A portion of the pain in structural diseases of all organs, may occasionally occur in the branches and twigs of the nerves irritated by it.

*Causes.*—Neuralgia certainly arises, in many cases, from cold; and in some it certainly arises from mechanical irritation of the nerve; such as is occasioned by the stumps of old teeth, or by an exostosis. Many cases have occurred, in which the bones of the cranium have been found in a state of exostosis, or carious, when the disease appeared; but this is not by any means necessary.

To show that in some cases of neuralgia the cause becomes obvious after a time only, we may state that Dr. Abercrombie quotes one case of exquisite neuralgia of the face, that ceased on the removal of a piece of china which had been there fourteen years; and another, of ten years' duration, that ceased on the extraction of a tooth. Sir Henry Hallford mentions the case of a lady who laboured under violent *tic douloureux*, till an apparently sound tooth was extracted,—on account of the attacks being frequently preceded by uneasiness in it; and that a large exostosis was found at its root. He relates the case of a nobleman, who was liberated from the disease by the exfoliation of a portion of bone from the "*antrum maxillare*." To ascribe neuralgia, however, to these causes, in most cases, is very unpathological.

The disease frequently occurs, when we cannot explain it at all; and after death nothing has been found. Dr. Macculloch thinks that it arises from malaria;<sup>b</sup> but then he ascribes almost every thing to malaria. I have no doubt he is quite right in a great deal of what he says; but still he ascribes too much to malaria. He considers, that almost every case of toothache arises from that source. Dr. Macculloch appears (to all but himself) to ride his hobby a little too much. Errors have been committed on the other hand; and teeth have been pulled out, where the pain did not arise from the teeth. I have seen cases, where a person has lost almost every tooth; and has then been cured by quinine. However, it is possible that the nerve or the neurilema, one or both of them, may be inflamed; and, if that be the case, we must expect violent pain.<sup>c</sup>

<sup>a</sup> See Abercrombie's "*Researches on Diseases of the Brain and Spinal Cord*."

<sup>b</sup> See Pages 253 and 264.

<sup>c</sup> Parry attributes neuralgia to inflammation of the neurilema; but it comes and goes suddenly; is relieved, not by bleeding, but by opiates; is not increased by firm pressure; wants

*Rheumatic Neuralgia.*—Nerves also frequently suffer pain from rheumatism. There is decidedly a rheumatic neuralgia. The exquisite neuralgia, described as *tic douloureux*,<sup>a</sup> may arise from those vicissitudes of temperature that occasion rheumatism, and may be rheumatic. But pain, not of that description, though perhaps very acute, perhaps dull and aching (as is usual in rheumatism), is every day witnessed in the situation of nerves, in persons who have rheumatism in those situations, and who have been exposed to cold, or perhaps cold and wet; and it yields as readily to the treatment of rheumatism, as the ordinary rheumatism of other parts. The neurilema, which is a fibrous membrane, is probably still more affected than the nerve; since rheumatism is chiefly a disease of the fibrous membranes.

*Symptoms.*—In rheumatic neuralgia we observe all the varieties of suffering occasioned in other parts by rheumatism: sometimes acute pain, with tenderness, heat and even throbbing, and aggravation of the pain by heat; sometimes dull aching only; sometimes pain on motion, pressure, or other modes of mechanical irritation; sometimes remittent, intermittent, or even periodical, pain. The pain is sometimes exquisite and sudden, assuming the character of *tic douloureux*; which, we may remark, not only when rheumatic, but sometimes when not apparently so, may assume a periodical type. It is the clear situation of the pain in a nerve, and not the character of the pain, when it is not like the pain called "*tic douloureux*," that justifies us in rheumatism to pronounce it neuralgic.

The nerves chiefly attacked by rheumatism, are the sciatic and the branches of the fifth. It is very frequently inflammatory; so that the surface is tender, hot, swollen, and even red. Sometimes no marks of inflammation are discoverable, and warmth and other stimuli relieve. In the case of the face especially, (one side only of which is usually affected, and perhaps not only the nerves, but some of the surrounding parts,) there is a great tendency to periodical intermission, and the paroxysms usually occur in the evening.

*Treatment.*—When inflammation is obvious or presumable, whether rheumatic or not, local bleeding, mercury, colchicum, and the whole antiphlogistic plan, general and local, are appropriate. Should these not succeed soon, anodynes may be added; and the pain may, from an inflammatory commencement, degenerate into pain without inflammation, and demand at last solely the treatment of another form of the disease.

*Remedies for Rheumatic Neuralgia.*—When rheumatic and yet not inflammatory, the remedies of this form of rheumatism in other parts are required;—stimulants internal and external, tonics, mercury, and all modes of counter-irritation.

Coldness indicates stimulants. Among internal stimulants, besides generous diet, the ammoniated tincture of guaiacum is one of the best. It should be exhibited in such quantity and frequency as to keep the patient comfortably warm. A dose of half a drachm may be sufficient, or six drachms may be required; and a frequency of three times in the twenty-four hours may be sufficient, or the dose may require repetition every two hours; and in general both may be diminished after the remedy has been continued for some time; because it stimulates more and more, and its effect lasts longer. When there is debility, and especially paleness, iron in full quantities operates in the most salutary manner; much more so than quinine.<sup>b</sup> The hot-bath (of water or vapour,) the douche, electricity, blisters, moxas, sinapisms, tartarized antimony, croton oil, and acupuncture, frequently

three of the signs of inflammation; is not attended by fever; and does not go on to the terminations of inflammation; while, on the other hand, inflammation of the neurilema may be artificially produced, without giving rise to neuralgia. Monro looks on the twitchings of the muscles as the *cause* of the neuralgia. His opinion was favoured by a case in Guy's Hospital; in which the ointment of white lead was rubbed over the affected parts for months. It palsied the muscles, and cured the pain. Armstrong thinks it is a partial disease of the brain;—displaying itself in particular parts of the nervous system. His remedy is calomel.

—*Dr. Fletcher.*

<sup>a</sup> See Page 652.

<sup>b</sup> See Note to Page 657.

cure, if combined with all other appropriate means. Mercury carried to ptyalism frequently cures; provided the strength will bear it, and the rest of the treatment is well conducted. Even the cold shower-bath, or cold douche, if followed by good friction, will cure. A warm temperature of the atmosphere around the patient, and warm clothing, may be indispensable. Anodyne narcotics may be absolutely necessary; and the salts of morphia, stramonium, and belladonna, carried to a due extent, are by far the best, and sometimes alone will cure.

*Removal of Decayed Teeth.*—If there be an obvious exciting cause, it should (of course) be removed. If carious stumps in the gums produce it, they should be taken away: but when we consider how large a number of people have this cause of irritation, without any such disease being produced, one is more inclined to trust to the general remedies, than even to the removal of the stumps; for I know that after they have once excited the disease, or have existed with it, the disease will continue after they are removed; and though it would be but common sense to get rid of an obvious cause, yet the sulphate of quinine will cure many cases, notwithstanding the old stumps are allowed to remain.

*Sesquioxide of Iron.*—Should no structural or mechanical cause, and no inflammation be discoverable, and should the disease be of the exquisite character, then iron is the best remedy.

The usual doses of the sesquioxide of iron are, I believe, from fifteen to thirty grains; and these are given two or three times a day. Some few practitioners, I know, exhibit (occasionally) a drachm at a dose; but they consider this a large quantity; and Dr. Hutchinson—who has written upon the virtues of the medicine in neuralgia, and probably employed it more than most others—tells us, that the greatest quantity he has ever found necessary, is ninety grains in the twenty-four hours. His mode of expression leads to the supposition, that this is the largest quantity he has ever given. Mr. Carmichael has employed it as extensively as Dr. Hutchinson; and appears—from the narrations in his work upon the efficacy of iron in cancer—to have generally given less than a drachm in the twenty-four hours; and once only so much as four scruples. But I have ascertained, by very numerous trials, that, when the use of the medicine is proper, it may be given in far larger quantities; that two, three, and four drachms may be given every six, nay, even four hours; that this dose of half an ounce may be at once commenced with; and does not require, in order that it may be borne, to be reached by slow degrees; and that it may be continued many weeks, without the slightest inconvenience.

It had, for many years, been my custom to prescribe the medicine in drachm-doses; but having several cases in which its exhibition appeared proper, and never having observed any sensible effect from it, I began to think that a drachm was probably not the utmost quantity which the stomach would bear; and resolved to ascertain, by cautious augmentations of the doses, how much might be taken. It soon became evident, that there was no occasion for timidity; and my uniform experience, in nearly a hundred cases, enables me to present the results just stated. When the medicine is proper, I believe there is no limit to the quantity which may be taken; except the unwillingness of the patient to swallow it, and the inability of the stomach to manage so heavy a mass. Neither headache, thirst, heat, foulness of tongue, griping, nor constipation has occurred,<sup>a</sup> nor been increased if already present. Nay, pain and heat of the head, and giddiness existed already in some cases, and ceased during its employment.<sup>b</sup> I am enabled to say, that these quantities are ordinarily borne, (exactly as is the case with antimonial powder,) not because the operation of the medicine is resisted by an unnatural condition of the

<sup>a</sup> I wish not to assert, that such inconveniences will never occur; but the absence of them in all my trials justifies me in believing, that they will not prove common occurrences, with even half-ounce doses. Many practitioners are no longer deterred from giving iron by headache, foulness of tongue, &c., if other circumstances indicate its employment. I believe, that when it excites and disturbs, this arises from a peculiar susceptibility to its influence; unless, of course, the system is already in a highly excitable state.

<sup>b</sup> See Page 625.

system, not because the quantity is gradually reached, and not because the article is bad. The article was procured from a variety of druggists,—from many of the most respectable houses in London; and was in fact, in several examples, known to be a genuine article, prepared according to the letter of the Pharmacopœia.<sup>a</sup>

Whether there is any advantage in these very large doses, I cannot say. A drachm-dose may perhaps be as useful as one of half an ounce. Even when (as in many cases) large doses effected all the good desired, after all the small ones had failed; it may be urged, that not the *increased quantity* but the *continuance* of the remedy produced the effect; and the question can be decided only by a comparison of cases, similar in every respect, treated one half by common and the other by large doses. Reasoning analogically, one would conceive that large quantities must be more serviceable. Cinchona, for instance, will cure an ague, in doses of a drachm, given every two hours; when two or three tablespoonfuls of the decoction three times a day, or even a drachm of the substance given not more frequently, will altogether fail.<sup>b</sup> We are accustomed to increase the doses of all medicines, for the purpose of increasing the effect. In the very example of sesquioxide of iron, practitioners sometimes prescribe what they consider a small dose, sometimes what they consider a large one;—according to the force which they judge necessary to bring up against the disease; and they increase the quantity as the disease proves obstinate. Now, since it appears that the dose of this medicine has a much wider range than has been thought, and that the terms “*large*” and “*small*” must relate to quantities different from those to which they have been hitherto applied, the same habit of practice would incline us to these large doses in obstinate cases; unless such comparative observations as have been just alluded to, prove them to be nowise superior to what have hitherto been considered large. It may be worth while, too, here to quote a passage from Cullen:—“We are persuaded, that the good effects of the preparations of iron have often been missed, by their being given in too small doses. The saline preparations, in large doses, are ready to irritate the stomach; and—both on this account, and on some other considerations—it may always be proper to begin with small doses, and to increase them by degrees; but we have often found, that no great benefit is to be obtained, but when large quantities—either by the *size* of the doses, or by the *continuance* of them—have been thrown in.” I may remark, that Sydenham’s favourite form of iron was the filings; and that Cullen says—“We have found the simple rust as effectual as any other preparation; and we have always found the stomach bear it better.” It is right, however, while quoting Cullen, to mention that he also says:—“We have been informed of its being given to the quantity of six drachms in one day; but we have hardly found any stomach that would bear the third of that quantity without sickness.” The apparent variance of his experience from mine, is easily explained. He employed the *rust* of iron. Such only was the “carbonate” of the Edinburgh and also of the London Pharmacopœia, when he published his “Materia Medica.” My observations relate, of course, to the present preparation of the London Pharmacopœia;—procured by *precipitation*, and therefore an impalpable powder. The grittiness of the rust would soon turn the stomach of any one, if administered in large quantities. I may state, from abundant experience, that a scruple of the sulphate of iron, made into pills with the extract of gentian, is borne just as well as half an ounce of the sesquioxide; and that every observation that I have made respecting this dose of the latter, applies to that dose of the former. I have occasionally given more, and even in solution, without sensible effect.<sup>c</sup>

<sup>a</sup> If the articles used by me were all proved to be bad, the importance of my facts would remain little diminished; because the variety and respectability of the houses at which the medicine was purchased, show that the facts, if not true of genuine sesquioxide of iron, are true of the sesquioxide now in common use.

<sup>b</sup> See Page 273.

<sup>c</sup> See Dr. Elliotson’s paper on the “Medical Properties of the Subcarbonate of Iron;” published in the “Medico-Chirurgical Transactions,” Volume 13, Page 232. A few supplementary observations on the subject, will be found at Page 466 of the same volume.

*Quinina, &c.*—Quinina, arsenic, belladonna, stramonium, and colchicum, are said sometimes to cure this exquisite form. The want of attention to the stomach and bowels, and of the observance of good habits, will aggravate it. Relief is said to be obtained occasionally by the application of steam to the part, and sometimes by ice. The application of the strongest narcotics, and all irritants and escharotics, as well as the actual cautery, have occasionally done good.

*Division of the Nerve.*—When all has failed, the division of the nerve, or the removal of the part, if possible, may be proposed;—provided no cause in another part is obvious, and provided the pain is invariably limited to one part. Galen was acquainted with the division of the nerve as a remedy in the disease; but a royal French surgeon-maréchal appears to have been the first who performed the operation. Unfortunately it very rarely cures. One portion of the divided nerve suffers again, or the disease reappears in some other part. Too often there has not been even temporary relief. Yet amputation of the finger or thumb, in which the disease was seated, has succeeded, when the cause of the affection was local.

A case is mentioned by Mr. Wardrop, in the eighth volume of the "*Medico-Chirurgical Transactions*,"<sup>a</sup> where the pain occurred in the nerve of one of the fingers, and where nothing short of amputation succeeded; but that succeeded perfectly. There is a case mentioned in the fourth volume of the same *Transactions*,<sup>b</sup> in which amputation also proved successful.<sup>c</sup> But even where amputation has been resorted to, the disease has sometimes reappeared in other parts.

<sup>a</sup> Page 246.

<sup>b</sup> Page 50.

<sup>c</sup> The case is contained in a letter from Mr. Alexander Denmark, Surgeon to Hasler Hospital, to Mr. H. Leigh Thomas. It is entitled—"An Example of Symptoms resembling Tic Douloureux; produced by a wound in the Radial Nerve;" and is as follows:—"Henry Croft, a healthy young man, belonging to the fifty-second regiment, was wounded on the night of the sixth of April, 1812, at the storming of Badajoz. A musket-ball entered the 'triceps extensor cubiti,' about an inch and a half above the inner condyle of the 'os humeri;' and grazing the inside of that bone, passed obliquely downwards through the 'brachialis internus,' and out anteriorly near the bend of the arm. The wound soon healed, and without manifesting any particular morbid symptoms during the cure. On his admission into this hospital, I found him labouring under excessive pain, which the largest opiates could not assuage, with almost constant watching. The little sleep he had, (if it could be called such,) was disturbed by frightful dreams and starting. I always found him with the forearm bent, and in the supine posture, supported by the firm grasp of the other hand; the wrist also bent;—being unable to move it into any other position, by the voluntary exertion of its own muscles. He could suffer me to extend the hand; but with increased pain; and it always, on the removal of the extending power, fell into its former bent situation. The act of pronation he could also suffer me to perform; but, in like manner, with increase of pain. A small tumour could be felt in the site of the wound, on the anterior part of the arm, which he could not bear to be touched without evincing additional torture. He described the sensation of pain as beginning at the extremities of the thumb and all the fingers, except the little one, and extending up the arm to the part wounded. It was of a burning nature, he said; and so violent, as to cause a continual perspiration from his face. He had an excoriation on the palm of the hand, from which exuded an ichorous discharge. The cause of this he ascribed to a shell rolling over it. His agonies, he observed, were insufferable;—depriving him of sleep, and the enjoyment of his food, for which he had sometimes an appetite. He declared himself incapable of enduring it longer without some relief; and earnestly requested the removal of the arm. Before proceeding to any operation, I recommended him to try the effects of the warm and vapour-baths, anodyne embrocations, &c.; but from none of these he experienced any alleviation of his sufferings.

"The symptoms were sufficiently clear, I conceived, to lead to a correct prognosis. The part wounded, the nature of the pain, and its course from the fingers, with the exception of the little one, indicated the affection to be in the radial nerve. The increased pain attendant on the act of pronation, further corroborated that supposition;—from the pressure of the 'pronator teres' upon the nerve, in its passage through that muscle. The man said he had profuse bleeding after receiving the wound; yet I found the pulsation of the radial artery to be as strong as in the other arm. It was difficult to suppose the radial nerve wounded, and the humeral artery to escape; such, however, proved to be the case.

"I proposed to my patient the possibility of saving the limb, and relieving the pain, by cutting down upon the nerve, and removing a part of it, above the wound; which he willingly consented to; but observed, that he would rather have the arm amputated at once, than run the risk of a second operation. In a consultation which I held with my colleagues upon this case, when we considered the chance of failure, together with the injured state of the arm, and contracted elbow-joint, we determined on the propriety of amputation. I im-

*Neuralgia arising from Malaria.*—When neuralgia arises from malaria, whether ague has also been produced or not, quinia and arsenic, long continued in the largest and most frequent repeated doses that can be borne without the least inconvenience, are the best remedies; and when it is periodical or intermittent, without evident connection with malaria, they are all excellent. But sometimes a full dose of extract of stramonium or belladonna, repeated every hour or two, from just before the attack is expected to the termination of every paroxysm, succeeds better.<sup>a</sup>

## CHAPTER XV.

### PARALYSIS.

THE next disease which I shall notice, is one which very often follows apoplexy; and is the result of that state which, in the first instance, is apoplectic. I refer to paralysis.<sup>b</sup>

*Definition.*—It may be defined to be a loss or diminution of sense, or of motion, or of both; independent of any stiffness of the part, or of inflammation, or any mechanical impediment; but dependent entirely upon the condition of its nerves, or some other part of the nervous system. This disease frequently begins with sopor; or even with coma, and downright apoplexy. If it begin with a great degree of heaviness, it is called “sopor” (“sleepiness.”)

*Varieties.*—It is usually divided into three varieties:—“hemiplegia,” affecting one-half of the body divided *vertically*; “paraplegia,” affecting one-half of the body divided *horizontally*; and “paralysis *partialis*,” affecting only one particular limb, or one particular sense. The partial paralysis may be of the eye—“amaurosis;”<sup>c</sup> of the smell,—“anosmia;”<sup>d</sup> of taste,—“ageusia;”<sup>e</sup> of the touch,—“anæsthesia;”<sup>f</sup> or of hearing,—“dysecœa.”<sup>g</sup> There is no particular name for paralysis of one leg, one arm, or one side of the face.

The disease may not only vary according to the part it affects, but it may also vary in degree; so that the person shall have no use whatever of his senses, or of a portion of his body; or he shall have a use of them, only that it is impaired. Then the paralysis may differ according as it affects sensation, or motion, or both.

mediately performed the operation, with instantaneous relief to my patient. He was discharged cured in three weeks;—having, in that time, rapidly recovered both his health and strength.

“On dissecting the arm, I traced the radial nerve through the wounded parts. It seemed to be blended with, and intimately attached to them, for the space of an inch. It had been wounded; and, at the place of the injury, was thickened to twice its natural diameter; and it seemed as if contracted in its length. This contraction, I thought, partly accounted for the bent position of the arm, and the increased pain on attempting its extension; but, on further examination, I was surprised to find, on dividing the fibres on the posterior part of the wounded nerve, that there was firmly imbedded in it, a small portion of the ball, which had been driven off by grazing the bone. This description of the injury, more fully accounts for the exquisite pain felt by the patient. The ‘os humeri’ was discoloured, where it was grazed by the ball; and the humeral artery was uninjured! The nerve was evidently thickened, both above and below the wound.

<sup>a</sup> For further details we refer to Dr. Elliotson’s paper on Neuralgia, in the third volume of the “Cyclopædia of Practical Medicine;” Page 165. A very severe case of the disease, with Dr. Elliotson’s treatment of it, and remarks upon it, will be found in the “Lancet,” No. 484; Page 322. (1832–3, Volume 1; December 8, 1832.)

<sup>b</sup> See Page 513.

<sup>c</sup> From *αμαυροσ*, to darken.

<sup>d</sup> From *αν*, without; and *ὀσφ*, to smell.

<sup>e</sup> From *αν*, without; and *γευσαι*, to taste.

<sup>f</sup> From *αν*, without; and *αισθασαι*, to feel.

<sup>g</sup> From *δυσ*, with difficulty; and *ακον*, hearing.

It is very common to see paralysis affect only sensation; this must, of course, be the case with parts which have naturally no motion. If such a part be paralyzed, it must be paralyzed in *sensation*. With respect, for instance, to the internal part of the nose, the paralysis which affects it must clearly be a paralysis of sensation; and so with respect to the internal part of the ear, and likewise of the eye. If the paralysis be within the orbit,—so that motion is affected,—it is not the fault of the eye, but of the muscles which move it; but paralysis affecting the globe itself, must be paralysis of sensation. Sometimes, however, in the *extremities* we have a loss only of sensation; but that is rare. Sometimes a person loses the sense of touch, in particular parts of the body; but it is not of frequent occurrence; for generally, where a part is endowed with both sense and motion, the part either has only motion affected, or sensation and motion together.

There is still another variety. When a part is paralyzed both as to sensation and motion, the proportion of the two is very various. Sometimes a person will be powerless entirely in a limb, or in one-half of the body; and yet he will *feel* a little, while he cannot *move* at all; and sometimes the paralysis will be so perfect in both respects, that we may pinch him as hard as we please, and he may endeavour to move as much as he will, and yet both will be in vain.

There are some still rarer varieties than these. What I have now mentioned is almost of daily occurrence; but there are some variations not so common. For example; a person will sometimes lose *sensation* on *one* side of the body, and *motion* on the *other*. He may lose *sensation* as to a *leg*, and *motion* as to an *arm*; and *vice versâ*. There is even a more minute variety than this. There will be a *perfect* loss of sense and motion in *one* limb; while in *another* limb, on the same side, the loss of either sensation or motion is *imperfect*. The patient will *feel* a little with his *arm*, although he cannot *move* it; while, in his *leg*, he can neither feel nor produce the least motion. Nay, what is still more curious, this state has sometimes alternated. The part which could not *feel*, has become *motionless*; and the part which was *motionless* has, by and by, lost *sensation*.

Sometimes, when half the body is paralyzed, the other half is in a state of great agitation, and convulsions. These are cases of rare occurrence; but they are mentioned by the most respectable authors; so that there is not the least doubt as to their truth. Occasionally there is an opposite state to the *loss* of sensation;—the senses become morbidly *acute*; so that a person is quite powerless as to the *motion* of an arm or a leg, on one side of the body; and yet he will have such a morbid acuteness of *sensation*, that the creeping of a fly along the arm, will give him great uneasiness. I have seen many persons who could not use their arm, or say if a fly lighted upon it; but occasionally there has been such a morbid degree of sensibility, that the descent of a fly upon them has been most uncomfortable.

*Morbid Sense of Temperature.*—Cases occur where there is a morbid sense as to temperature, in the paralyzed parts. Some persons whose limbs are paralyzed, cannot, in the paralyzed parts, bear the slightest breath of cold air. It has often been known to excite convulsions. But, more frequently, patients will feel parts which are only of a *moderate* temperature to be exceedingly *hot*. I have met with several cases of this description. The first of the kind which occurred to me, took place in a gentleman, who was first induced to think there was something the matter with him from what he experienced on going to the water-closet. When he took his seat, he felt one side so hot, that he thought some person in a burning fever must have been there before him. He wondered how the heat could be on one side; and he soon found that if he clapped his hand against the part, it felt hot. He tried the other side; but no such sensation was experienced. It excited his astonishment; and he soon found that, as he walked along, he shook his toe about. After a time, giddiness and hemiplegia occurred, and subsequently paraplegia of the lower extremities; of which he died. Some not only feel every thing hot, in this way; but they have a constant burning sensation, whether the parts are touched or not. This is very different from what we often see; for some persons (*many* indeed) have so little feeling, that a red hot iron has been applied to the paralyzed parts, for medical purposes;

and yet not the slightest heat has been felt. Many paralytic persons have sat near a fire, and their legs have been charred; and yet they have known nothing about it, at the moment.

I have seen many cases such as that I have just mentioned, respecting a morbid sensibility to heat; and it is a thing which has been mentioned by old, as well as by modern authors. The cases are by no means uncommon. Dr. Heberden mentions a case of hemiplegia, where there was a morbid sensibility of the sense of smell;—where the patient smelt every thing so acutely, that any strong odour gave him great pain.<sup>a</sup> He reminded one of Pope's line,—

“Die of a rose in aromatic pain.”<sup>b</sup>

This I have never seen; but I have had two or three extraordinary cases of paralysis, where persons had a morbid sensibility to cold. I made a note of one, which occurred in December, 1823. A man, aged fifty-six, had been for twelve years so sensible to cold, that he had regularly worn four flannel-waistcoats; and on his wife once putting her foot against him in bed, he had rigors; which made the bed shake, and lasted for a whole hour. Once, he said, his grand-daughter put her cold hand upon him; and he felt an icy coldness in that spot for a month. Three years and a half before I saw him, he had a fall on the back of his neck; and from that time he had been considerably worse, as to all these sensations. He had vertigo; and laboured under a loss of the power of attention. He could not fix his attention; and his spirits were much depressed. I found him thirsty and flushed, and frequently he had heat all over him; but, notwithstanding that, he always felt cold. No one else, on touching him, could discover that he was so.

I had another patient under my care in 1829;—a man forty years of age. He had a morbid sensibility to low temperatures, throughout his trunk, and along his arms, as low as his elbow; but no farther. He said that things of an ordinary temperature felt cold to him; and when he put on a calico night-shirt it felt, at first, as though it had been dipped in cold water; and the sensation remained for a quarter of an hour. The sensation of putting it on next to his skin, would have been intolerable; and therefore he was obliged to ease himself in flannel; and he kept his flannel-waistcoat on as long as it would stay. He said that hot things felt hot; but that any thing of a low temperature felt exceedingly cold.

It was owing to observations of this description, that Dr. Darwin (and perhaps others) imagined that there must be a particular set of nerves for temperature. Seeing that persons sometimes lost the sense of touch, and yet had a morbid sensibility of temperature,—sometimes feeling things very *hot*, and sometimes very *cold*,—he drew the conclusion to which I have just referred. It was analogous facts to these that led persons, ages ago, to imagine there must be a distinct set of nerves for motion and sense; and the fact has since been proved by Sir Charles Bell, and still more fully established by Magendie. A French surgeon (who published in 1780) states, that there must be distinct nerves of sense and motion; because sometimes the function of motion only was affected, and sometimes only sensation. That has been proved to be the case; but it has never been proved with regard to temperature.

*Temperature of Paralyzed Parts.*—The temperature of paralyzed parts, generally follows the temperature of the surrounding air, or of bodies placed in contact with the part affected. It is said that the temperature of the paralyzed parts, is generally below what it ought to be; but that is not a proper expression; and I think Dr. Abercrombie's statement is the most correct:—“They have lost in some degree that remarkable power, possessed by the living body in a healthy state, of preserving a medium temperature; and according to the temperature to which they have

<sup>a</sup> Though paralytic persons often find the perception of the five senses dull and confused, yet I attended one whose sense of smelling, instead of being impaired, became so exquisite, as to furnish perpetual occasions of disgust and uneasiness, and from some very ridiculous causes.—Heberden's “*Commentaries*,” Chapter 69.

<sup>b</sup> “*Essay on Man*,” Epistle 1; Section 6; Line 200.

been exposed, paralytic parts become hotter or colder than sound parts, which have been exposed to the same temperature."<sup>a</sup>

*Mode of Invasion.*—Paralysis may invade very slowly,—quite imperceptibly; or it may attack very suddenly. After it has once begun, it may extend or not; and it may proceed very slowly or speedily; and may likewise increase in intensity, or never increase at all. The patient may live many years, without any further increase. It may, therefore, take place suddenly, or very slowly; it may remain stationary, or it may cease; or, if it do not cease, it may remain stationary, or it may extend; or, on the other hand, it may become more intense. Sometimes one organ becomes affected after another.

*Sometimes Intermittent.*—Occasionally it is intermittent, and even periodical. I had long read of such cases without witnessing an instance; but at last I met with a case, which was decidedly intermittent; and, indeed, in some measure periodical. The attacks always came on about half-past ten, or eleven o'clock in the morning. They did not always occur after the same interval, though sometimes they did; but the hour at which the invasion took place, was always the same. After the lapse of many months, the disease became less; ceased to be periodical; and appeared to have more of the form of fixed paralysis.<sup>b</sup>

<sup>a</sup> "Researches on the Diseases of the Brain and Spinal Cord. By J. Abercrombie, M. D." (Third Edition; Page 276.)

<sup>b</sup> I have read of intermittent palsy; and it is mentioned by Cullen;—"paralysis *intermittens*." Now among all the patients I have ever seen, and which are between thirty and forty thousand,—including those in various public establishments and private practice,—I had never seen an instance of this description. This was a case of intermittent hemiplegia. The man was admitted into Jacob's ward [in St. Thomas's Hospital], some time ago; and I mentioned his admission at the time. I gave him no medicine; because I was desirous of seeing whether his account was true or not. I seldom gave medicine in aguish or intermittent complaints, till some one in the hospital has witnessed the occurrence of the paroxysms. He stayed here [in the hospital] three weeks, without having a paroxysm; he was, however, a very respectable man; and I did not doubt his account. He then went out of the hospital;—enjoined by me to return, if his disease reappeared. One day when I came to the hospital, some time afterwards, I found him in the courts; and he said he had been seized with paroxysm that morning, and he actually was then in a state of hemiplegia on the left side. I saw it myself. I made him walk, and he dragged his leg in a semicircular way,—as patients usually do when they are labouring under hemiplegia; and he could not raise his left arm. It began at ten o'clock; and this was the usual course of the disease. He had told me, originally, that the paroxysms came on at ten o'clock in the morning; not every day, but every third or fourth day; and never after a longer period, except on one occasion; when there was an interval of sixteen days. He had been subject to this affection for two years and a half; he was forty-eight years of age; and the paroxysm would last from three to four hours; but, although it only lasted that time, he was not perfectly clear from it the whole of the day. He never knew the paroxysms begin later than eleven o'clock; or earlier than ten; till a week before he had been admitted, when one attack came on at half past ten in the evening;—the usual *hour*, but in the *evening* instead of the *morning*. The affection was not more frequent then, than when it first began. The man looked sickly,—as if he had ague; but still more as if he had suffered from a hot climate; and it appeared, that he had been in the East and West Indies, and had a fever both at Bombay and Batavia. He had suffered from dysentery; and, when in the hospital, he had diarrhoea.

I do not doubt, that this man's disease was the effect of malaria;—that his hemiplegia was a form of ague. I will not quarrel about words. You may say it was not ague; because unattended by shivering, fever, or sweating; but I have no doubt it was as much the effect of malaria, as ague is. It was merely a variety of the same affection of the system. Supposing this to be the case, and witnessing a paroxysm myself, I now gave him the sulphate of quinine; and, as the disease was of long standing, I began with a good quantity;—five grains every six hours. This medicine very soon put a stop to the complaint, but not till I had increased the dose to ten grains, every six hours;—so that he took forty grains in the twenty-four hours. This is the dose that is often required in a quartan ague; and this was a worse form of the disease than quartan, because it occurred on the third or fourth day; and the longer the interval between the attacks, the greater is the difficulty of curing the affection, which may be considered so much the more of a chronic character. It is not a matter of wonder, therefore, that so large a quantity was required. He continued in the hospital from his admission on the thirteenth of October, till the twenty-third of December,—which was more than two months,—without any other attack whatever; and his health greatly improved. It is wrong to suppose, that malaria does nothing more than produce these particular forms of intermittent disease. It poisons the whole body; and many per-

*Coexistent with other Diseases.*—Paralysis is very frequently united with other nervous diseases; particularly with mania and epilepsy. Persons who are epileptic, frequently become paralytic at last; though perhaps, if they be adults, not till after many years have elapsed. Insane persons, too, frequently are seen to be paralytic. When recovery takes place, it is in general very slowly; but sometimes, though rarely, recovery is sudden.

*Causes.*—This disease may be induced by any thing which compresses a portion of the nervous system; which *divides* any portion of the nervous system; or by the disorganization of a portion. It is obvious, that whether a part of the nervous tract be *compressed* (so that the function cannot continue along it), or whether it be *divided* (so that the function cannot continue along it), or whether it be *disorganized*, the result must be the same. Accordingly, if a nerve be divided, the parts below are paralyzed. If the spinal marrow be divided, or completely compressed, or softened at any spot, the parts below are necessarily palsied. The compression may arise from fluid effused around, from fluid effused in the substance, from a collection of blood, or (in fact) from any thing capable of producing pressure. But sometimes the disease would appear to arise independently of compression, division, or disorganization. The nature of this state we cannot exactly ascertain; but the part is unfit for its functions. Lead will have this effect; and arsenic, together with various other poisons, will deprive a part of the power of continuing its functions:—so that paralysis takes place, without our being able to say what is the exact effect produced by these agents. Cold, likewise, will produce paralysis. If a part be exceedingly benumbed, it produces common paralysis, for a longer or shorter time afterwards.

*Its Extent depends on the Part affected.*—Although I am not aware that any difference would be discovered by the eye of an anatomist, in examining the parts, yet the higher the source of the disease, the more extensive are the effects; so that compression, division, or disorganization of the lower part of the spinal marrow, does not produce so extensive a paralysis, as the same causes acting higher up; and if the cause be within the head, (in one of the hemispheres, or one of the “*thalami nervorum opticorum*,” or one of the “*corpora striata*,”) patients generally have paralysis of the upper part of the body. The cause of hemiplegia, therefore, is in the brain. If *both* sides of the brain be compressed to an intense degree, then we have apoplexy; for apoplexy is evidently double hemiplegia. If the cause, on the other hand, be very *slight* pressure within the head, we have an exceedingly slight paralysis;—merely a little numbness at the ends of the fingers. Many persons who have a little fulness of the head, will have a numbness at the end of the fingers, and tingling; and, on losing blood, it will go off. There is every degree of paralysis, according to the pressure. If the pressure be inconsiderable, we have no more than an affection of the nerves, at the most opposite part of the brain.

sons are destroyed by it, without having ague at all;—so deadly is the poison. His health, however, regularly improved under the quinine; he became strong, his countenance was better, and altogether he found that he had received very great benefit. However, on the twenty-eighth of December, five days after his dismissal, he came to me; saying, that he had had a very slight attack that morning, and that it occurred rather later than usual,—some little time after eleven o'clock. When I saw him, at about half past one o'clock, it was nearly gone off. I increased the quantity of sulphate of quinine, to fifteen grains every six hours; and, if that be not sufficient, I shall give him more; as he is to come to me from time to time. I had a case of a person in the hospital, who was not cured of ague with less than a scruple every six hours; and therefore I shall not be surprised, if it be required in the case of this man; but I have no doubt he will be perfectly cured eventually.

This is a very interesting case;—proving that paralysis is not necessarily an *organic* affection;—and that hemiplegia does not necessarily arise from effusion, or from compression depending on an organic nature. If any compression do occur in this man, it can only be during the fit; for at other times he is perfectly well. It is entirely, I presume, an affair of function, induced by a particular poison.—*Extracted from a Clinical Lecture, delivered at St. Thomas's Hospital, by Dr. Elliotson; and published in the “London Medical Gazette,” No. 163; January 15, 1831. (Volume 7; Page 486.)*

## SECTION I.—HEMIPLEGIA.

*Symptoms.*—I shall now describe the *particular forms* of paralysis; and, in the first place, consider hemiplegia (which derives its name from *ἡμιος*, *half*; and *πλησσω*, *to strike*). In this disease, one half of the body (divided *vertically*) is paralyzed. There is generally no loss of sight, smell, taste, or hearing. Indeed, there is one case, to which I before alluded, put on record by Dr. Heberden, where an individual labouring under hemiplegia, had an extraordinary *acuteness* of smell.<sup>a</sup> But, in general, when paralysis occurs down one half the body, it is not *perfect* paralysis; in so far as the eye and ear of that side, half of the nose, and the tongue, have their senses acutely enough. This form of paralysis, very often, is united with more or less delirium and phrenitis. It frequently attacks those who are fatigued; or who labour under mania. It may be a mere hysterical affection, and soon recovered from. The *other* forms of paralysis may be hysterical; but hysteria, when accompanied by paralysis, is perhaps more frequently accompanied by hemiplegia, than by any other form.

*Most frequent on the Left Side.*—With regard to the side affected, Sir Gilbert Blane says, from some comparative observations made by him when physician at St. Thomas's Hospital, that he found *three* cases of hemiplegia on the *left* side, for *two* on the *right*. I have not myself made any comparative observations. The pulse, on the paralytic side, is smaller than on the other.

*A Sequel of Apoplexy.*—Hemiplegia is, very commonly, a sequel of apoplexy. When a fit of apoplexy is over, and paralysis is left, the form is usually hemiplegic.<sup>b</sup> Generally, when hemiplegia occurs suddenly, there is a degree of apoplexy; an imperfect apoplectic fit;—a degree of drowsiness and sleepiness. There may be no stertorous breathing; but the person generally loses himself for a time. I think hemiplegia more frequently commences in that way, than in any other; but where a person has a downright attack of fully formed apoplexy, the disease is very likely indeed to follow. Serres (to whom I formerly alluded<sup>c</sup>) says, that of one hundred cases of apoplexy which he examined, seventy-nine of them were complicated with palsy;—so frequently is apoplexy followed by palsy. Occasionally there is not only no real perfect apoplexy, but no sopor,—no loss of the individual to himself for a time;—but merely vertigo,—a little confusion; and then, to his great astonishment, the patient finds an arm or a leg palsied.

*More frequently occurs in Bed.*—An attack of this description, I think, more frequently occurs in bed, than in any other place. Many persons who lose the use of one side suddenly, and who have no decided apoplectic attack, say that it happened in bed;—that they awoke in the morning, and found themselves in this situation; or that it occurred late at night, or very early in the morning.

*May commence gradually.*—Occasionally, however, this form of the disease begins very slowly; commencing in the fingers or in the toes, and creeping up; and occasionally, where it does begin suddenly, the person first loses the use of a leg or an arm, and then (an hour, a day, or a week afterwards) he loses the other member of the affected side.

*General Effects.*—From the voluntary muscles of half the body being more or less deprived of the influence of the will, the face is usually drawn to the opposite side. From the muscles losing the influence of the nerves connected with the brain and spinal marrow, they are more or less powerless; and the muscles of the opposite side, which are in due connection with the brain, get the better of them, and master them completely; so that the face is drawn to the healthy side. The tongue, if it be drawn at all, is usually drawn to the same side;—on account of the operation of the muscles. From the impaired state of the muscles of the mouth and tongue, the person does not swallow his saliva as soon as it is formed.

<sup>a</sup> See Page 661.<sup>b</sup> See Page 513.<sup>c</sup> See Page 510.

We are always getting rid of it in health more or less insensibly; but for want of this voluntary action, it collects to a certain amount, and then runs out of the corner of the mouth; so that the patient slobbers. If the disease affect the mouth with any intensity, the voice is thick, from the affection of the muscles of the throat. The patient's utterance is altered; he "clips the king's English," as people say; and perhaps he can scarcely pronounce his words with sufficient distinctness to be understood. If the paralysis be perfect, the face and gait of the person at once show the nature of the disease, without the necessity of asking a question. The mouth is drawn to one side; the saliva runs out; the arm hangs useless; and, if the patient attempt to walk, he drags the affected limb in a sort of semicircular manner; having the ball of the great toe, for the most part, in contact with the ground.

When the disease continues for any considerable time, the limbs waste;—they become flabby to the feel, and diminish in size. The mind, too, generally suffers a little. The patient does not find his attention so good as it was before; nor his memory. His feelings are much affected; so that he is disposed to burst into tears, without any evident external cause; and he is, for the most part, very peevish. I mentioned, when speaking of tetanus, that Sir Gilbert Blane informed me of a case, which was accompanied by pleasurable twitches;<sup>a</sup> and Dr. Cook, in his work on Nervous Disease, mentions the case of a person who had been very captious; but who, after a fit of palsy, became the most good-natured person possible. The symptoms which occurred at the time of the fit, or preceded it, (such as vertigo and headache,) may continue afterwards, and may increase. There is great variety, as to the effects of sense and motion, in the affected part. Sometimes the person retains his *feelings* perfectly, but loses all powers of *motion*; and, in other cases, a person loses both; but it is a very rare thing indeed to see a loss of the sense of touch. Usually motion is impaired or destroyed; and sensation more or less so, or not at all.

*Frequently followed by Apoplexy.*—This disease, very frequently, does not follow apoplexy; but is itself followed by apoplexy.<sup>b</sup> We may easily imagine that, if the cause be in the brain, although at first it may be so inconsiderable as only to be just sufficient to produce hemiplegia, yet it may, if the morbid process go on, become more considerable; and, at last, it may be sufficient to produce apoplexy. While apoplexy sometimes leaves hemiplegia, hemiplegia is sometimes followed by apoplexy.

*Progress of Amendment.*—When the disease diminishes, I believe (for the most part) the arm mends last;—that, after the patient has begun to walk tolerably with the affected limb, his arm long remains useless at his side; and sometimes it never recovers. There is a variety in this. Some persons recover both limbs at once; but if there be any difference, it is in favour of the leg. While some persons completely recover, others do not recover at all; and while some will get worse, others will remain stationary. Some persons will live ten, or perhaps fifteen years, in the same state. Another difference occurs. They will mend up to a certain point; perhaps for a year or two; and then never advance further.

*Liable to recur.*—This is a disease which may occur again and again. Recurrences of it are frequently seen. It is a disease which I have seen, several times, in children; and, I believe, more frequently than not, they recover from it.

*Causes and Morbid Appearances.*—The cause of this particular form of paralysis is sometimes mere fulness about the head;—fulness which is often transient; and therefore the disease is transient. Frequently there is found, after death, serous effusion; and that, perhaps, in a very inconsiderable quantity, even where the paralysis is very great; and perhaps the effusion is rather the effect of the morbid cause which induces the paralysis, than the cause of the paralysis itself. Effusion, however, is often the cause of paralysis. The most frequent state of the brain which I see, (and therefore, I suppose, which other people see,) is a softened

<sup>a</sup> See Page 623.

<sup>b</sup> See Page 513.

state of some one spot. It is curious how small a portion is sometimes sufficient, when softened, to give rise to this disease. Occasionally the softening is very great;—extending over a great part of one of the hemispheres, or the “corpus callosum.” This softening, in many cases, is clearly the result of inflammation. A chronic inflammation of the brain, often precedes this softened state; and very frequently it follows an *acute* inflammation of the brain. Persons seized with acute inflammation of the brain become paralytic; and we afterwards find the brain more or less softened. Sometimes the disease will increase. The patient becomes delirious; perhaps he has epileptic fits; and the head is very hot. All the time he is delirious, he complains of great pain of the head, and, on opening the skull, we find a portion of the brain softened; and around the softened spot, and even running through it, are seen red vessels. There can be no doubt, in such a case as this, that the disease is the result of inflammation. I, as well as others, have frequently noticed, that after paralysis has begun, although there may previously have been no great affection of the head, the latter will sometimes become affected. Patients gradually complain of more and more pain; gradually have the head more and more hot; gradually become more and more delirious; and then they die. It appears as though, at first, there had only been softening enough to produce paralysis;—only enough to produce inflammation; and the latter has then gone on to a far greater extent. It is said, by Dr. Hooper and others, that when there is softness of the brain, it is analogous to the gangrene of other parts; but whether it really is the case, I do not know. A part may be softened, without there having been symptoms to lead us to conclude the existence of gangrene. There can be no question that this softening of the brain is, sometimes, not inflammatory; for it is accompanied by paleness, not only in one spot, but all around. If there be inflammation, it shows itself in a very odd way; for the part is white all around. I can suppose that the brain may be broken up, without inflammation;—just as the coats of the stomach may sometimes be found perfectly pulpy, and perfectly pale.

*Sometimes caused by a Coagulum.*—Occasionally the paralysis, in hemiplegia, has been induced by a coagulum of blood; and this coagulum may be of all sizes. When paralysis comes on in a moment, without any previous inflammation, I imagine that in general there is an effusion of blood. Apoplexy may be the result of the effusion of blood; but when the apoplexy is over,—when, I presume, that general state of congestion of the blood-vessels, which was sufficient to produce apoplexy, has gone off,—then there remains a clot, just sufficient to produce hemiplegia. The blood becomes absorbed;—sometimes leaving a cavity, and sometimes not; the parts then all become contracted together; and a cicatrix is formed. Around this spot, the brain is generally softened. I mentioned this circumstance, as taking place in apoplexy; and it also occurs in paralysis. The paralysis arises, I believe, from what remains after the clot has been absorbed. The brown, dark-coloured substance, which is sometimes taken from the brain of a hemiplegic patient, I should imagine to be the remains of blood. The blood was nearly all absorbed; but the brown softened part left behind, was quite sufficient to produce paralysis.

Dr. Abercrombie says, a cyst will form round a clot of this kind, even in a fortnight. Whether extravasated blood can be absorbed from a ventricle, if effused in any quantity, I do not know; but I should think not. In most cases of that description, the blood has lacerated the brain, and forced its way from the substance of the hemisphere, into the ventricle. Four ounces of blood have been found, after paralysis, in a cavity formed in the brain. When the brain has been softened, and has produced hemiplegia, or fatuity, or only an aberration of the mental faculties, the vessels will sometimes suddenly give way; and then there is apoplexy;—an effusion of blood suddenly taking place into the softened part. Softening is supposed, by some, to resemble “*gangrena senilis*,”—that gangrene which takes place in the toes of old people, from ossification<sup>b</sup> of the small vessels. Some will have it,

\* See Page 516.

<sup>b</sup> From “*os*, *ossis*,” a bone; and “*facio*,” to make.

that it is not the result of inflammation; but of disease of the vessels, affecting the circulation. I should imagine the truth to be, that (like most other diseases) it is the effect of different circumstances. That inflammation will soften the brain, there can be no doubt; and if the vessels be obstructed, so that the part is not nourished perfectly, then also it will become soft.

*Pressure from various Tumours.*—Pressure from an abscess, or from various tumours formed upon the surface of the brain, (whether they be encysted, carcinomatous, melanotic, or of any other kind,) may have this effect. *White* tumours, *reddish* tumours, *scrofulous* tumours, tumours of all descriptions, and hydatids, have been seen (in this disease) pressing upon the brain, in different parts. It has sometimes been occasioned by the pressure of an exostosis;—from the bone growing too much in one particular spot, so as to compress the brain. Excessive thickening of the membranes has given rise to the disease.

*The Cause is on the opposite side.*—It is a well established fact, I think, that the disease occurs on the opposite side to that in which the cause of it resides. The observation of this fact is so general,—so many persons, who have extensive opportunities of examining patients, assert that they never met with any exception to it, that I cannot but think the few exceptions on record must have been mistakes. Serres says, that he opened one hundred and seventy cases of apoplexy united with hemiplegia; and that, in all those cases, the affection was on the opposite side. He opened forty-seven cases of mere hemiplegia; and there the affection was on the opposite side; and in about one hundred and fifty cases of paralysis detailed to him, the results were the same. I never saw an exception to it; and many authors say the same. There are a few instances to the contrary on record; some of which I have looked over; and to me they are any thing but satisfactory. In some of these, there could be no doubt, other morbid appearances were found at the same time; so that, in all probability, sufficient attention was not paid to the opposite side. In general, the brain is sliced very rapidly; and morbid appearances in the brain, I know, are every day passed over. On the other hand, when the *spinal marrow* suffers compression, or any cause sufficient to induce paralysis, the disease occurs on the *same* side.

*Cause generally in the Substance of the Brain.*—The cause of hemiplegia is generally within the substance of the brain; and pressure of the brain usually produces apoplexy; so that, I conceive, we have a reason for apoplexy occurring so often first, and leaving hemiplegia behind. Apoplexy generally arises from a mere temporary fulness of the vessels of the head. It goes off; and then some injury occurs at one particular spot, and is sufficient to produce hemiplegia. Local pressure on the surface of the brain, however, may likewise produce hemiplegia; and local pressure on any part of the brain, if it be very intense, will produce apoplexy, because pressure in any one spot of the brain, if it be intense, will necessarily compress the whole.

*Loss of Verbal Memory.*—A very curious symptom, sometimes observed in hemiplegia, is a loss of verbal memory. This is quite distinct from a loss of the power of utterance. In general, persons in this disease do not speak well; because they have not full power over the voluntary muscles of articulation;<sup>a</sup> but, sometimes, if they *can* speak well, they have not a proper word in their mind; and they cannot make themselves understood. Some forget entirely the meaning of words; some forget entirely the meaning only of *names*;<sup>b</sup> and some do not forget these

<sup>a</sup> See Page 665.

<sup>b</sup> A singular instance has been related to me, of a gentleman who could not be made to understand the name of an object if it was *spoken* to him, but understood it perfectly when it was *written*. His mental faculties were so entire, that he was engaged in most extensive agricultural concerns; and he managed them with perfect correctness, by means of a remarkable contrivance. He kept before him, in the room where he transacted business, a list of the words which were most apt to occur in his intercourse with his workmen. When one of these wished to communicate with him on any subject, he first heard what the workmen had to say, but without understanding him further than simply to catch the words. He then turned to the words in his written list, and whenever they met his eye, he understood them

entirely; for the moment the proper word is mentioned, they say—"Right, thank you!" They know it directly. This affection of the mind occurs, sometimes, without any hemiplegia; and sometimes it lasts for a period, and then hemiplegia supervenes. Some have an abundance of words; but do not know their proper meaning. They distribute them about very incorrectly; so as not to express their wishes. Others have only a few words; and with these they endeavour to say every thing.

Dr. Prichard, in his work on Diseases of the Nervous System (to which I have so often referred),<sup>a</sup> mentions the case of a lady, who forgot the names of all persons; and of another who forgot the names of some things;<sup>b</sup> and who likewise forgot that she had ever been married. Dr. Currie mentions the case of a man, who forgot the Hebrew language alone, out of several with which he was acquainted.<sup>c</sup> Mr. Abernethy used to mention the case of a man who, after an injury of the head, though he knew English very well, could speak nothing but French. He had been equally acquainted with both languages; but, after the injury he had sustained, he could only speak French. He also thought he was only sixteen years of age. Dr. Rush mentions the case of a lady, who forgot her English, and spoke nothing but French for a month.

A writer on hemiplegia, named Wepfer, mentions a case of this disease, in which, after the stupor ushering it in went off, the patient recollected neither persons nor words; and when he recovered the words again, he forgot their meaning. He lost all his language;—could not utter a single word; and at last, when he could, he forgot their meaning; and he preferred Latin to his own native language, which was German. He could read any thing, a few words at a time; and he wrote both Latin and English in elegant characters; but without knowing the meaning of a word. The end of the case was, that he died apoplectic.<sup>d</sup>

Some persons, however, forget only proper names.<sup>e</sup> Sir Alexander Crichton

perfectly. These particulars I heard from his son;—a gentleman of high intelligence. Another frequent modification consists in putting one name for another, but always using the words in the same sense. An example of this also occurred in the gentleman last mentioned. He uniformly called his snuff-box a "hog'shead;" and the association which led to this appeared to be obvious. In the early part of his life, he had been in Virginia, and connected with the trade in tobacco; so that the transition from snuff to tobacco, and from tobacco to a hog'shead, seemed to be natural. Another gentleman, affected in this manner, when he wanted coals put upon his fire, always called for paper; and when he wanted paper, called for coals; and these words he always used in the same manner. In other cases, the patient seems to invent names;—using words which, to a stranger, are quite unintelligible; but he always uses them in the same sense, and his immediate attendants come to understand what he means by them.—*Dr. Abercrombie's "Inquiries concerning the Intellectual Powers;" Part 3; Section 1; Subsection 5. (Ninth Edition; Page 152.)*

<sup>a</sup> See Page 599.

<sup>b</sup> The late Dr. Gregory used to mention a lady, who, after an apoplectic attack, recovered correctly her ideas of things, but could not name them. In giving directions concerning family matters, she was quite distinct as to what she wished to be done; but could make herself understood only by going through the house, and pointing to the various articles.—*Dr. Abercrombie's "Inquiries concerning the Intellectual Powers;" Part 3; Section 1; Subsection 5. (Ninth Edition; Page 150.)*

<sup>c</sup> Dr. Beattie mentions a gentleman who, after a blow on the head, lost his knowledge of Greek; and did not appear to have lost any thing else.—*Dr. Abercrombie on the Intellectual Powers;" Part 3; Section 1; Subsection 5. (Ninth Edition; Page 155.)*

<sup>d</sup> After several weeks he began to know his friends, to remember words, to repeat "the Lord's prayer," and to read a few words of Latin, rather than German, which was his own language. When urged to read more than a few words at a time, he said that he formerly understood these things, but now did not. After some time, he began to pay more attention to what was passing around him; but, while thus making slight and gradual progress, he was (after a few months) suddenly cut off by an attack of apoplexy.—*Dr. Abercrombie's "Inquiries concerning the Intellectual Powers;" Part 3; Section 1; Subsection 5. (Ninth Edition; Page 147.)*

<sup>e</sup> A gentleman whom I attended some years ago, after recovering from an apoplectic attack, knew his friends perfectly, but could not name them. Walking one day in the street, he met a gentleman to whom he was very anxious to communicate something concerning a mutual friend. After various ineffectual attempts to make him understand whom he meant, he at last seized him by the arm, and dragged him through several streets, to the house of

mentions the case of an attorney who, in his seventieth year, married a young lady; and, being very excitable, he also every evening saw his mistress. Under all this, as a consequence, from the excitement of his brain, he was seized with vertigo and insensibility; and these symptoms were followed by a loss of memory;—so that, instead of asking for *bread*, he asked for his *boots*; and if they were brought to him, he was very angry, because he wanted something to eat; but still he kept asking for *boots* or *shoes*, instead of for *bread*. Instead of asking for a *tumbler*, he inquired for a *chamber-pot*; and when he wanted a *chamber-pot*, he asked for a *tumbler* or *dish*: and yet he was conscious he was wrong; and recognized the right words when they were spoken by others, and then pronounced them by imitation.<sup>a</sup>

Dr. Abercrombie mentions having seen a case, in which the same wrong word was always used in the same wrong way. Whenever the patient missed the name of a particular object, he applied the same incorrect word (whatever it was) to the same thing. In the "Psychological Magazine," which is quoted by Sir Alexander Crichton (in his work on Disorders of the Mind), a case is mentioned where a person, after much tiresome business, on attempting to write a receipt one morning, could not write more than the two first words. He wrote on slowly, letter after letter, in the most deliberate manner. He found that he spoke words different from what he meant. He saw that he was wrong; but he could not set himself right; but, instead of writing—"Received fifty dollars for half a year's rent," he wrote—"Received fifty dollars through the salvation of the Bible." This state lasted an hour or two, and then nothing of it remained.

I have seen two instances of this description. The one occurred in a lady, who was not hemiplegic, but who said she had a violent pain above each eye; and as long as that lasted, she could not tell the name of any thing; but when the name was mentioned, she knew it. This continued for some hours; and then the pain went off, and she knew every thing as well as before. After a short time, a second attack occurred. She had been taking digitalis. I know an instance of a medical man, who makes a dead pause, and says—"I cannot tell the word; I want to tell you what is the name of such a thing." It will occur every thirty or forty words.

Dr. Currie (formerly of Guy's Hospital) says that he knew a person who, during an attack of this description, began his words in English, and ended them in Latin. At St. Thomas's Hospital (before the time of my connection with that institution), there was a Welchman who had forgotten his native language; but, while suffering from an injury of the head, he spoke nothing but Welch.<sup>b</sup> When he recovered, he forgot it entirely; and talked only English.<sup>c</sup> Dr. Rush mentions an instance of a student who, in consequence of a fever, lost his Latin, and began to learn it again; when, one day, it suddenly returned;—just as the power over paralyzed parts of the body will occasionally do. He also mentions, that a French conness, during the excitement of fever, spoke the language of Lower Brittany, which she had learned when young.<sup>d</sup> Dr. Abercrombie (one of the most recent writers on

the gentleman of whom he was speaking, and pointed to the name-plate on the door.—Dr. Abercrombie's "Inquiries concerning the Intellectual Powers;" Part 3; Section 1; Subsection 5. (Ninth Edition; Page 150.)

<sup>a</sup> This gentleman was cured of the complaint, by large doses of valerian, and other cardiacs.—Dr. Mason Good's "Study of Medicine;" Class 4; Order 1; Genus 6; Species 1; Variety 2.

<sup>b</sup> A few years ago, a man with brain fever was taken into St. Thomas's Hospital; and, as he grew better, spoke to his attendants, but in a language they did not understand. A Welch milk-woman, going by accident into the ward, heard him, answered him, and conversed with him. It was then found, that the patient was by birth a Welchman; but had left his native land in his youth, forgotten his native dialect, and used English for the last thirty years. Yet, in consequence of this fever, he had now forgotten the English tongue, and suddenly recovered the Welch.—Dr. Mason Good's "Study of Medicine;" Class 4; Order 1; Genus 6; Species 1; Variety 2.

<sup>c</sup> Sir Asstley Cooper mentions this case, as having occurred in Guy's Hospital. It is recorded in his "Treatise on Dislocations and Fractures of the Joints (abridged). With important Additions, from the Works of the most distinguished modern Surgeons. Edited by Alexander Cooper Lee." Published by Butler, Medical Bookseller, St. Thomas's Street, Southwark. Page 536.

<sup>d</sup> A lady, mentioned by Dr. Prichard, when in a state of delirium, spoke a language which

the subject) mentions the case of an American student; who, after fever, forgot all names;<sup>a</sup> and, after learning the names, he was taught to read, and began his Latin. After a little progress, he had suddenly a strong sensation in his head. He applied his hand to it; and said, that he found all he had been learning he knew some time before.

[Dr. Rush mentions an Italian gentleman, who died of the yellow fever in New York; and who, in the beginning of his illness spoke English, in the middle of it French, but on the day of his death only Italian.

A Lutheran clergyman, of Philadelphia, informed Dr. Rush, that Germans and Swedes, of whom he had a considerable number in his congregation, when near death, always prayed in their native languages; though some of them, he was confident, had not spoken these languages for fifty or sixty years.

A case has been related to me<sup>b</sup> of a boy who, at the age of four, received a fracture of the skull, for which he underwent the operation of trepan. He was, at the time, in a state of perfect stupor; and, after his recovery, retained no recollection either of the accident or the operation. At the age of fifteen, during the delirium of a fever, he gave his mother an account of the operation, and the persons who were present at it; with a correct description of their dress, and other minute particulars. He had never been observed to allude to it before; and no means were known by which he could have acquired the circumstances which he mentioned. An eminent medical friend informs me,<sup>b</sup> that, during fever, without any delirium, he on one occasion repeated long passages from Homer, which he could not do when in health; and another friend has mentioned to me, that, in a similar situation, there were represented to his mind, in a most vivid manner, the circumstances of a journey to the Highlands, which he had performed long before;—including many minute particulars, which he had entirely forgotten. A gentleman, who was under the care of Dr. Johnston, of Kirkaldy, when in a state of slight delirium, connected with erysipelas of the head, sang with great precision some Gaelic songs. In health he had no kind of taste for music; and though in his youth he had some knowledge of the Gaelic language, he had been for many years entirely unaccustomed to it, and his knowledge of the language was supposed to be nearly or altogether lost. An ignorant servant girl, mentioned by Coleridge, during the delirium of fever, repeated passages from theological works in Latin, Greek, and Rabbinical Hebrew; which, being taken down and traced to the works from which they were derived, were found to be repeated with perfect accuracy. It turned out, that she had been servant to a clergyman,—a man of much learning and peculiar habits; who was in the practice of walking backwards and forwards, along a passage in his house which led to the kitchen, and there reading aloud his favourite authors. The late Dr. Gregory<sup>c</sup> was accustomed to mention, in his lectures, the

nobody about her understood; but which also was discovered to be Welch. None of her friends could form any conception of the manner in which she had become acquainted with that language; but (after much inquiry) it was discovered that in her childhood she had a nurse, who was a native of a district on the coast of Brittany; the dialect of which is closely analogous to Welch. The lady had at that time learnt a good deal of this dialect; but had entirely forgotten it for many years before this attack of fever.—Dr. Abercrombie's *"Inquiries concerning the Intellectual Powers,"* Part 3; Section 1; Subsection 5; Head 4. (Ninth Edition; Page 141.)

<sup>a</sup> The late Bishop of Llandaff, Dr. Watson, gives a singular case of partial amnesia in his father;—the result of an apoplectic attack. "I have heard him ask twenty times a day," says Dr. Watson,—"'What is the name of the lad that is at college?' (my elder brother); and yet he was able to repeat, without a blunder, hundreds of lines out of classic authors." Hence, there is no reason for discrediting the story of a German statesman, a Mr. Von B., related in the seventh volume of the *"Psychological Magazine,"* who, having called at a gentleman's house, the servants of which did not know him, was under the necessity of giving his name; but unfortunately at that moment, he had forgotten it; and excited no small degree of laughter, by turning round to a friend who accompanied him, and saying, with great earnestness,—"'Pray tell me who I am; for I cannot recollect!'"—Dr. Mason Good's *"Study of Medicine,"* Class 4; Order 1; Genus 6; Species 1; Variety 2.

<sup>b</sup> Dr. Abercrombie.

<sup>c</sup> See Note to Page 239.

case of a clergyman who, while labouring under a disease of the brain, spoke nothing but Hebrew; which was ascertained to be the last language he had acquired. An English lady, mentioned by Dr. Prichard, on recovering from an apoplectic attack, always spoke to her attendants in French; and had actually lost the knowledge of the English language. This continued about a month. A gentleman, whom I<sup>a</sup> attended in a state of perfect apoplexy (from which he did not recover), was frequently observed to adjust his nightcap with the utmost care, when it got into an uncomfortable state;—first pulling it down over his eyes, and then turning up the front of it, in the most exact manner. Another, whom I<sup>a</sup> saw in a state of profound apoplexy (from which he recovered), had a perfect recollection of what took place during the attack; and mentioned many things which had been said in his hearing, when he was supposed to be in a state of unconsciousness. A lady, on recovering from a similar state, said she had been asleep and dreaming.

A man, mentioned by Willis, on recovering from a putrid fever, was found to have so entirely lost his mental faculties, that he knew nobody, remembered nothing, and understood nothing. He continued in this state for two months, and then gradually recovered. Some years ago I<sup>a</sup> attended a young man who, on recovering from a tedious fever, was found to be in a state bordering upon idiotism; and this continued even after his bodily health was restored. In this state he was taken into the country; when, after several months, he gradually recovered.

Some years ago, I<sup>a</sup> saw a boy who had fallen from a wall, and struck his head against a stone which lay at the foot of it. He was carried home in a state of insensibility, from which he soon recovered, but without any recollection of the accident. He felt that his head was hurt; but he had no idea how he had received the injury. After a short time, he recollected that he had struck his head against a stone; but had no recollection how he had come to do so. After another interval, he recollected that he had been on the top of a wall, and had fallen from it, and struck against the stone; but could not remember where that wall was. After some time longer, he recovered the recollection of all the circumstances. Dr. Prichard mentions a gentleman, who suffered a severe injury by a fall from his horse, and on his recovery had no recollection of any thing of the accident, or for some time before it. A considerable time elapsed before his recollection of it began to return; and it was only as he repeatedly rode over the country where the accident had happened, that the sight of the various objects gradually recalled the circumstances of the journey in which it occurred, and the accident itself. A lady, whose case has been communicated to me,<sup>a</sup> was seized with an apoplectic attack while engaged at cards. The seizure took place on a Thursday evening. She lay in a state of stupor on Friday and Saturday; and recovered her consciousness, rather suddenly, on Sunday. The first words she then uttered were—"What is trump?" A respectable surgeon was thrown from his horse, while riding in the country; and was carried into an adjoining house, in a state of insensibility. From this he very soon recovered, described the accident distinctly, and gave minute directions with regard to his own treatment. In particular, he requested that he might be immediately bled; the bleeding was repeated, at his own desire, after two hours; and he conversed correctly, regarding his feelings, and the state of his pulse, with the medical man who visited him. In the evening, he was so much recovered as to be able to be removed to his own house; and a medical friend accompanied him in the carriage. As they drew near home, the latter made some observation, respecting precautions calculated to prevent unnecessary alarm to the wife and family of the patient; when, to his astonishment, he discovered that his friend had lost all idea of having either wife or children. This continued during the following day; and it was only on the third day, and after further bleeding, that the circumstances of his past life began to recur to his mind.

A young clergyman, when on the point of being married, suffered an injury of the head, by which his understanding was entirely and permanently deranged.

<sup>a</sup> Dr. Abercrombie.

He lived in this condition to eighty; and, to the last, talked of nothing but his approaching wedding, and expressed impatience for the arrival of the happy day.\*]

[Many persons can catch hold of an entire song, an entire sermon, or a series of speeches in parliament; and can recite them almost, if not altogether, verbatim immediately afterwards; but who lose all recollection of them in a day or two: while there are others, who are obliged to pause over the subject submitted to them, or have it repeated several times before they can get it by heart; yet who, when they have once fixed it in the memory, retain it as long as they live. Mr. W. Woodfall, the celebrated reporter of the parliamentary debates, was an instance of the former of these talents, with regard to his powers of apprehension; the well known Jedediah Buxton was an example of the latter: though it may be mentioned, that Mr. Woodfall retained with as much ease, as he first fixed speeches in his memory.

Failure of memory takes place in a variety of ways. It is sometimes general, and extends to every subject; but it is frequently far more manifest on some subjects than on others. Salmuth mentions a case, in which the affected person had forgotten to pronounce words, but could nevertheless write them. Mr. J. Hunter was suddenly attacked with a singular affection of this kind in December, 1789, when on a visit at the house of a friend in town. He did not know in what part of the house he was, nor even the name of the street when told it, nor where his own house was: he had not a conception of any thing existing beyond the room he was in; yet was perfectly conscious of the loss of memory. He was sensible of impressions of all kinds from the senses; and therefore looked out of the window, although rather dark, to see if he could be made sensible of the situation of the house. The loss of memory gradually went off; and, in less than half an hour, his memory was perfectly recovered. This might possibly be connected with a gouty habit, to which Mr. Hunter was subject; though not at this time labouring under a paroxysm.

Boerhaave, however, gives a still more extraordinary instance of oblivion;—in the case of a Spanish tragic author, who had composed many excellent pieces, but so completely lost his memory (in consequence of an acute fever), that he forgot, not only the languages he had formerly learned, but even the alphabet; and was hence under the necessity of beginning to read again. His own poems and compositions were shown him; but he could not be persuaded that they were his productions. Afterwards, however, he began once more to compose verses; which had so striking a resemblance to his former writings, that he at length became convinced of his being the author of them.†]

These things are very curious. They occur in different circumstances; but they are, no doubt, of the nature of paralysis; and very frequently they are united with it.

## SECTION II.—PARAPLEGIA.

*Symptoms.*—In paraplegia (so called from *παρά*, *badly*, and *πᾶσι*, *to strike*), or that form of palsy which affects one-half of the body *horizontally* divided, both sense and motion are generally lost. There is, very frequently, constipation and retention of urine. At last, however, the sphincters become paralyzed; and there is neither retention of urine nor costiveness; but both feces and urine pass involuntarily. In this form of paralysis, it is very common for the affected parts to experience spasmodic twitches and catches. This is an occurrence comparatively rare in *hemiplegia*. Very frequently, too, there is violent pain. In *hemiplegia* there is *sometimes* pain; but by no means so frequently as in *paraplegia*. The urine, in this disease, is sometimes altered in quality. It is not sufficiently acid.

\* Dr. Abercrombie's "Inquiries concerning the Intellectual Powers," Part 3; Section 1; Subsection 5. (Ninth Edition; Pages 142 to 150.)

† Dr. Mason Good's "Study of Medicine;" Class 4; Order 1; Genus 6; Species 1; Variety 2.

It is perhaps alkaliescent; but when it is not, still there is a deficiency of acid; and, soon after it is passed, it becomes strongly alkaliescent. This is more particularly the case, when the paralysis has arisen from an injury to the spine.

*Progress.*—When paraplegia does not come on suddenly, it usually commences in the lowest part,—the toes; and extends upwards. Its extent is various; but it generally reaches a little higher than the hips.

*Causes.*—It is very frequently produced by a fracture of the vertebræ; and the higher the vertebræ in which the fracture takes place, the higher is the paralysis; and the sooner does death take place,—if death do occur. Caries of the vertebræ, also, frequently produces this affection. Any disease of the spinal marrow, and many diseases of the membranes, produce paraplegia. In some instances, the spinal marrow is softened into a pulp, at one particular spot. Sometimes it is exceedingly hardened; and sometimes the membranes, also, are exceedingly diseased. Sometimes there is suppuration,—producing compression; and sometimes an effusion of serum, or of blood.

All the diseases which I mentioned on the subject as occurring in the brain, and producing hemiplegia, and other forms of paralysis,<sup>a</sup> may occur in the spinal marrow, and produce paraplegia. Sometimes a clot of blood has been found; sometimes considerable hæmorrhage,—compressing the spinal marrow;—tumours of various descriptions;—exostosis of bone; as well as a mechanically altered position of the parts, diminishing the canal locally. I had a very striking case of this, in a boy who died of peritoneal disease. His peritoneum was filled with tubercles; and, besides symptoms of mesenteric<sup>b</sup> disease, he had lost the use of the lower extremities. The paraplegia was at once explained, by finding a scrofulous tubercle, as large as a nut, in the centre of the spinal marrow. The disease has frequently arisen from mechanical injury, when the bones appear to have sustained no violence. and in such instances I have seen recovery take place. In all probability, an effusion of blood had occurred, which was afterwards absorbed; or the parts received such a shock, as was equivalent to concussion of the brain. I can conceive that,—as an affection of the brain may be induced by mere concussion, and may last for a day, or a month, or months,—so a mere concussion of the spinal marrow may unfit it for its functions for a time; and the person may eventually recover;—at least, patients frequently recover from paraplegia, produced by a fall or a blow upon the spine. The softening which we observe, is sometimes the result of acute or chronic inflammation; and sometimes it is not the result of inflammation at all; but a morbid change not well understood.<sup>c</sup>

*Sometimes arises from Cold.*—Paraplegia sometimes arises from cold. I had under my care a man, who had lost the use of his lower extremities from working in cold water in a ditch;—digging the foundation of a wall, or something of that description. He was continually hard at work in damp, cold places. We rarely see *hemiplegia* produced in this way; the reason of which is evident. Cold is continually applied to the lower extremities *horizontally*, but it is very seldom indeed applied to the upper extremities *vertically*. The lower extremities are frequently in water, while the upper are not.

*Can it arise from Cerebral Affection?*—But besides all these causes in the spinal marrow, there can be no doubt that paraplegia arises, sometimes, from an affection of the head; because, occasionally, we find no uneasiness whatever in the spinal marrow; but there are symptoms of great uneasiness in the head; such as giddiness and drowsiness. Dr. Baillie wrote a paper in the “Transactions of the College of Physicians,”<sup>d</sup> to show that, in the greater number of cases of paraplegia occurring in adults, the cause was situated in the head. However, he did not prove the point at all. He gave but one dissection;<sup>e</sup> and that was not seen by him-

<sup>a</sup> See Pages 665 to 667.

<sup>c</sup> See Page 516.

<sup>b</sup> From *μεσος*, the middle; and *εντερον*, an intestine.

<sup>d</sup> Volume 6; Page 16.

<sup>e</sup> The bones of the skull, more especially at the sutures, were more vascular than usual. The “*dura mater*” presented nearly its natural appearance, but the vessels of the “*pia mater*” were very much loaded with blood; and there were effusions of serum between

self.<sup>a</sup> Whoever reflects on all the cases which he has seen of this kind, will find that, in the greater number of instances, the cause was evidently situated in the spinal marrow. He will arrive at this conclusion, from the cause having been applied to that part; from the uneasiness being felt there; or from the morbid appearances presented there on dissection; but occasionally there can be no question, that the disease arises from an affection of the head. I have seen a case of this description. The gentleman was a little poorly, and confined to his bed; but he had no great ailment. It was discovered, one day, that he had lost the use of his lower extremities; though no cause whatever could be assigned for it. He could not stand on his lower extremities. His urine had not passed; nor his feces. No violence, that he was aware of, had been applied to the spine, or to any other part; and he bore striking all down the spine. Pressure of the most violent kind gave him no pain. He told me, however, that he had had symptoms of giddiness a day or two after he was first seized; and delirium came on. The cause in this case was evidently situated in the head; but I am satisfied, that for one case where the cause of paraplegia is situated in the head, there are eight, or ten, or perhaps a dozen, where it is situated in the spinal marrow.

*Morbid Appearances.*—Sometimes, after paraplegia, no morbid appearance is to be found;—exactly as is the case after apoplexy and hemiplegia. In the two latter diseases, I stated, frequently nothing wrong is found in the brain;<sup>b</sup> and in the former, occasionally, nothing wrong is found in the spinal marrow.

*Cause of the Spasms.*—The reason why we have spasms, twitchings, and considerable pain in this disease, is that it is so frequently produced by a certain degree of inflammation of the spinal marrow;—an inflammation that softens it; or by something pressing on the spinal marrow, or at any rate producing great irritability. The cause which compresses the spinal marrow, also irritates it at the same time; and the irritation produces such an affection of the roots of the nerves, that a sense of pain is felt; and if it be a nerve of motion, a spasm occurs. When the part is found compressed by a bone, and this compression is only partially established, then we have considerable twitchings.

### SECTION III.—GENERAL TREATMENT OF PARALYSIS.

*Surgical Treatment.*—I will now consider the treatment of paralysis in general; or, at least, the treatment of hemiplegia and paraplegia. If there be a local cause evident and removable, our first plan is to attempt its removal. If the cause be a fracture of the cranial bones, of course surgical means should be immediately adopted, for removing such a source of irritation. If there be suppuration from a carious bone, or injury of a bone, measures should be taken (so far as accordant with the best surgical discoveries) for letting out the pus. I have seen pus let out by trephining the head, and opening the “dura mater;” but success, in such a case, must be very doubtful. The removal of a portion of fractured, or carious bone, is always to be attended to, when such serious effects take place as paralysis. If the cause be any thing taken into the stomach, we should endeavour to remove it.

*Antiphlogistics.*—Suppose the disease appear to be of an inflammatory nature;—if the head be hot, and there be violent pain; together with delirium, and things

the different membranes of the brain, on both sides of it. The “tunica arachnoidea” was opaque, and much thickened. The substance of the cerebrum was considerably firmer, and that of the cerebellum was considerably softer, than is natural. About four ounces of water were found in the lateral ventricles of the brain; and a considerable quantity of water was discharged from within the theca of the spinal marrow.—“*Medical Transactions, published by the College of Physicians in London,*” Volume 6; Page 22.

<sup>a</sup> The account of this examination, was communicated to me [Dr. Baillie] by Mr. Pennington, of Montague Place; who had attended the patient for many years.—“*Medico-Chirurgical Transactions,*” Volume 6; Page 23.

<sup>b</sup> See Pages 515, 665, and 666.

of that description; then, of course, common antiphlogistic treatment should be put in practice;—such as bleeding, purging, leeching, mercurializing as quickly as possible, applying cold, and starving the patient. This is the proper treatment of many cases of paralysis. In the first instance, we must treat the complaint according to the symptoms of congestion or fulness; but (as in the case of apoplexy) we must be on our guard not to go too far;<sup>a</sup> for if we do not attend carefully to the patient's pulse, every time we visit him, and do not visit him frequently, we may be surprised some day to find the pulse low, and the patient sunk irrecoverably.

*In the Chronic Stage.*—It is possible that paralysis may remain long after the inflammation is over; when the *effects* of inflammation only continue; when there is mere effusion left, or suppuration; or when the brain is softened, and there is no inflammation or congestion. At any rate all the patient's strength is gone; so that we should not be justified in severe measures, even if inflammation or congestion did exist. Great care is necessary, in this disease, not to push matters too far; and when there appears no danger of life, but the disease still continues, we have, in general, to carry on a certain degree of antiphlogistic treatment;—to make the patient abstain from wine, and from distilled liquors, and frequently from animal food. But we must not starve the patient too much; nor bring him too low in this chronic treatment.

*Mercury and Iodine.*—Mercury is very useful at first; but, after a time, it would only impair the powers of the patient: and after having given it a fair trial, it is a pity to have recourse to it again. Iodine has been strongly recommended, and will act as well as mercury; but it is only proper when rubbed in, in the form of ointment; and given internally, in combination with potassa. It is said to do good, and I have occasionally seen it useful; but when we consider that the disease may arise from so many different causes, it cannot be expected that any one thing can be of general use.

The plan most generally useful, is antiphlogistic treatment; because it removes congestion and inflammation; and prevents the parts from being pressed upon, by an excessive quantity of blood. If by chance any thing that ought to be absorbed supervene, antiphlogistic treatment will cause absorption, better than any thing else; and should there be some morbid growth, this may also be diminished by the same treatment.

*Local Applications.*—Local means, and counter-irritation near the part affected, are very proper;—that is to say, counter-irritation in the nape of the neck, where the *head* is affected; and down the *spine*, where the cause is situated there (as in paraplegia).

*Tonics.*—But, while adopting these measures, it is often very necessary (although we would not give *wine*) to give good food; and occasionally even tonics, and, after a time, they are often to be given rather freely. If there be great debility, we must not be afraid of giving wine. Patients will sink without it; and it will do no harm.

*Opium.*—To lessen the twitches and violent pain, opium is sometimes proper. If we keep the bowels open, and restrict the patient from improper stimuli, we may give opium; for it is a great advantage to lessen the pain and spasms. I have often administered opium, and never saw it do any harm; but, of course, I have always given it very cautiously. Though I am not habitually fearful with respect to medicine,—when I know my way, and know what the medicine is,—yet I am, at the same time, very careful in watching the effect of every dose; that I may stop before any harm takes place. There is no occasion to be *rash*, because we are *bold*.

*Strychnine.*—Where there are no signs of inflammation left, and the patient is languid, then stimulants may be given. On this account, strychnine has been particularly recommended; for although it is a narcotic, that will destroy life, it is a powerful stimulant to the nervous system. It will cause parts to twitch; and, while it stimulates the nerves of *sensation*, and the central parts of the nervous

<sup>a</sup> See Page 524.

system connected with them, it at the same time stimulates those of *motion*;—producing spasm, twitching, and a tingling sensation. It must, however, be obvious, that strychnia cannot be of universal, or even general use. If a part of the nervous system be softened, and disease is induced by it, how can strychnine, or all the stimulants in the world, cure the affection? We cannot, by such means, make a *soft part hard*. We may stimulate the part for a time; but that will not cure the disease. If the disease arise from pressure, how can any stimulant whatever remove it? It cannot have the effect of removing an exostosis, or a tumour. I cannot say that I ever saw a case cured by it, unless the disease arose from mere torpor. Where it arose from cold, then we may suppose, beforehand, that stimuli will do good, and I think I have seen strychnine serviceable in such cases. In common cases of paralysis,—arising (as they often do) from disease of the brain, where the parts have been softened in consequence,—we might give strychnine till the patient jumped out of bed; but it would only be to lie on the floor. I have given it freely; but I am not satisfied with it.

*Other Stimulants.*—Nux vomica, camphor, cayenne pepper, musk, and ammonia, have been had recourse to; and have failed. Electricity and galvanism, I should say, stand upon the same level, in point of utility, with strychnine and other stimulants. They may do good if the disease arise from mere torpor; but if the disease arise from an organic cause, or from compression, or obstruction, or alteration of structure, it cannot be supposed they will do good;—according to the extravagant idea which some persons have formed of them. There can be no doubt of the occasional efficacy of strychnine; but if we look at the pathological state of the disease, we must perceive how futile it must often be.

*Sometimes ceases spontaneously.*—Paralysis will sometimes cease spontaneously when the cause is in the brain. If it arise from effusion, the fluid may be absorbed; and by proper treatment we may expedite the absorption; but after a time, if we do nothing, it will be absorbed;—just as congestion will cease after a time. A clot of blood may be absorbed: and whatever had been used,—whether electricity or strychnine,—of course it would have the credit of it—but if we try a series of cases, and treat them with one particular remedy, we shall find the latter fail in a great number of instances. After all, the antiphlogistic treatment is evidently more successful than any other; only it is necessary to remember that, after a time, it must not be pushed too far.

#### SECTION IV.—LOCAL PALSIES.

I now proceed to more limited palsies than the foregoing;—to what are called “*local palsies*.” The most common local palsies affect the four organs of sense;—the eyes, the ears, the nose, and the tongue; the side of the face as to motion only; the upper eyelid as to motion only; a leg or an arm as to sense or motion; and the hands as to motion only. The cause of these local palsies is more frequently situated in the course of the nerves, after they have quitted the cerebral mass, or at the ends, than anywhere else. If the cause of palsy be in the brain itself, or in the spinal marrow, then we generally have more than local palsy;—either hemiplegia or paraplegia. But if the nerves be affected in their course, after leaving the brain, or only at their extremities, then we generally have local palsy.

*Amaurosis.*—The first of these of which I will speak, is one of those affecting an organ of sense. It affects the optical nerves; and is called “*amaurosis*.”

*Symptoms of Amaurosis.*—In this affection (which is also denominated “*gutta serena*”) there is dimness or loss of sight, without any fault of the humours, or the capsules, or the cornea, or the conjunctiva. Frequently, on looking into the eye, we see that, at the bottom, it is lighter coloured than it should be; or that it is rather greenish. The iris is sluggish or immovable; and generally the pupil is dilated. Sometimes, however, it is very much contracted; which arises from

irritation of the third pair of nerves. Indeed, from an affection of the third pair, the iris is sometimes not obedient to the light.

*Causes.*—The cause of this disease is in the expansion of the optic nerve, (the retina,) or in the course of the nerve itself; perhaps at the very origin (or termination),—the “*corpora quadrigemina*.” Sometimes it arises from *softness* of the nerve; sometimes from extreme *induration*; sometimes from tumours pressing upon it. I knew a young lady who was amaurotic, from seven years of age till the time she died; which was between twenty and thirty. A tumour was found pressing on the optic nerve. Disease of the “*corpora quadrigemina*” frequently produces this affection; and so also does disease of the “*thalami nervorum opticorum*.” The latter is often softened, however, without any affection of the eyes.

In this disease, there is very frequently headache, vertigo, and evident signs of cerebral congestion; but a very curious point in this disease is, that it will sometimes arise from an injury of another nerve than the optic. It has been known to arise from a wound of the supra-orbital nerve, and various nerves of the face. There are on record many cases, where amaurosis arose from an injury of some other nerve. Mr. Wardrop mentions several cases.\* It there appears, that where the nerves of the face (the supra-orbital, for example) have been only half divided, the complete division of the nerve has restored the sight; so that *imperfect* division produced amaurosis, and *complete* division cured it. It happened to me, in 1815, to see an instance of this description;—in the case of a woman, aged twenty-seven, who could only see one portion of objects. In her it had arisen from arteriotomy in the temple. There could be no doubt that, in performing the operation, a twig of the nerve was injured; and, from that moment, she partially lost the sight of the corresponding eye. This is a very curious circumstance;—one with which I was not acquainted when I began practice; and one with which many persons, I believe, are still unacquainted. I presume it is from sympathy. Diseases will frequently arise from sympathy of the head with the stomach; and so I believe that, in this case, the circumstance arises from sympathy; and not from any connection of function between the parts.

*Hemeralopia.*<sup>b</sup>—Amaurosis is singular in another respect. It is very frequently a *temporary* or *periodical* paralysis. Some persons become amaurotic at night, though they can see well during the day; and this is called “night-blindness,” or “hemeralopia” (from *ἡμερα*, *day*; and *ὤψ*, *the eye*);<sup>c</sup> or (incorrectly) “nyctalopia” (from *νύξ*, *night*; and *ὤψ*, *the eye*).<sup>d</sup> It is common in hot climates; and especially occurs in new-comers. It is said to be produced there, in that particular instance, from the great glare of the sun;—just as sheep are sometimes amaurotic in the spring, from being exposed to the glare of snow during winter; for it is observed that, in some mountainous parts, the sheep do not see till the commencement of summer;—till the snow has disappeared for some time. None of us can

\* In his “*Essay on the Morbid Anatomy of the Human Eye*.” Second Edition; Volume 2, Page 192.

<sup>b</sup> Dr. Mason Good has proposed *Paropsis* (from *παρά*, *bad*, and *ὤψ*, *sight*), as the generic name of this affection; and *P. Lucifuga* (night-sight), and *P. Noctifuga* (day-sight), instead of Nyctalopia and Hemeralopia. The Greeks employed the term “*Nyctalopia*” in the *literal* sense,—*night-sight*; “in consequence of the person labouring under it being only able to see at night, or in a deep shade; while it has been used by modern writers in the opposite sense of *night-sight-ache*;—agreeably to the *technical* or implied meaning of “*opia*,” when employed pathologically; in which case it always imports diseased vision, as though a contraction of the term “*paropia*” or “*paropsis*,” whence “*nyctalopia*” has necessarily been made to import “*day-sight*,” instead of “*night-sight*,” or that imperfection of vision in which the eye can only see in the day, or whenever there is a strong light. And hence “*hemeralopia*,” the opposite to “*nyctalopia*,” has been used, with the same confusion and contradiction of terms;—by the Greeks importing *day-sight*, being taken naturally or literally; by the moderns *day-sight-ache*, and consequently *night-sight*, being taken technically or by implication.”—“*Study of Medicine*,” Chapter 4; Order 2; Genus 1, Species 1.

<sup>c</sup> A defect in the sight; consisting in being able to see in broad *day-light*, but not in the *evening*.—Dr. Hooper’s “*Medical Dictionary*.”

<sup>d</sup> A defect in vision, by which the person sees *little* or *nothing* in the *day*, but in the *evening* and *night* sees tolerably well.—Dr. Hooper’s “*Medical Dictionary*.”

see at first, when we enter from the light into a dark room; and that is the same occurrence, on a small scale, which takes place in sheep that have been exposed to the glare of the snow. This has been observed, by some persons, to take place on board a ship. It has been noticed on the sea-coast, in the West Indies, in negroes, and in sailors near the equator. It is described by Mr. Bampfield, who wrote on Dysentery, as very common; and Sir Gilbert Blane mentions having seen it, in connection with scurvy. In general, it will yield with the other symptoms of scurvy; and when it will not, Mr. Bampfield says that, in all cases, it yielded to blisters applied to the temples. Dr. Heberden mentions an instance of night-blindness, in a person who never had it except on board ship.<sup>a</sup>

*Nyctalopia.*<sup>b</sup>—On the other hand, *day-blindness* is mentioned, by various writers, as occasioned by a dilated pupil, and occurring in Italian peasants. Regularly, at sun-set, persons in this situation become either perfectly blind, or very nearly so;—the light which occurs then not being sufficient for them. I had a case of this kind in a woman, who had been suckling four months: she said that she had always dimness of sight at five o'clock in the afternoon. This was in the neighbourhood of London. After lying down, and putting out the light, she gradually saw more clearly as the night proceeded; but when midnight arrived it became duller; and remained so till nine the next morning. She had nausea in the morning. I never saw her again. This woman was suckling; which might be too much for her. At five o'clock her sight began to be impaired; and she went to bed early. She had what is called "*ptosis*;"<sup>c</sup>—a dropping of the upper eye-lid.

*Dyseceæ.*—The hearing is often lost; but more frequently from other causes than paralysis. The affection is called "*dyseceæ*."

But it is not uncommon for smell, hearing, and taste to be paralyzed, when there is paralysis of another kind. Sometimes in *hemiplegia*, sometimes in *paraplegia*, we see a person lose smell and taste, or smell and hearing. It is rare that smell and taste are paralyzed; except in conjunction with other kinds of paralysis. When the cerebrum is diseased, several kinds of paralysis occur; as well as epilepsy, and other nervous diseases.

*Paralysis of the Portio Dura.*—The most common partial paralysis, which affects motion only, is that of the face; and this chiefly arises from an affection of the "*portio dura*." When this partial paralysis occurs, it cannot be mistaken for a moment. The face is drawn to the opposite side; and the eye of the affected side remains wide open, while the other is shut. The consequence of this is, that the tears are not directed towards the inner canthus of the eye, but fall over on to the cheek. There is an inability to laugh; so that if the patient attempt it, he laughs "on the wrong side of the mouth." There is an inability to distend the cheek; and an inability to whistle or frown. If he frowns, he does it with only one "*corrugator supercilii*;" and as to whistling, he makes all sorts of noises out of the other corner of the mouth. Sensation is, in this case, unimpaired. The "*portio dura*" being a nerve of *motion*, and not of *sensation*, motion only is paralyzed.

*Causes.*—This affection generally arises from cold, but not always. Very often the patient is deaf at the same time; and he has a discharge from the ear. This may be conceived, from the situation of the "*portio dura*;" indeed, it often occurs in persons who have been exceedingly deaf. Sometimes it arises from caries of the bones; and sometimes it has appeared to arise from an enlargement of the gland behind the ear, compressing the nerve. Sometimes this paralysis is evanescent; and if we apply a stimulating liniment, it soon disappears. It will disappear spontaneously; but I dare say it disappears much sooner on stimulating the part. Occasionally, however, it is tedious and incurable. I have seen cases in which it

<sup>a</sup> "Commentaries;" Chapter 66.

<sup>b</sup> "Nyctalopia" and "hemeralopia" change meaning, in the hands of different authors: Nyctalopia, if understood as "day-blindness," may arise from dilated pupil, thin "pigmentum nigrum;" or a too sensible state of the retina. The contrary of either of these states causes hemeralopia. Nyctalopia is sometimes epidemic; especially if the ground be covered with snow.—*Dr. Fletcher.*

<sup>c</sup> From πτω, to fall.

has been much improved; but I hardly recollect a case where the cure was quite perfect. It would be very wrong to suppose (as has been intimated too frequently) that this kind of paralysis has no connection with an affection of the head. It *may* have no connection, because it may be external to the brain,—external to the “foramen ovale;” but, in many cases, patients have fulness of the head, giddiness, sleepiness, and other symptoms; which clearly show that there is an affection of the head, as well as of the nerves. The “portio dura” may suffer compression, and become softened, within the head; as well as in the bones of the cranium, and after it has left those bones. It is by no means a trifling complaint; and very often *is* connected with a more serious affection.

*Treatment.*—The proper mode of treatment would be, to ascertain how far there is an internal affection or not. If we find symptoms of drowsiness, they must be treated the same way as in other cases; but even if we find nothing of that description, still there may be a propriety in applying leeches over the “portio dura” (about the mastoid process), rubbing in mercury and iodine, stimulating the parts well, and applying blisters. I have done all this, and with a certain degree of success; but (as I just now said) I hardly recollect a case which, after continuing some time, was perfectly cured. Repeated leeches, blisters, mercury, stimulating applications, and frictions, I believe, are the best things we can employ.

Some have thoughtlessly proposed to divide the “portio dura” of the opposite side,—in order to paralyze the other muscle. This would do very well, if it were antagonized; but, unfortunately, the “orbicularis palpebrarum” is a distinct muscle; and therefore the effect of cutting it would be, to prevent the patient from shutting either eye. It would prevent the affected muscles from being drawn to the healthy side, but both eyes would remain staring wide open; and the patient would thenceforward be unable to make use of the muscles at all. He could neither whistle nor laugh.

*Paralysis of the Fifth Pair.*—It sometimes happens, that the nerve of *sensation* of the face is affected. The “portio dura” is a nerve only of *motion*; but there is another nerve which gives *sensation*; and not only to the face, but (as it would appear) to the nose and the other organs of sensation in the head. Paralysis, in this case, is much more rare than in the other.

A very interesting case is recorded by Sir C. Bell, in which the following appearances were presented:—“The left side of his face is relaxed, and the natural balance of the features is gone,—so that the countenance has a distorted, wry appearance. The left eye stares widely and unnaturally open, while the right is only moderately disclosed. When he makes an attempt to close the eyelids, the left remains unmoved; but the eyeball is elevated upwards; and it is raised to so great an extent, that the pupil is quite concealed beneath the upper lid;—the white of the eye only being exposed. He is unconscious of the eyeball thus revolving upwards; the objects around him in the ward, are not seen while it takes place. He was told to direct his eyes, so as to look as straight above him at the ceiling as he could; when he did this, it was observed that he could not raise the pupil by his utmost efforts so high, by some degrees, as during the involuntary act. When turned up in the effort to wink, the cornea rose so as to be presented towards the roof of the bony orbit, and so as to be quite concealed by the eyelid; and, on the other hand, when he looked upwards at the ceiling, more than one half of the pupil was disclosed. During sleep, the eyelids remain wide open; and the pupil is concealed;—just as is observed at the time he winks. It is remarked, that the globe of the eye protrudes considerably more than the other; the conjunctiva is inflamed, and is loaded with numerous blood-vessels. He says, that he suffers pain from his eye being constantly open; especially when he is sitting before the fire, at night. When he is told to frown, there is no motion perceived on the left side of his forehead; but all the expression seems drawn to the right side. When made to laugh, the features are curled up, in the expression of laughter, only on the right side of the face; which presents a singular contrast with the sad, or rather lifeless appearance of the left or paralyzed side. When a spoon was put into the left angle of his mouth, he could not grasp it: he said that, in eating, he put the morsel into

the right side. The left nostril is not dilated in a corresponding degree with the right; and the difference between them was most distinctly seen, when he attempted to snuff up the air, or to breathe hard; for then, while the right nostril expanded more widely, this one became quite collapsed, and shut up against the air. The sensibility of the skin, over the whole of the head, is perfect; and the muscles of the jaws act powerfully. He can move his tongue about in all directions. There is a greater fulness over the left temple and jugum, than over the right; there is also a blueness of the integuments, consequent on the injury he had received; but he does not even wince if this part be pressed severely. There is an enlarged gland in the hollow under the left angle of the jaw; and it gives him pain when pressed. The whole chain of the 'glandulæ concatenatæ' on the left side of the neck, are enlarged and tender. His hearing is not affected, and there has been no discharge from the ear. He says that, for some days, his head has been drawn towards the right side; but this is now gone, and he can hold his head erect."<sup>a</sup>

In an affection of the "portio dura," the patient *feels* as before; but as, in this case, there was disease of the *fifth* pair, there was no sensation in the face. It might be pinched and scorched, the eye might be rubbed, and the internal part of the nose might have substances introduced; but yet no sensation was experienced. There was, however, no distortion of the face,—no want of power over the muscles of the face; which clearly showed the distinct uses of the "portio dura," and of the fifth pair. I must mention, however, that the "temporalis" and "masseter" muscles were paralyzed; because the fifth pair is not altogether a nerve of *sensation*;—there are branches in it of *motion* likewise. This particular case arose from mechanical injury.

If this particular nerve be divided intentionally within the cranium (which may be done by practice and dexterity), the external parts which it supplies lose their sensation; and, after a time, the eye becomes muddy, and the cornea opaque. This result I saw, when Magendie made his experiments; and many others have witnessed it.

The treatment of a case of this kind, can only be conducted on the general treatment of paralysis;—exactly as in the case of disease of the "portio dura."

*Anæsthesia*.—Paralysis of the sense of touch, which is called "anæsthesia," is also very rare. It is common enough for persons to lose *sensation* and *motion* in hemiplegia; but to lose the sense of *feeling only* is very rare. A case, which arose from cold, is described in the third volume of the "Medico-Chirurgical Transactions," by Dr. Yelloly.

[The following are the principal circumstances which I<sup>b</sup> have had occasion to observe relative to this case. The hands, up to the wrists, and the feet, half way up the leg, are perfectly insensible to any species of injury; as cutting, pinching, scratching, or burning. The insensibility, however, does not suddenly terminate; but it exists (to a certain degree), nearly up to the elbow, and for some distance above the knee. He accidentally put one of his feet, some time ago, into boiling water; but was no otherwise aware of the high temperature, than by finding the whole surface a complete blister on removing it. No species of injury to a vesicated part of either hands or feet, is felt by him. The extremities are insensible to electrical sparks taken in every variety of mode. The cubital nerve, where it passes the elbow, communicates the sensation produced by pressure or a blow only half way down the forearm. He perspires much on the left side, just about the hip; but nowhere else. He is generally rather chilly; and the extremities are cold, except when he is in a comfortable room; in which case they are of the usual temperature of the body. The thermometer, however, rises to 101° in the mouth. The hands are somewhat of a purple colour. If he wishes to ascertain the temperature of any body, he is under the necessity of putting it to his face or neck, or the upper part of his arm. His skin seems to be more than usually sensible to the

<sup>a</sup> Extracted from a Clinical Lecture by Sir Charles Bell; published in the "London Medical Gazette;" Volume 3; Page 341. (No. 63; February 14, 1829.)

<sup>b</sup> Dr. Yelloly.

effects of heat. On putting his hand, at the desire of a friend, into a pail of hot grains,—which his friend assured him were not too hot, and (to convince him of it) previously thrust his hand and arm into them,—there was a very extensive vesication produced. His hands are never free from blisters, which he gets by inadvertently putting them too near the fire; and he has met with several severe burns, without being aware of them; no degree of pressure is felt by him, but a blow produces a slight degree of tingling. He has a general uneasy sensation in the extremities, which warmth rather relieves. His skin, in general, heals very readily, after being burnt or scalded in the most severe way; and there is no fever; (as far as he has been able to determine,) nor any increased heat or throbbing during the process of healing. This seems to be also the case with some other parts of the body, which are not altogether insensible; for, a little time ago, he got burnt in the front of the patella; and, though there was a considerable slough separated in consequence, he suffered no pain, and little inconvenience during the cure. If the heat to which the insensible parts are exposed is moderate, vesication is not immediately produced. The part becomes red; and in a few minutes, but sometimes not till the lapse of an hour or two, is blistered. That a smaller than ordinary temperature produces vesication in this individual, seems to be ascertained by the circumstance, that exposure to the heat of a common fire gave rise to a blister on the knee, which was followed by the slough above mentioned; though the clothes which covered the part were not at all injured. Immersion in water at  $120^{\circ}$  produces no change in the affected parts; but exposure to the same temperature, at a common fire, speedily blisters. That degree of heat, is (as far as I can judge by myself) about the utmost which can be long borne by the hand, in ordinary circumstances, without pain.

Cold water, and warm water of every temperature, invariably appear lukewarm to him. Water at the freezing point produces no degree of sensation whatever; but when his hand is kept in it for some time, he feels a slight coldness at the end of the thumb. After his hand had been immersed in water of the common temperature, and was introduced into water of  $32^{\circ}$ , he had some sensation of warmth. The cold produced by means of a mixture of snow, or ice and salt, communicates no sensation, except a slight chilliness in the thumb; and when this freezing mixture follows the use of water of the common temperature, it produces a slight degree of warmth. A solid body produces no sensation, whatever the temperature may be. The power of motion exists in the muscles of both hands and feet. With the former he can grasp pretty firmly; but, in holding any thing, he is apt to drop it, if his attention is called away. There has been of late a slight loss of substance in the hands. He can lift a chair; but cannot raise himself from the ground, by taking hold of any thing placed above him. The susceptibility of impression generally, as well as the muscular power, appear to be somewhat diminished. The functions are natural, and the pulse regular and moderate.

In the treatment of these symptoms, no advantage has been derived from any plan which has been adopted either by others or myself. The warm bath, electricity, galvanism, tonics, the *rhus toxicodendron*, and mercury (given with a view to its action on the bowels, and on the system at large), have been equally unavailing; though it must be owned, that the patient has never shown a sufficient degree of perseverance, in the prosecution of any means which have been adopted for his relief.<sup>a</sup>]

A case is recorded in the fourth volume of the “*American Repository*,” where the hands and feet were affected in the same way. The man was looking another way, and cut off his thumb without knowing it; and when he looked at his hand again, it was gone. This man frequently met with accidents, from treading on things which he ought to have avoided. He had burns and wounds in his hands and feet. He continued in this state for two years. There is an instance mentioned by Laennec, in his second volume, where the right arm was broken; but

<sup>a</sup> “*Medico-Chirurgical Transactions*,” Volume 3; Pages 92 to 95.

the patient knew nothing about it, till he found he could not use it as before. All these persons were in the middle period of life, between forty and sixty years of age. I have never seen an instance of it.

*Paralysis of a Limb.*—There are some interesting and curious cases of partial paralysis of sense and motion, which occur rather suddenly, and in only one extremity. It is well to know these cases. I have never seen one; but they occur from time to time. The extremity has been the arm, in almost every case. It has become suddenly cold, motionless, and senseless; and it has then mortified. This has not been from inflammation; but, becoming paralytic first, the limb has presently mortified; so that frequently the whole case has not lasted more than a few days. One of the earliest instances with which I am acquainted, is mentioned by Dr. Wells.<sup>a</sup> In that case it took place in the left arm; but the arm was not examined. Another case occurred in the *right* arm; and was followed by death in a few hours. It was observed, before death, that the arm was only pale; and it is said that nothing morbid was seen at the autopsy. There is another case mentioned, where both the arm and leg, in hemiplegia, lost the pulse entirely; and there death took place in five days. But the nature of such cases has now been pretty well cleared up. It appears that some have taken place after external violence. The external violence has lacerated the inner coat of the artery, and an effusion of lymph has blocked up the vessel;—so that the part has been deprived, almost immediately, of all blood; and the consequence of it, in the first place, was a loss of sensation and motion, and afterwards mortification. In the “*Edinburgh Medico-Chirurgical Transactions*,”<sup>b</sup> there is a paper well worth reading, communicated by Mr. Turner, a surgeon; who found a laceration of the internal coats, and complete obstruction. In other cases there appears to have been no external violence; but the artery has been previously diseased, and has suddenly given way in the inner coat; so that inflammation has been set up, lymph effused, and obstruction produced in that way. Occasionally the obstruction takes place from an accumulation of pus. These cases were mysterious before the arteries were examined.

These, I believe, are almost the only cases of partial paralysis, in which the pulse is lost in the paralyzed part. In most paralyzed limbs, it is weaker than in other parts of the body; but where it ceases altogether, it arises from a disease of the artery;—such as I have now mentioned. Magendie mentions a case of diseased nerves, producing such symptoms as I have stated; and, after death, the fifth pair was found swollen, with a grayish yellow-coloured matter.

*Diseases of the Nerves, a Cause of Local Paralysis.*—The diseases of the nerves which give rise to this partial paralysis, are precisely the same, though different in *situation*, as those which give rise to hemiplegia and paraplegia.<sup>c</sup> In some instances it is entirely mechanical compression. *Hemiplegia* may arise from the compression caused by a tumour on the *brain*; *paraplegia* from the compression caused by a tumour in the *spinal canal*; or the pressure of a bone that is fractured; and so may amaurosis (which is a partial paralysis) arise from the pressure of a tumour on the optic nerve. Any cause that will produce paraplegia or hemiplegia, will produce local paralysis when differently situated. Occasionally this local paralysis arises from local inflammation of a particular nerve; and the inflammation may be of so intense a character, as to be seen after death; and, indeed, we may see ecchymoses. Sometimes there is softening of a particular nerve, —even ulceration of it; and a decided effusion into its sheath. These are precisely the same things that I mentioned, as causes of hemiplegia and paraplegia.<sup>c</sup> Tumours have frequently been found resting on particular nerves; and when there are these circumstances (inflammation, softening, ulceration, and tumours), there are often paralysis, violent pain, and spasmodic convulsive action of the muscles which these nerves supply.

<sup>a</sup> In the “*Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge*,”—a work which only consists of a few volumes; but which contains papers of the highest importance by Dr. Baillie, John Hunter, and others.

## BOOK III.

### DISEASES OF THE RESPIRATORY ORGANS.

---

#### CHAPTER I.

##### BRONCHOCELE.<sup>a</sup>

*Definition.*—THE disease to which I shall next direct your attention, is situated in the neck, outside the air-tubes;—in the gland called “thyroid.” This disease is called “bronchocele;” from βρογχος, *the windpipe*; and the substantive of which we make so much use,—*νελη*, a tumour. The French call it “goitre;” and it is supposed that this is a corruption of the Latin word “guttur,” *the throat*.

*Characters of the Tumour.*—THE disease occasions a swelling in the front of the neck, in the situation of the thyroid gland;—a swelling produced, in fact, by an enlargement of that gland. No disease would be called “bronchocele,” although a swelling in the neck, unless it were the result of an enlargement of the thyroid gland. This tumour is, for the most part, soft; and neither painful when left to itself, nor when touched; and therefore it is not tender. Although it is usually soft in almost every part, yet occasionally we find it hard in some one part;—of a cartilaginous, and (indeed) sometimes of a bony hardness. It may attain a large size, or it may be very small;—it may, in fact, be merely a general fulness of the gland, or a slight general enlargement. Very frequently it is enlarged chiefly, or almost entirely, in the centre, or on one side; and from being, at the beginning, a slight fulness of only one lobe of the thyroid gland, it may attain so enormous a size, as to hang down to the knees. Foderé, in his treatise on the disease, mentions an instance of a tumour which weighed seven or eight pounds; and Alibert mentions a tumour, occurring in a man thirty-eight years of age, which reached to the middle of the chest, was as large as a pumpkin, and looked like a pelican’s pouch. There is also one mentioned, as existing in a female upwards of sixty years of age. It extended from ear to ear; descended below the mammæ; impeded deglutition and respiration; and pressed on the “meatus auditorius,” so as to close it up. A German author mentions an instance of a goitre descending to the knees.

*Internal Structure.*—Its external appearance is sometimes uniform and sometimes knotty; and on cutting into the tumour, we find cells of all sizes, with contents of various consistency. Sometimes the contents are found gelatinous, and sometimes soft. Sometimes one particular part is cartilaginous, or even ossified; containing a quantity of calcareous matter. A variety of appearances are presented in various parts of the same tumour. Occasionally the tumour suppurates;

<sup>a</sup> In conformity with Dr. Elliotson’s plan,—to describe the diseases as they occur, *a capite ad calcem* (Page 70),—bronchocele, and certain affections of the mouth, stand next upon the list. And although some of them scarcely admit of being classed among diseases of the *respiratory organs*; yet their proximity to those parts will probably serve as a sufficient apology for their introduction under this head.

and sometimes disappears spontaneously. The blood-vessels of the part are found very much enlarged.<sup>a</sup>

*Progress and Effects.*—When the disease has begun, it usually increases; but occasionally it makes a stop;—does not, at a certain period of life, increase any more; and I have fancied that it has sometimes appeared to shrink in old age. Bronchocele may destroy life, by pressure on the neighbouring parts; and Dr. Baillie says he saw one or two cases, in which death took place from pressure on the œsophagus and trachea. I have frequently seen it affect the voice; so that a person spoke in a hoarse, croaking tone, and with a sort of hissing sound;—such as is produced when the trachea is pressed. The disease is not entirely confined to the human subject; but cattle, also, and dogs have it. It is very common for it to be less during the winter, and to increase again during the summer. It is said usually to begin in one lobe only of the thyroid gland.

*Influence of Age and Sex.*—This disease affects females more frequently than males; and usually it does not begin before the individual has attained eight or ten years of age. There are, however, exceptions to this. In the “London Medical Repository,” a physician mentions a child (in Derbyshire) who was born with a goitre of considerable size. At different times, when in Switzerland, I have made inquiry of the country people and of my guides; and one old peasant told me, that he knew an infant who was born with a goitre; and I saw one myself in a little boy only four years of age. However, the answer I usually received was, that the disease seldom appeared before six years of age;—nearly agreeing with what is usually stated by authors; who say that, in general, it does not begin before the eighth or tenth year. Indeed, I was told that not only bronchocele, but even cretinism (the idiocy of the country, which I formerly spoke of<sup>b</sup>) did not begin in early childhood. Some of these people have a notion that a child has a goitre, or is a cretin, if either of the parents was drunk at the time of conception. They ascribe these diseases to that cause; though not in every case.

*Hereditary in its Nature.*—As the disease is certainly seen in children, and they are sometimes born with it, and frequently the parents have goitres, it may be hereditary;<sup>c</sup> but although both parents may have goitres, yet (just as we observe with respect to other diseases) it does not follow that the progeny must have them too. A case has been mentioned to me of a goitrous father and mother, who had produced five children, all of whom were goitrous, and cretins; and of another pair (both goitrous) who had four children with goitre; and one, twenty-two years of age, who was neither goitrous nor idiotic. In fact, she was said to be “tall and genteel.”

*Frequently accompanies Cretinism.*—This disease frequently accompanies cretinism. When we see an individual with a large head, an “ace-of-spades” nose,<sup>b</sup> the eyes a mere slit, perhaps deaf and dumb, and imbecile, it is very common to find the thyroid gland enlarged; and it is asserted that if people, both having goitres, marry, and one of their children (having a goitre) marry another with a goitre, that their offspring (constituting the third generation) are sure to be something worse than goitrous,—to be cretins,—to be idiotic. This is asserted; but I do not know its truth from any observations of my own.

*Occurs in various parts of the Globe.*—We meet with this disease in various parts of the globe; and in all latitudes,—hot and cold. It is seen in England, France, Spain, Switzerland, Germany, China, Tartary, Bengal, the Island of Sumatra, Spanish America, and North America. Mungo Park says, that he saw it in the negroes of Barbary.<sup>d</sup> Some have ascribed it to the cold; but as it occurs

<sup>a</sup> There is a representation of the disease in Dr. Baillie's work.

<sup>b</sup> See Page 545.

<sup>c</sup> See Page 546.

<sup>d</sup> The negroes attribute this disease [the “Guinea-worm”] to bad water; and allege, that the people who drink from wells are more subject to it than those who drink from streams. To the same cause they attribute the swelling of the glands of the neck, (“goitre,”) which is very common in some parts of Bambarra.—“*Travels in the Interior of Africa; by Mungo Park.*” Chapter 21. (Page 59 of Chambers's “*People's Edition.*”)

among the negroes in Barbary, and also at Bengal, it cannot be owing to the cold. Some have ascribed it to snow-water; but there is no snow either in Barbary or Bengal; and, on the other hand, the disease is unknown in Greenland and Lapland, where there is little else than snow-water, and where the weather is very sharp.

*Dependent on the Quality of the Water.*—It appears, however, to be dependent in some measure upon the water; for the waters in the rivers and lakes of Switzerland are always bad, and are drunk only by the poor and ignorant; and those who drink them heartily are, for the most part, sure to have the disease. Those who are above the very lowest,—the most abject class, do not drink the waters either of the rivers or lakes; but the most ignorant people do. I have seen them drinking water the colour of ink, in Switzerland, in 1826. I had an intelligent guide, who told me that, beyond all doubt, this water produced it; but those who drank spring or snow-water, which did not run along a bed of lime, escaped; and nearly all escaped who drank cascade-water. He said, that the bad water usually took about a year to produce the disease; but the instant the bad water in his neighbourhood was drunk by those unaccustomed to it, they found unpleasant effects. Sometimes, he said, these effects were prevented by putting a bit of ice or snow into it.

Dr. Richardson, in Captain Franklin's "Journal of a Voyage to the Polar Sea," makes an observation perfectly agreeing with the account which this man gave me. The captain says, that at Edmonton, on the banks of the Saskatchewan river, goitre is very common; that it is certain goitre affects only the drinkers of this water; and that, in its worst state, the disease is confined almost entirely to the half-bred women and children, who are always resident in the Fort, and make use of the river water; which is drawn, in the winter, through a hole made in the ice; whereas the men, from being often from home on journeys, and using snow-water, are less affected with goitre; and when they are at home in the winter, if signs of goitre come on, their annual summer visit to the coast presently cures them. He says the natives, who confine themselves to snow-water in the winter, or some of the small rivulets which flow through the plains in the summer, are exempt from the disease. A residence of one year at Edmonton, where the water is so bad, is sufficient to render a family bronchocelous. He says, that many of the goitres acquire a large size; and that burnt sponge has been tried, and found to remove the disease; but that drinking the water again, renews it. A great proportion of the children who have goitres (he says) are born idiots, with large heads and other distinguishing marks of cretins;<sup>a</sup> but he could not learn whether it was necessary that *both* parents should have goitres, in order to produce cretin children.<sup>b</sup>

Another year that I was in Switzerland, passing along a valley near the lake of Valteline, the guide told me that, in one of the populous villages, there was no spring; and the inhabitants are therefore obliged to drink the water of the river; which is so bad, that goitre is very prevalent there. But, in another village, there are plenty of springs; and nobody there drinks any water, except that from the springs; and no one has goitre. He also added, that where there is much goitre, they are all Catholics; whereas in the village where there are plenty of springs, the inhabitants are Protestants. This is rather an important remark; because it is a very striking circumstance that, on many parts of the Continent, the Protestant districts are much cleaner and more healthy than the Catholic districts. More frequently than otherwise we can tell the Catholic districts, by merely looking round, and observing the state of the peasantry, without asking a single question. The Catholics spend so very much time in praying, that they are dirty in their persons, and not at all industrious; whereas the Protestants are very clean;—not spending so much time in church-exercises; and they are better off altogether. No one who has travelled, can doubt the truth of this remark; and it is important to be

<sup>a</sup> See Page 545.

<sup>b</sup> "Narrative of a Journey to the Shores of the Polar Sea; in the years 1819 to 1822. By John Franklin." Chapter 4. (Third Edition; Volume 1; Pages 183 to 186.)

aware of the fact; because (as I shall have to mention\*) the worse people are off, the more subject are they to the disease, when the causes of it are applied.

[These facts seem to favour the notion (which is a popular one in goitrous districts), that bronchocele originates in some deleterious quality of the water. Indeed, it is impossible to examine the filthy beverage of some of these districts, without being convinced that pernicious consequences must ensue from its habitual use. Bally<sup>b</sup>—a native of a district in Switzerland, where bronchocele is endemic—states that, in his country, those who drink the waters of certain fountains are almost always attacked; whilst others of the same village who avoid these waters are not liable to the complaint. Rambuteau, also, considers that water impregnated with calcareous salts contributes to its development. Dr. Coindet observed, that almost every individual of a regiment who drank the calcareous water of the pumps at Geneva, was attacked with goitre; which disappeared rapidly upon their removal to other quarters. Its prevalence in Nottingham is ascribed, by Dr. Manson, to the same cause.<sup>c</sup>

Mr. McClelland has lately made extensive researches into the causes of bronchocele among the Himalaya mountains. His inquiries extended over one thousand square miles; and he invariably found limestone-rocks in the immediate neighbourhood of goitrous districts; while in villages where this stratification was not observed, the disease was rarely met with. When it was found in the latter places, Mr. McClelland could generally trace it to the use of water having its source in the limestone-rocks; and where these waters were avoided, the complaint seldom appeared. Unfortunately, however, there are facts which prevent the universal application of this theory respecting the origin of the disease:—  
1. Bronchocele is met with abundantly in districts where there are no limestone-rocks; as, for instance, in the Vallais. 2. It is absent in many places abounding in limestone formations. 3. It prevails in districts where the water is pure, and free from calcareous impregnations.<sup>d</sup> 4. A strict adherence to distilled water, is not sufficient to ward off the disease in affected places.<sup>e</sup>]

*Nature of the Water.*—The nature of the water which produces this disease, is not well known; but, in all probability, it is mineral. I *presume* it to be so, as the water contains so much lime; but I will not *assert* it. Captain Franklin states, that those inhabitants who reside sixty miles nearer the source of the river than Edmonton, are said to be more severely affected than those at Edmonton; and he says goitre is unknown at a distance from the river, where nothing but snow-water is drunk for nine months in the year. He adds that, still farther from the source than Edmonton, where the water is still turbid, the disease is unknown. It certainly appears to be connected with the water; and seems to arise from some impregnation which the water has near its source, and which it loses as it goes along. At Edmonton, Captain Franklin tells us, the river is clear, except from the month of May to that of July; and that the distance from the Rocky Mountains is one hundred and thirty miles. The neighbouring plain is alluvial, and the soil calcareous; with many fragments of limestone.<sup>f</sup> In Switzerland the cause of the disease would not appear to be in the water at its source; for the springs and cascades do not produce it. On the contrary, it is the water that runs along beds, and is found in lakes, that appears to give rise to it. Persons on the mountains are rarely affected; and those who remove from the valleys and places where it prevails, to the mountains, find the tumour in some degree alleviated; and, after a great length of time, the disease has been known to cease altogether. The disease prevails much more in valleys with high mountains around them (such as abound in Switzerland) than elsewhere; and perhaps in those which are most exposed to the east and south winds.

<sup>g</sup> Franklin's "Journey to the Polar Sea;" Chapter 4. (Third Edition; Volume I; Pages 184 and 185.)

*General Character of Goitrous Districts.*—Whatever may be the cause of the affection, it is found to prevail most where the air is worst;—where the mountains cause the air to be pent up, and where the persons are badly off.<sup>a</sup> It prevails in a particular valley in Switzerland (the *Vallais*) most frightfully; and there the people are worst off; for there more poverty and wretchedness exist, than in almost any other part. The inhabitants are dirty, and badly fed. In the countries where it is prevalent, the people have a dirty brown look, and appear withered;—as if they were in premature old age. It seems that the causes which produce the disease, are those which poison the habit generally, and render it more liable to be affected by the causes of this particular disease. They have an aguish, or *malaria-kind* of look; yet we sometimes have it where there is no ague; and we have ague where this disease does not exist. Any circumstance which throws the body out of health, may predispose to this disease. The particular circumstance of the patient having a withered look, may not be immediately connected with bronchocele; but the causes of the withered look may impair the constitution, and render the person constantly liable to become goitrous. My own guide told me, that where the inhabitants were dirtiest, and the worst fed, they were most subject to the disease. Dr. Good says that, in Derbyshire, “He found a much larger number of the poor affected with this disease than he had ever seen before, while the rich escaped; he found also that by far the greater part of those who were labouring under it, were not only exposed to all the ordinary evils of poverty, but derived their chief diet from that indigestible and innutritive substance, the Derbyshire *oaten cake*; which is probably the chief cause of all the glandular and parathyroid enlargements which are so common to that quarter.”<sup>b</sup> But this oat-cake is eaten in other parts of England, with no such effect.

*Diagnosis.*—[Although the tumour of bronchocele is in general sufficiently characteristic, it may sometimes be confounded with other affections. The thyroid gland is liable to inflammation; but this disease may be distinguished from goitre, by the hard unyielding character of the swelling; by its being accompanied with redness of surface, increased heat, and pain on pressure; by the suddenness of its appearance; by its not attaining the size of a goitrous tumour; and by its tendency to suppurate. The gland is sometimes affected with scirrhus.<sup>c</sup> In this case, however, only a small portion is usually affected; and differs from bronchocele in its extreme hardness, and in being generally the seat of severe lancinating pain. In scirrhus, also, the swelling seldom attains a large size. Encysted tumours sometimes form in the course of the trachea; and may be distinguished from bronchocele by their situation, by their compact form, and by their giving a sense of fluctuation. Aneurism of the thyroid arteries may be known from goitre by the pulsation which accompanies the former affection, by the situation of the swelling, and by its diminishing or disappearing under firm pressure.<sup>d</sup>]

*Treatment.*—The patient should certainly desist from drinking any water which may be suspected to be the cause of it. Burnt sponge is unquestionably useful in it; and many practitioners say that they have seen cases cured by it. It has been supposed that the good effects of burnt sponge, are to be ascribed to the iodine which sponge contains. I presume there can be no doubt, that it possesses a remedial power over the disease; and some unite it with sulphur.

*Iodine.*—By far the most efficient remedy, however, is iodine;<sup>e</sup> and it may be employed externally or internally. I have cured many cases of bronchocele,—some of them where the tumour was rather large,—with this remedy. It may be employed in the form of iodine itself; or it may be united with hydriodate of potassa; and that, perhaps, is the best way of administering it. With regard to the quantity, there is no rule for the dose; for it produces two effects,—constitutional and local. The constitutional effects are emaciation, morbid irritability of body,

<sup>a</sup> See Page 545.

<sup>b</sup> Congestive.

quickness of pulse, palpitation, and absorption of particular parts; more especially, it is said, the *mammæ* of women, and the *testes* of men. It likewise takes away the appetite; and is more or less injurious to the body at large. But besides that, it is a very acrid substance; and therefore, like any other acrid substance taken into the stomach, it will produce vomiting and gastritis, and even ulceration: and when it passes the stomach, it may produce diarrhœa, and more or less inflammation of the mucous membrane of the intestines. It affects the stomach and intestines immediately,—simply as a corrosive agent; and this may arise in one person from a small quantity, though it will not occur in another from a *large* quantity. We never know, beforehand, the disposition of the patient with regard to it; and therefore it is always best to begin with a small dose. There can be no impropriety, as the disease is chronic, in delaying an efficient dose for some time. We may therefore begin with five minims of the saturated tincture; and if no unpleasant effect be produced, it may be increased a drop every dose, or every *other* dose. I have gone so far as to give one hundred minims for every dose; but a great number of persons will not bear above twenty or thirty minims. Patients complain of heat of the stomach; but if we begin gradually, and inquire of the patient whether there is any burning sensation, or heat of the stomach, or any griping, we never need run the risk of doing mischief from its local effects. When a person begins to feel a dose (such as fifteen or twenty minims), I have been told that diarrhœa took place even with griping and bleeding;—owing to its being such a corrosive substance; and if a large quantity be taken into the stomach, the mucous membrane will soon be in a state of erosion.

*Hydriodate of Potassa*.—As to the hydriodate of potassa, there is scarcely any rule for the dose; but it may be given in larger doses than the tincture of iodine. If we dissolve a drachm in an ounce of distilled water, we may begin with ten or fifteen minims, and increase the dose to a great amount. There were two or three men whom some gentlemen of my class saw at St. Thomas's Hospital, and who took two drachms of the salt at a time. There can be no doubt that the medicine was good; for Dr. Burton\* analyzed it very carefully. The article is often adulterated; and lime has been found in it; but care was taken to have a good article; and that which these men took was known to be a pure salt. I also recollect a woman, who took one drachm for a dose, three times a day, diluted with ten or fifteen ounces of distilled water. There is no rule for any medicine, as to the dose applicable to all cases. Some persons always find fault with others who are energetic, or employ remedies in an efficient manner; but it does not follow, because we are energetic, and employ medicines *efficiently*, that we should employ them *rashly*. There is no occasion to do a patient harm; and no occasion to run any risk. It has been thought by some, that it would be better to give iodine and this salt together.

With respect to the length of time during which the remedy may be taken, I have been obliged, in bronchocele, to give iodine a whole year, before the disease was cured. Seeing the disease was lessened, I persevered; and have gone on for twelve months; and, indeed, for more than that time. I think, in one case, I continued the remedy fourteen or sixteen months, before the disease went away. That was the longest case of bronchocele I ever cured. I never saw any unpleasant constitutional effect; though no doubt such effects will occur, for they have been mentioned by authors; but I think if we see the patient frequently, and make proper inquiries at every visit, such unpleasant effects can hardly take place. Now and then, it may take us by surprise; as is the case with every remedy. It may act suddenly. But in general, when a remedy *appears* to act suddenly, it has been continued some time after its effects have begun; and if it had been watched carefully, and left off the moment it commenced its action on the body, no such effects would have ensued. In cases where a remedy has seemed to act suddenly, I cannot but think that, with the exception of digitalis, it has generally begun to act mo-

\* At that time, the Lecturer on Chemistry at St. Thomas's Hospital.

derately, and has then been continued without diminution. Had it been omitted the moment the effect began, the slight effect would gradually have ceased. I am not aware of ever having done mischief with iodine.

*External Use of Iodine.*—It is well to apply the remedy *externally*, as well as *internally*. We make an ointment by putting a drachm, or even two drachms of the hydriodate of potassa, to an ounce of lard. The skin differs like the mucous membrane, and the constitution at large; and what produces merely an irritation in one part, will produce a diffused rash in another. It is well to use half a drachm, or a drachm at first, if the person have a fine skin; and then, if no ill effect be produced, we can increase it. It is absurd to apply it so as to irritate the skin. The patient cannot bear rubbing then; and if inflammation begin, it must cease before we can apply it again; and we lose so much time. We shall see, when I speak of diseases of the abdomen, how much good is effected in the same way as in bronchocele, by the exhibition of this medicine.

*Other Remedies.*—Besides burnt sponge and iodine, some recommend carbonate of soda; some, conium; and some, leeches. If the part fall into an inflammatory state, leeches may be useful; and if inflammation occur, the iodine should be suspended, and common aniphlogistic remedies resorted to, till the effect has ceased; and then it should be had recourse to again. Mercury, internally and externally, has been useful; and the two may be combined. I have seen the disease give way to the two; but I can hardly say how much good was ascribable to each. Pressure has been said to be useful; but it is awkward to make pressure, on account of the trachea and œsophagus. There can be no doubt that a seton, in this disease, is an efficient remedy. There are on record, very many cases of this disease, which have yielded to a seton placed in the skin over the tumour.

*Ligatures on the Vessels.*—The disease has been treated *surgically*, as well as *medically*. Some surgeons have tied the vessels of the tumour, with good effect; but this is a point on which I must not dwell. I have only to do with this disease as it is treated by medicine; but I may mention, that Sir William Blizard (formerly an able surgeon at the London Hospital) tied the vessels; but death took place from secondary hæmorrhage. However, in one week the tumour decreased in size one-third. Walther tied the left inferior thyroideal artery; and the tumour diminished so much, that at the end of fourteen days he took up the right superior thyroideal artery. No inconvenience was felt; and the tumour speedily disappeared almost entirely. A surgeon in this country (Mr. Coates) tied the artery on the left side only; and cured the complaint.

*Extirpation of the Gland.*—Some surgeons have been bolder still. Dr. Hedenus, of Dresden, (with whose son I was acquainted,) extirpated the gland in six cases; in one of which it was as large as a skittle-ball. The whole of the cases were successful. Foderé mentions the case of a barber, who cut one away from his wife. This was a lucky hit; for he would probably kill the next woman on whom he operated. Two unsuccessful cases of extirpation, are said to have occurred to Mr. Gooch. Dupuytren (the celebrated French surgeon) removed a tumour, after having first tied the arteries. Only a few spoonfuls of blood were lost; but the operation was very long. Much suffering took place; and the patient died in thirty hours. In several cases, the operation has been found so hazardous, and altogether so difficult, that the surgeon has been obliged to desist in the midst. Desault is said to have removed half the gland with success. I find a note in "Frazer's Journal," stating, that in no part of the world has the whole tumour been extirpated. There can, however, be no doubt of the fact; for persons have shown that the tumour has been extirpated, by the scars in the neck left after the operation.

The chief treatment, however, is by means of iodine internally, and a seton. Neither of these will cure every case. I have seen the tumour so hard, that it was quite absurd to suppose any thing was capable of removing it. When it is cartilaginous, or ossified to a great extent, I should think it vain to give iodine, or apply a seton.

## CHAPTER II.

## AFFECTIONS OF THE MOUTH AND THROAT.

## SECTION I.—PAROTITIS.

THE next disease which I shall describe, is an affection of one of the glands in the neighbourhood of the thyroid; but a little higher. This is entirely a medical disease; and I believe the surgeon never applies his art to it. The last-mentioned disease is disputed territory;—surgeons take it, and physicians take it; but this (“the mumps”) is, I believe, strictly medical.

*Definition.*—As this is an inflammation of the parotid glands, it is called “parotitis;” or, in the language of Cullen, “*cynanche parotidea*.” Dr. Cullen describes five kinds of *cynanche*.<sup>a</sup> The definition of the whole is—“pyrexia, frequently of the typhoid type; redness and pain of the fauces; deglutition and respiration difficult, with a sense of constriction; narrowness in the throat.” The first of the five kinds here mentioned, is inflammation of the parotid glands. I think it better to drop the word “*cynanche*,” and not consider the different species of *cynanche* as varieties of one general affection; but I shall speak particularly of inflammation of the *parotids*, inflammation of the *tonsils*, and so on; and I presume that, in a few years, the word “*cynanche*” will be discontinued; and that we shall speak only of diseases of *one* part, or of *another*.

*Symptoms.*—Parotitis, or (in plain language) “the mumps,” is a swelling of one or both parotid glands: attended with an increase of heat in the part; extending to the submaxillary and sublingual glands; and affecting the rest of the salivary glands. The disease is attended by slight feverishness; and lasts, in general, three or four days;—sometimes longer. It is sometimes followed by inflammation of the testicles, or breasts; and sometimes by phrenitis. When a testicle has been so inflamed, it frequently becomes atrophied; and nothing is left but the membranes;—the “*tunica albuginea*,” and “*tunica vaginalis*.”

*Is it Contagious?*—Parotitis occurs, usually, but once during life; and is said, I know not how truly, to be contagious. It certainly is sometimes sporadic; but frequently it is epidemic. It prevails, in a boy’s school, all at once throughout; and it prevails in several schools in the same neighbourhood. I really do not know whether it is so or not.

*Age at which it occurs.*—It occurs most frequently from seven to fifteen years of age;—sometimes later. Now and then, we see it in young men; but most frequently it occurs at the time I have stated.

*Treatment.*—There is nothing particular required for it. We ought to apply moderate warmth, keep the patient quiet, make him abstain from ordinary nourishment and stimuli, give him a mild aperient; and the disease, for the most part, goes away after a time. It is very rarely that suppuration takes place. I have seen suppuration; but I presume it was an accidental circumstance,—from the inflammation extending to the cellular membrane. I should not recommend cold to be applied; because the disease has a tendency to metastasis. At least, when it ceases, the testicles and breasts are apt to be affected; and one would suppose that if we cause it to cease suddenly, there is a greater probability of such inflammation occurring. As to inflammation of a testicle, that is not in itself dangerous. It is only sharp and painful; yet it is thought to be a serious matter. I believe, that if one testicle should be lost, the other will do double work. But there is something

<sup>a</sup> Dr. Cullen’s five species are:—1. Tonsillaris. 2. Maligna. 3. Trachealis. 4. Pharyngea. 5. Parotidea.

more dangerous; and that is the liability to phrenitis. Phrenitis sometimes takes place, when inflammation of the testicle ceases. Sometimes the inflammation in the brain may occur at once, when the mumps cease; but, more frequently than not, inflammation of the breast or testicle occurs *first*, and *then* phrenitis supervenes.

If the case be severe, we must treat it still more actively,—by means of leeches and purgatives.

## SECTION II.—TONSILLITIS.

We now enter the air-passages; and the first disease I shall describe, is inflammation of the tonsils; called by Cullen "*cynanche tonsillaris*," but frequently called by others "*tonsillitis*."<sup>a</sup>

*Symptoms.*—The disease to which these names are given, is not an inflammation of the tonsils simply; for the surrounding parts are more or less affected. The "*velum pendulum palati*" and the uvula, as well as the tonsils,—one or both,—are red and swollen. The uvula is elongated, and its margins are translucent;—it becomes œdematous and swollen. If both tonsils be inflamed, on opening the patient's mouth two large red balls are seen, one on each side of the throat; which impede deglutition and speech. They may also be felt externally. When the tonsils are enlarged, people say "the almonds of the ears are down;" for the tonsils are called, in common language, "the almonds of the ears." Besides this swelling and redness, the secretion of the parts is altered; so that the mucus of the month is very tenacious,—slimy, as people say. There is frequently very great pain; for the inflammation affecting the tonsils is of a phlegmonous character; and the pain is sometimes very severe,—stabbing and shooting to the ear. Besides the shooting pain, there is necessarily great tenderness felt—particularly on swallowing. Even the effort to swallow the saliva—that is to say, the mere effort of swallowing, without the presence of any firm substance to swallow—gives pain; the motion of the part is painful. The disease sometimes occurs on one side only; and it is said that the disease will shift from one tonsil to the other;—as in inflammation of the eye. When one eye gets better, the other may become inflamed; and a similar occurrence often takes place in the case of the tonsils; when one ceases to be inflamed, the other becomes so.

Sometimes, in addition to the redness, heat, swelling, and hardness, there are specks of ulceration. Some persons, as soon as they have a sore throat, have specks of ulceration here and there, on the tonsils and uvula; with very little sub-jacent inflammation. Some persons have the mucous membrane inflamed alone; without any inflammation of the subjacent cellular membrane, hardness, or enlargement. If the case be severe, there is a good deal of pyrexia. The pulse will become very quick in this disease, (as it sometimes will in acute rheumatism,) without any danger whatever; and the tongue is frequently excessively foul;—I presume from the inflammation affecting it, as well as other parts. The foulness of the tongue is not at all in proportion to the danger of the disease; but I presume it arises, in a great measure, from the irritation being situated in that quarter of the body.

*Terminations.*—The disease may terminate in "resolution," as it is called; or it may terminate in suppuration. It is decidedly phlegmonous inflammation, so far as the parts are concerned; and they very frequently suppurate; and when they do, the matter is found to be very offensive;—as offensive as if it were coming from a diseased bone.

*Causes.*—The *predisposing* causes of the disease are, in the first place, a peculiar constitution, and disposition to it. There are some people who, in whatever way they may be exposed to the general causes of inflammation, continually get a sore-throat. Whenever they are exposed to the vicissitudes of temperature,

<sup>a</sup> From "*tonsillæ*," the tonsils; and "*itis*," inflammation.

coldness, and moisture, they are sure to have inflammation of the throat; and this will run in families,—so as to be constitutional. It certainly is predisposed to by mercury. When persons have been much under the influence of mercury, they are very liable (as I mentioned when speaking of inflammation in general<sup>a</sup>) to take cold from the vicissitudes of temperature; and the throat is certainly particularly liable to inflammation from this cause. The youthful period of life appears more liable to tonsillitis than old age; for we see far more cases of inflammatory sore-throat in the young, than in the old. Perhaps, among the predisposing causes, I might mention the season of the year;—Spring. Cases of this description certainly occur (from cold and wet) more frequently in the Spring, than at any other period.

The *exciting* causes of the disease are, especially, cold and wet;—whether applied to the body at large, or to the feet only. Cold applied in any way, is sufficient to produce the disease.

*Treatment.*—It is rarely necessary to take blood from the arm; but leeches around the throat are particularly useful. I do not know that it is necessary to apply them internally to the fauces. I think that, applied *externally*, they answer every purpose they can effect; and that a free application of leeches, is far superior to blistering. As a general rule, in the treatment of inflammation, we must be upon our guard never to let blistering take the place of the removal of blood. If the inflammation be at all severe, and requires the abstraction of blood, we only harass a patient (in any disease whatever) by blistering; which, in this disease, is a very painful remedy, and does not, by any means, answer so good a purpose as the frequent application of leeches externally, under the lower jaw, followed by poultices. The latter not only tend to encourage the bleeding, but act as a constant fomentation;—relaxing the parts, and causing perspiration there. If the patient be too weak for the application of leeches, a blister then will be proper; or, if we have applied leeches as far as it appears advisable, and still it is requisite to do more before the disease can be controlled, then blisters may be used with advantage. It must be remembered, however, that when a patient can bear leeches, they are the most useful remedy.

*Incision of the Tonsils.*—I have found great benefit, in this disease, from a mode of treatment perfectly analogous to what is practised, with so much success, in some cases of inflammation of the surface of the body, and subjacent cellular membrane. In “erysipelas phlegmonodes,” or any kind of erysipelas where there is extreme tension and hardness of the surface, incisions do great good. They set the surface at liberty; so that the tension is removed, and great benefit always ensues.<sup>b</sup> Now I have adopted similar treatment, frequently, in inflammation of the tonsils; and with very great effect. It is sometimes very difficult to know, in the case of the tonsils, whether matter is formed or not; and I dare say many practitioners (I am sure it has occurred to me) have plunged a lancet into the tonsils, in the expectation of finding matter, when there was none. They sometimes become so exceedingly large, that it warrants a person in trying whether there is any matter or not. Sometimes, when there is matter, instead of being softened, the parts are so tense that we do not find any fluctuation; and sometimes they are swollen so much, that we might fancy there was fluid when there is not. Thus mistakes are made on both sides. But whether matter comes or not, great relief is experienced by plunging a lancet into one or two places. The part is always very tense, and if incised by a lancet, gapes; and when there is a little bleeding, the patient (in most cases) is better for it. I have seen it afford far more relief than leeches; and I know, therefore, that it is a very good practice. If there be any matter there, its escape is desirable; but even if there be none, we generally find very great benefit. It is wrong to delay this operation; for it is quite harmless, and productive only of momentary pain.

*Purging and Vomiting.*—For the purpose of purging, there is nothing so good as a large dose of calomel; because it may be mixed with sugar, and put on the

<sup>a</sup> See Page 112.

<sup>b</sup> See Page 401.

tongue; when it slips down easily. It is wrong to give acrid purgatives, such as salts, which stimulate the parts as they go down; and it is wrong to give any thing bulky. Castor oil easily slips down. Some persons recommend vomiting, in this disease; and it certainly causes a great discharge of mucus from the pharynx and larynx, and all the surrounding parts; and frequently does good; but, frequently, it is a severe remedy.

*Gargles.*—Gargles are pleasant to the patient, on account of the tenacity of the mucus. A sour gargle is very grateful; and so, sometimes, is the inhalation of the steam of hot water. This relaxes the parts, and is found very agreeable; but I have often seen patients derive the greatest comfort from ices.

I believe the free application of leeches externally, an incision or two in the tonsils, and a good dose of calomel will, for the most part, cure the disease. As to starving and low diet, we need not *inculcate* that; for the patient cannot swallow any thing.

*Tonsillitis with Debility.*—Although the above described form of the disease is that which we see every day, yet we occasionally find this affection occurring with debility. It is chiefly in old people that it occurs in this latter form; and chiefly in people who have had frequent sore-throats. When the throat has been sore very often, the inflammation is not of an active kind, but follows the course of gonorrhoea. When people have had the latter affection very often, the active symptoms are less severe; and so it is in the throat. When persons have had many attacks of tonsillitis, the inflammation is generally less active: the parts are not of so bright a red; they are of a more *dingy* red; there is less pain; and the swelling is greater in proportion to the other symptoms. In such a case as this,—with such debility of constitution, the shortest way is to give stimulating gargles;—for instance, the decoction of seneka, with Cayenne pepper and brandy in it. If the patient be weak, we must give good food; and sometimes allow a little wine. The case may be (like any other inflammation) *active*, and to be treated as first pointed out; or it may be *passive*, and require only local astringents and stimulants. But sometimes the whole constitution is weak; and we have to support the patient with good food, and perhaps even wine.<sup>a</sup>

*Ulceration and Gangrene.*—Sometimes, when the disease occurs with ulceration, there is a great tendency to mortification. This is a case that must be treated on the principles I before mentioned;<sup>b</sup>—good food, more wine, and perhaps quinine. But good food and wine, are among the best things; and we must also employ stimulating applications, together with stimulating gargles. In this case, too, the chlorides of soda and lime answer very well;—that is, when the patient simply requires a stimulating gargle.

We are not, however, in every case of inflammation, to presume the existence of ulceration; but (as I mentioned when speaking of ulceration of other parts of the body) where there is ulceration, we must adopt the antiphlogistic regimen.<sup>c</sup> Many cases of ulcers of the leg yield to antiphlogistic treatment, after all other means have failed; and so it is in ulceration of other parts of the body. The parts are red, and there are signs of strength; and the shortest way to cure the ulceration is to bleed locally and generally, and put the antiphlogistic plan in force. Ulceration occurring in the throat, however, is most frequently of an opposite character. This ulceration of the throat is most frequently seen in scarlet-fever; where it is called "*cynanche maligna*;"<sup>d</sup> but ulceration of the throat frequently occurs without scarlet-fever at all. In these circumstances, it is frequently necessary to inject stimulating gargles, several times a-day. There are many good applications, but one of the best is the acetate of copper, made into a gargle.

*Chronic Ulceration.*—Chronic ulceration of the tonsils is also very common; being one of the common effects of syphilis.

*Enlargement of the Tonsils.*—Inflammation of the tonsils is sometimes chronic; and is then attended with permanent enlargement of the tonsils. This is more

<sup>a</sup> See Page 131.    <sup>b</sup> See Pages 130 and 131, and 134.    <sup>c</sup> See Page 134.    <sup>d</sup> See Page 390.

frequently seen in children than others. The tonsils, after they have been inflamed, remain hard,—fall into a state of chronic inflammation, induration, and enlargement;—from lymph, I presume, having been effused into the cellular membrane. There is no difficulty, in cases of this description, in making a diagnosis. If we fail to make it externally, we have only to make the patient open his mouth, and the disease is apparent. The best treatment is the moderate exhibition of calomel, so as slightly to affect the mouth; the use of iodine, internally or externally; and of hydriodate of potassa. Iodine, in both forms, has great power in dissolving and dissipating induration and enlargement. There can be no impropriety in combining both plans. If there be much tenderness, leeches are very proper.

Occasionally this enlargement is not the result of *active* inflammation, but takes place *slowly*; and friction with iodine, or hydriodate of potassa, or both, is a very good thing. Sometimes there are cases, in which it is judged right to have recourse to surgery; to extirpate the tonsils, or tie a ligature; but the greater number of cases do not require this, provided they are treated early and perseveringly by mercury, or iodine and hydriodate of potassa, both internally and externally.

*Pharyngitis*.—Cullen also speaks of inflammation, very far back in the throat; and I therefore legitimately touch upon it. I allude to “pharyngitis,”—inflammation of the pharynx; or, as it is called by Cullen, “*cynanche pharyngea*.”

*Symptoms*.—Pharyngitis usually takes place from the mere spread of inflammation from the tonsils. When the tonsils are inflamed, it is very common for the inflammation to go farther back. Inflammation knows nothing of our artificial division of organs, and division of diseases; but spreads along the mucous membrane; and the pharynx is continually becoming inflamed. Now and then, however, it occurs in an *idiopathic* form;—that is to say, it occurs as a distinct separate disease. I have seen one or two instances of it. When this inflammation exists, there is redness at the back of the throat. On looking into the mouth, we see the posterior part exceedingly red. Deglutition is very much impeded; but respiration is not at all difficult. At any rate, if there be any difficulty of respiration, it is slight. The voice is not affected, any more than respiration. It is the gullet that is affected; and therefore persons can speak and respire very well.

The *treatment* of this affection is the same as that for inflammation of the tonsils; and therefore I shall not dwell upon it.

### SECTION III.—STRICTURE OF THE ŒSOPHAGUS.

We are frequently consulted upon a disease, which occurs rather lower down than the pharynx. I refer to stricture in the œsophagus,—producing obstruction.

*Symptoms*.—In this disease there is, as in inflammation, a difficulty of deglutition; but then there is no sensation of heat in the part,—no soreness;—and, for the most part, no pain. The difficulty of deglutition is chronic; and, for the most part, has come on very slowly. It is easily ascertained by the application of a bougie or probang; and this, I may say, is the only remedy; for medicine can do no good in stricture of the œsophagus. When patients come to us with a difficulty of swallowing, if we ascertain it is not in the throat, but a little lower down, and that stricture has come on slowly, it is right to pass an instrument down a certain distance. This being the case, we employ surgery, and surgery only.

*Spasmodic Stricture*.—But this disease appears sometimes in a different form; and it is then entirely of a *spasmodic* nature. Frequently, when persons have not a *permanent* stricture of the œsophagus, they have occasionally a *spasmodic* stricture in the part;—just as they have in the urethra; so that it will be much worse at one time, than at another. This occurs more frequently in women, than in other persons; and frequently it is connected with hysterical symptoms.

*Treatment*.—The best mode of treating it, is to use the shower-bath; to purge

\* See Page 692.

the patient well; and to use oil of turpentine, and other remedies of that kind. I have read of cases where it appeared to give way to mercury; but I have not seen them myself. It has always appeared to me, that they would do better with the common remedies of hysteria;—by purging, on the one hand; and by lessening the irritability of the body at large, (by means of the shower-bath, the administration of iron, and putting the health generally into good order,) on the other. We must carefully remember this form of the disease, and its freedom from danger.

#### SECTION IV.—INFLAMMATION OF THE MOUTH (STOMATITIS).

##### *a. Pustules of the Mouth.*

*Characters.*—Repeatedly are children brought to us by their mothers, with pustules on the tongue and lips, and inside the cheeks. I do not know that the disease has any specific name; but the parts I have mentioned, are elevated in consequence of the pustules; and the tongue is frequently much swollen, and just the colour that it is when persons are much under the influence of mercury. From the swelling of the tongue, the quantity of mucus secreted, the saliva running out of the mouth, and the fetid state of the breath, one would imagine, at first sight, that the child had taken mercury; but if we give calomel in such a state, it does not increase the mischief, but answers well as a purgative. It is one of the best to give children.

*Treatment.*—I have found great benefit, in these cases, from the use of washes containing some astringent; but the mode of giving it to the child, is to put a grain or two of sulphate of zinc (for example) into an ounce of syrup. The child has no objection to it; and it exercises a beneficial influence. The disease sometimes occurs to many children in one family; but whether it is contagious I do not know. The disease is described as common ulcers in the mouths of children; and they may last some time without any danger; but purgatives and local astringents are very useful. Whenever we have to apply an astringent to the mouth of a child, it is better to give it in syrup, instead of water.

##### *b. Aphthæ.*

There is a disease that frequently affects the mouth, and neighbouring parts; and usually in the period of infancy. It is called the “thrush;” or, in medical language, “*aphthæ*.”<sup>a</sup> It is always mentioned under diseases of the skin; but as it occurs in the mouth and throat, it is perhaps hardly right to call it “a *cutaneous* disease;”—it is a disease of the mucous membrane.

*Characters.*—It consists in the formation of vesicles within the mouth and lips, and all the way along the cheeks, the tongue, and the *velum pendulum palati*; and even on the mucous membrane of the hard palate, the tonsils, and pharynx. On opening the mouth, it presents an appearance just as if the patient had been taking milk, curds and whey, or some chalk mixture;—all the vesicles are exceedingly white. This is produced by innumerable elevations of the cuticle, by a fluid, and a large number of minute vesicles. There is sometimes a good deal of inflammation with it; and sometimes there is scarcely any thing more than this white appearance,—as if the parts were filled with curd.

*Age at which it occurs.*—This disease is certainly most common in infants; but we shall frequently see it in adults, at the end of chronic diseases;—at the end of phthisis, for instance. It is very common then for persons to complain much of the throat;—to complain of a difficulty of swallowing; and even when persons die of diseases of the abdomen, of various sorts, it is very usual indeed to see aphthæ before death. It will occur in old people from very trifling causes.

<sup>a</sup> From *απτν*, to set on fire.

*Not necessarily fatal in Old Age.*—It is supposed to be a fatal disease, when it occurs in old people; or in those in whom a chronic disease has existed for a long time; but it is not an invariable rule. I recollect an old lady of ninety, who at that advanced age, suffered an attack of bronchitis, and got well;—and afterwards attained the age of one hundred;—how much more I cannot tell; but I know she lived ten years after the attack, notwithstanding it was united with aphthæ; and therefore aphthæ is not necessarily a fatal sign in old people. We see the disease every day, however, in persons who are dying of chronic diseases. I believe old women say, that if we do not have it when we are *young*, we must have it when we are *old*. I only mention this to show how common the disease is.

*Treatment.*—When the disease occurs in infants, it may be so slight as to require scarcely any treatment; but if it do, we find it useful to employ the warm bath, and attend to the bowels. There is frequently irritation of the mucous membrane lower down in the alimentary canal; frequently sickness and diarrhœa; and therefore it is sometimes useful, besides the warm bath, to have recourse to purgatives; and besides that, it is sometimes necessary to employ Hydrargyrum cum Cretâ, and opium. There is often tenderness on pressure; and then it is necessary to apply poultices over the abdomen, as a constant warm bath; and to apply a leech or two; but often a mustard poultice answers best. A small portion of ipecacuanha or camphor, is often serviceable; but nothing is better than a mild astringent in syrup;—such as I have mentioned already\* (made with a minute quantity of sulphate of zinc). Many people employ borax and honey; and injudicious nurses tie a rag to a stick, and mop out the child's mouth; and thus make things worse. They had better use a camel's-hair pencil; or leave the disease to pursue its course. I have no doubt that the chlorides are useful; but in the case of children, they must be given very much diluted. In adults, I do not know any means so useful as the chlorides. They will frequently change the appearance of the mouth almost immediately; but the common solution must be diluted with six or eight times its weight of water. When the intestines have been in a state of irritation only, a few specks will appear at the rectum; and then old women consider that the disease has had a long journey, and has shown itself at the other end. If, however, we examine the intestines, we find no inflammation,—only specks; and it is only towards the anus that these specks appear. Nevertheless, the irritation which produced the vesicles, certainly does frequently extend all through the alimentary canal.

### *c. Stomatitis Mercurialis.*

[The inflammation of the mouth excited by the specific action of mercury, is a serious adjunct to the *ptyalism* produced by this metal. "Ptyalism" strictly signifies increased secretion from the salivary glands; and it may occur quite independently of mercurial action, as an accompaniment of hysteria, hypochondriasis, and dyspepsia; but it is then very rarely attended with stomatitis.

*Symptoms.*—The affection is generally preceded by an unpleasant taste, compared to that of copper or brass; soon after which the patient complains that his teeth feel soft and tender when brought together, and he fancies they are loosened in their sockets. Soon after this, shooting pains are felt in the face, and a stiffness in the movement of the lower jaw, caused by tumefaction of the submaxillary and parotid glands. The gums are of a deep red colour, and their margins projected (as it were) from the teeth. Here and there we may perceive spots of a dull whiteness, caused by opacity of the epithelium. The tongue is swollen, indented at the edges by the pressure of the teeth, and coated with a thick yellow or brownish fur: the breath has a peculiar fetor, and often before the stomatitis is very manifest. In severe cases there is ulceration of the gums; commencing at the margins, and extending to the interior of the cheeks. Occasionally the tumefaction of the salivary

\* See Page 695.

glands is so great, as to prevent the mouth from being opened: this, together with the engorgement of the tongue, may become so considerable as to induce suffocation. But without attaining so serious a degree, the stomatitis is productive of great distress, by the impediment to speaking, mastication, and deglutition, as well as by the profuse secretion of saliva. The patient often complains of it more bitterly than of the internal inflammation, for the removal of which the mercury was administered; and he can scarcely refrain from inveighing against his physician, for substituting so loathsome an affection even for a malady which threatened his existence. The local symptoms are generally accompanied by feverishness, and general irritation.

*Duration.*—The duration of pytalism varies with the extent and severity of the inflammation. If ulceration has taken place, the parts seldom recover themselves till several weeks have elapsed; and even without this, it may be almost as long before the spongy state of the gums, and the increased flow of saliva, entirely subside. Ordinarily, however, when there has been only turgescence and soreness of the gums, the affection disappears in a few days.

*Modifying Circumstances.*—The severity of stomatitis holds no direct ratio with the amount of the mercury introduced into the system. The enormous quantities requisite for inducing the specific effects of this metal in some subjects, are no less surprising than the sudden appearance of the affection, when only the most trifling doses have been taken. Some persons have, by idiosyncrasy, a remarkable susceptibility of mercurial influence; while others are as strikingly capable of resisting it. The constitutional liability, however, cannot be fairly estimated when inflammatory disease is present; for the most general fact with which we are acquainted as to the specific action of mercury, is, that the readiness with which it takes place is in an inverse ratio with the intensity of the existing disease. Other circumstances, also, very materially affect the result; such as the mode of administration, the state of the bowels, and of the function of the skin, previous blood-letting, &c.; but this is not the place for their consideration.

*Treatment.*—In slight cases, very little more is necessary than to enjoin frequent ablution of the mouth, at first with tepid water, and afterwards with a mild astringent gargle; and to secure a free action of the bowels by saline aperients, and of the skin by warm clothing. When the inflammation is more severe,—as indicated by a white line of suppuration along the edges of the gums,—we must, in addition to the measures just mentioned, employ others of greater activity. If the tumefaction is general, leeches applied under the lower jaw, with fomentations, will afford relief. The best local application (in our experience<sup>a</sup>) is the nitrate of silver, either in substance, or in a strong solution (two scruples to an ounce of distilled water), by means of a small sponge fastened to a proper handle, or a camel-hair pencil. A lotion of chloride of soda will be very useful for correcting the fœtor, as well as for its stimulant property. An alum-gargle containing laudanum is of service, when the active period of inflammation has passed by. We<sup>b</sup> have very little confidence in internal medicines exhibited as antidotes; such as sulphur and iodine. The supposed efficacy of the former depends, we<sup>b</sup> believe, on its laxative operation. Opium in repeated doses has proved useful by quieting the erethism;<sup>c</sup> and also, perhaps, by lessening the secretion from the salivary glands. But it must be confessed, that the affection is very slightly amenable to treatment, excepting as to the progress of ulceration; which may be arrested, with tolerably certainty, by the nitrate of silver. The practitioner should never neglect to enjoin free ventilation of the patient's apartment; which, indeed, ought to be kept not only airy, but cool.

#### *d. Stomatitis Ulcerosa.*

*Symptoms.*—Under this term we shall notice a form of inflammation of the

<sup>a</sup> That of Dr. Symonds.

<sup>b</sup> Dr. Symonds.

<sup>c</sup> From *ερεθισμός*, to excite.

gums, which appears in children between the first and second dentition. It is sometimes called "cancrum oris," or a milder variety of that frightful disease which we shall describe presently, under the appellation—"gangræna oris." It would be better to confine both these terms to the latter disease; which is not merely more intense in degree, but distinct in its pathological nature, from "stomatitis ulcerosa." This affection begins with inflammation of the outer surface of the gum, and more commonly in the lower jaw; sometimes limited to one side, but more frequently extending to both sides. The inflamed part is extremely swollen, and soon surmounted by a line of ulceration at the margin adjoining the teeth. The cheeks and lips became hard and cedematous,—so as to impede the opening of the mouth; and this, together with the quantity of mucus and saliva collected between the gum and the cheek, renders it difficult to procure a satisfactory inspection of the diseased parts. The breath has a peculiar fœtor, allied to the state called "brassy" or "coppery," and quite distinguishable from the odour of gangrene.<sup>a</sup> There is often considerable flushing of the face and conjunctivæ, with heat and tenderness; and the glands below the jaw are enlarged and painful. If the disease be not speedily checked, the ulceration may proceed so far as to lay bare the alveolar processes; but, occasionally, we have known it continue in an indolent state for several days, neither advancing nor disposed to heal. In some subjects, the ulcerated surface is very prone to bleed. More or less fever, for the most part, accompanies the affection; but is sometimes absent. The bowels are costive, and there is no inclination to food.

*Causes.*—The disease prevails chiefly among the poorer classes of the community; and indicates debility of habit, as a predisposing cause. The attack may be often referred to the immediate agency of cold, damp, or disorder of the stomach and bowels. When seen early, the prognosis is favourable; unless the disease has supervened upon some other acute malady;—such as fever or scarlatina.

*Treatment.*—Though the disease is inflammatory, it is not to be combated by the ordinary antiphlogistic measures. Leeches and cold lotions may be useful in reducing the glandular enlargements; but they cannot be depended upon for stopping the internal ulceration. The best applications for this purpose, are of the same kind as we have recommended in the other species of stomatitis;<sup>b</sup>—such as the strong solution of nitrate of silver, and the mixture of syrup and sulphate of zinc. A linctus made with a drachm of strong muriatic acid, added to an ounce of honey, is an excellent remedy. We can also speak highly of a gargle composed of alum, decoction of cinchona, and tincture of myrrh. The only objection to this (as to certain other gargles) is, that the age of the child often prevents it from being used in sufficient quantity, or with sufficient frequency, to render it efficient.

The internal treatment may be commenced by an emetic; unless the lips and cheeks are so swollen and tender, as to render vomiting too distressing an action. After the emetic, a brisk purgative of scammony or jalap, with calomel or Hydrargyrum cum Cretâ, should be administered. If there is much fever, we may exhibit salines and antimonials; but it is seldom necessary to continue them longer than a day or two. The action of the bowels may be maintained by castor oil, or rhubarb and soda. Should the ulceration, after the above treatment, show a tendency to spread, we must exhibit the sulphate of quina, or decoction of bark, in doses suited to the age of the patient;—continuing, at the same time, the local treatment with undiminished energy.

## SECTION V.—GANGRÆNA ORIS.

*Synonymes.*—Gangrene of the mouth may be the consequence of any of the forms of stomatitis; but the disease we are about to consider is idiopathic, or gangrene proper;—beginning with that loss of vitality which, in inflammatory morbi-

<sup>a</sup> See Page 99.

<sup>b</sup> See Page 697.

cation, is the last of a series of morbid changes. The synonyms of "*gangræna oris*" are—"cancrum oris," "*sloughing phagedæna of the mouth*," "*water-canker*," "*stomacace maligna*," "*norina*," "*necrosis infantilis*."

*Symptoms.*—The existence of this disease is generally first intimated by an indolent swelling of one cheek, without heat or redness. It is hard to the touch; and so little tender or painful, that the patient seems all but unconscious of it; and, but for the enlargement being obvious to the eye, the mischief would probably escape notice altogether in its early stage. Indeed, as it is, the tumefaction is occasionally mistaken for affections of a much less serious description. The skin of the cheek has a peculiar glossy or waxy appearance. On examination of the mouth, we detect a whitish or ash-coloured eschar, without any inflammatory redness of the surrounding membrane; generally in the centre of the cheek, or in the commissure of this part and the lower jaw. The gums look pale and spongy. There may be a certain degree of languor, dulness, or slight feverishness; but, not less frequently, there is nothing to call particular attention to the general health. Such are the principal phenomena of the first stage of the disease. As it advances, the slough spreads rapidly over the interior of the cheek and lip, and invades the gums. Saliva escapes in great quantity: at first clear, afterwards mixed with a dirty sanious matter, which has a horrible fætor. About the same time, the outside of the cheek presents a pale ashy spot; which soon becomes livid, and sphacelates. The extension of the disease to the bony structures, is evidenced by the loosening of the teeth; which are soon thrown off, with portions of the alveolar processes. The fluid discharged appears to have a corrosive quality; for the angles of the mouth and the lower lip sometimes become new centres of mortification. We<sup>a</sup> have known both sides of the face attacked in the same individual; and there are cases on record in which all parts of the face, as well as the upper maxillary bones, the palatal, the nasal, and even the ethmoid, were involved in the destruction. Usually, however, death prevents the lesion from extending so widely.

The constitutional disturbance is, in many cases, far from being proportionate to the severity of the local affection. The pulse is frequent, but weak; the bowels, at first confined, become, towards the close of the malady, extremely relaxed; and the heat of the extremities is much depressed.

*Causes.*—The subjects of "*gangræna oris*" are children, usually between two and five years of age; but we<sup>a</sup> once met with it in a girl who had attained her eighth year. It is confined to children of debilitated habit, and is very rarely observed among the richer classes; low marshy situations, and rainy seasons, appear to increase the predisposition. Not unfrequently, "*gangræna oris*" is one of the sequelæ of exanthematous fevers. There is no good reason for attributing the disease to the specific action of mercury; though it may have sometimes supervened upon the latter; which, like any other cause of derangement, may have given the first impulse to the morbid process. It has often occurred when not a particle of mercury had been administered.

*Pathology.*—As to the pathology, we<sup>a</sup> have already expressed our belief,<sup>b</sup> that the disease is gangrenous *ab origine*. Any inflammation that may be found about the part is secondary only;—bearing no causative relation to the gangrene. It has been stated, that the commencement is often unattended by pain, heat, or redness. The swelling is the effect of the retarded circulation in the capillaries, and the infiltration of the tissues with serum, or "*liquor sanguinis*." The pressure thus produced, is sufficient to explain why the vitality of the central portion is destroyed. The mortification extends by contiguity; because the capillary circulation in the adjacent parts, is necessarily affected by the pressure of the diseased tissue. If they have sufficient vital action, they may only suffer inflammation and suppuration; but it too often happens, that the lesion assumes the same character as in the neighbouring part;—being influenced by the same state of the general habit. It can scarcely be doubted, that this depraved habit consists mainly in deficient plasticity of the blood. The worst case that ever fell under our<sup>a</sup> notice, occurred in a girl recovering from

<sup>a</sup> Dr. Symonds.

<sup>b</sup> See Page 698.

mild fever, who had been leeches on the forehead. There had been extreme difficulty in restraining the hæmorrhage from the leech-bites;—in consequence of the incoagulable quality of the blood.

*Prognosis.*—The *prognosis* is, from the first, unfavourable. Though the child may escape with life, it cannot be saved from disfiguration, when the gangrene is once established. If however œdema has been discovered very early, and a vigorous treatment adopted, the danger may sometimes be warded off.

*Treatment.*—On the first appearance of the swelling, the cheek should be frequently rubbed with a stimulating embrocation, consisting of camphorated oil and ammonia; and in the intervals should be kept moist with a tepid lotion, containing muriate of ammonia and spirit of wine. A careful examination of the interior should be made; so that, on the detection of the slightest appearance of an eschar, the part may be touched with the solid nitrate of silver, or strong muriatic acid. If sloughing has already commenced, the lotion of nitrate of silver<sup>a</sup> will be the best application. The mouth should be frequently washed out, or syringed, with a solution of chloride of soda;—if only to moderate the fœtor. M. Billard recommends, that as soon as the livid spot on the exterior of the cheek shows itself, a crucial incision should be made into the centre of the swelling, and butter of antimony introduced, or (still better) the actual cautery at a white heat.<sup>b</sup> This remedy had been previously much insisted on by M. Baron. When the gangrene is complete, we must endeavour to stop its extension by fermenting poultices.

The medicines to be exhibited are tonics and stimulants; of which carbonate of ammonia in decoction of bark, or quina combined with camphor, are the most efficient. Wine or brandy may be liberally administered, with beef-tea. Opium is strongly indicated;—not merely for allaying general irritation, but for the sake of the stimulating influence which it is known to exercise upon diseases of the capillary system characterized by debility. Constipation or diarrhœa must be met by the remedies appropriate to either state. The patient should, if possible, be placed in a large airy apartment.<sup>c</sup>]

## SECTION VI.—FETID BREATH.

I may mention that persons sometimes consult us, on account of having a fetid breath; called, in vulgar language, “a smoky chimney.” It must be very annoying if people are married, or in the way of being married, and I have no doubt that it has frequently prevented that interesting ceremony from taking place.

*Causes.*—Fetid breath may arise from many causes. It may be accidental, from a person eating something disagreeable; which enters into the blood, and is poured forth from the vessels of the bronchia, till the blood gets rid of it all. If a person eat onions, it is not while they are in the *stomach* that the breath is fetid; but when the odorous principle of the onions gets into the blood, it is poured forth from the bronchial membrane. The bronchial membrane is found, by physiological experiment, to be one of the great outlets by which the body gets rid of things foreign to the blood. Carious teeth, or a diseased bone, is likewise a cause of fetid breath; but one very common cause is a depraved secretion of the tonsils. On looking into the mouths of these patients, we frequently see the tonsils enlarged, or at any rate containing a cheesy matter. If this be pressed out with the handle of a spoon, the person's breath (for the time) is rendered less offensive. I should imagine, that stimulating the follicles to secrete more abundantly, would favour the escape of this disagreeable matter; and not allow it to accumulate there, and form these nauseous concretions; but the individual's breath itself may be fetid, independently of this offensive secretion.

<sup>a</sup> See Page 697.

<sup>b</sup> “*Maladies des Enfants.*” Page 217.

<sup>c</sup> “*Library of Medicine;*” Volume 4; Pages 36 to 40.

## SECTION VII.—EARACHE.

Before I quit these parts, as we are so near the ear, (which communicates with them by the eustachian tube,) it may be well to notice what is commonly called "earache." It is not, in general, an important disease; but sometimes it is of very great consequence. I mentioned, when speaking of inflammation of the brain, that the latter will spread from the ears and eyes.<sup>a</sup> I have seen several cases of phrenitis, which have spread from the ear. Common earache is not a thing so free from danger as toothache. We see earache very frequently, and are apt to disregard it; but, in any case, it may be dangerous.

Earache always arises from more or less inflammation in the "meatus auditorius;" and ought always to be attended to. Leeches should be applied externally, and blisters; and, in some cases, the patient should be bled in the arm. After it has lasted a long time, the bones frequently become carious; and, when the bones are carious within, inflammation of the "dura mater," lying upon the petrous portion of the temporal bone, is likely to come on; and then it is all over. After death, matter is found within the ear itself; but sometimes also upon the bone, under the "dura mater;" and perhaps *above* the "dura mater,"—in the arachnoid, on the "pia mater," and on various other parts of the head. Encephaloid disease, and other affections, take place; the patient becomes delirious, and is soon gone. Therefore, when intense earache occurs, and the patient complains of pain in some other part besides the ear, and there is a wandering of the eyes, it is well to tell the friends that he is in the greatest danger.

Such a case (like other varieties of phrenitis) ought to be treated actively; but I believe, in almost every case, treatment will be found unavailing. There is a local cause (that is to say, disease of the ear) keeping up inflammation of the part; and therefore we cannot expect to be successful.<sup>b</sup>

## CHAPTER III.

## DIAGNOSIS OF PULMONARY DISEASES.

[A KNOWLEDGE of the condition of the chest and its organs, in health and in disease, is to be obtained by the study of those properties which are signs or indications of this condition. These properties are divided into two classes:—the *physical properties*, which are those capable of directly impressing our senses; and the *vital phenomena*, or those which arise out of the vital endowments of the parts; and which, in combination with physical structure, constitute function. The "physical properties" are necessarily confined to the chest, its contents, and those parts mechanically related with it; but the vital properties" of the chest and its organs affect, and may become evident in, various other parts of the body, through the connecting vital influences of the nervous and vascular systems.

*Physical Examination of the Chest.*—We examine the chest physically by those properties of form, size, proportions, relative position and density of its parts, at rest or in motion, which are within the reach of our senses. Thus we see and feel the shape and motions of the chest; we listen to the sounds which these motions cause, or which may be otherwise produced in the chest,—as by the voice, percussion, &c.; and we judge of the results of these examinations, by comparing

<sup>a</sup> See Page 492.

<sup>b</sup> Full details of the nature and treatment of this and its kindred affections, will be found in a work with which our medical literature has recently been enriched:—"The Nature and Treatment of Disease of the Ear. By Dr. William Kramer. Translated by James Risdon Bennett, M.D."

them with healthy standards. Now it is obvious, that a good knowledge of the anatomy and physiology of the chest, must greatly assist us in this examination; and this knowledge should be especially *topographic*;—teaching where each organ lies and reaches, in relation to the exterior; so that when we view, feel, and listen to the chest, we may be able to map out the general outlines of the organs within. This knowledge is to be obtained, not only from the common study of anatomy, but also from the frequent comparison of the interior with the exterior, when bodies are opened in the dead-room of hospitals, and from the habit of physical examination itself.

## SECTION I.—EXAMINATION BY SIGHT AND BY TOUCH.

*Mode of Examination.*—The patient being in a standing, sitting, or lying posture, with his arms, legs, and trunk symmetrically placed, and the chest, if possible, entirely uncovered and exposed to a good light, we view it in front, behind, and from above;—carefully marking its form and proportions, and the corresponding prominences and depressions of the two sides. The chest may be viewed from *above*, when the patient is seated on a low seat, with the head a little inclined forward;—the observer standing behind or beside him, and looking down on his shoulders. A view is thus obtained of the depth of the chest from front to back; and in this way may often be detected between the two sides a want of correspondence, that is not perceptible by the ordinary modes of inspection. If the patient's strength do not permit him to stand or sit, the chest may be inspected when he lies on his back, by the observer standing at the foot or at the head of the bed; from which points the corresponding parts of the two sides can be best seen.

*Symmetry of the Chest.*—Most healthy chests are nearly symmetrical, the two sides corresponding in shape and size. There is, however, in almost all instances, a slight superiority in the measured dimensions of the right side; and this is not unfrequently perceptible to the eye, in the lower part of the chest, especially in the back. I<sup>a</sup> have also remarked, in a great many healthy chests, that the left side of the chest, at the upper ribs in front, is somewhat higher than the right. But in spite of the occasional and even frequent occurrence of these anomalous formations, there is sufficient general regularity in the shape and motions of the chest, to render the changes caused by disease available as signs.

*Indications afforded by Sight and Touch.*—By inspection we judge, not only of the statical condition of the chest, but also of its motions. Feeling by the hands will assist the sight; and when we inspect the chest, desiring the patient to breathe in various degrees, with our hands and eyes fixed on corresponding points of the two sides, we watch and feel the amount and equality of the motions. If the chest is healthy, the motions are as uniform as the chest is symmetrical. At each inspiration, the clavicles, scapulæ, and upper ribs rise: the lower ribs rise and spread; and the abdomen swells, as the diaphragm descends. By attentively watching and feeling the chest, we may often likewise so trace the limits of some of the movements, as to indicate the boundaries of the chest. The intercostal spaces and the hollows above the clavicles, are also fit marks for comparison between the two sides. They are strongly marked during full inspiration; and are *more* than usually so, when the entry of air into the lungs is rendered difficult by obstruction of the *tubes*; and *less* than usually so, when the obstruction is more in the *tissue* of the lung, from internal effusion, or external pressure.

There are some general varieties of disordered respiration, which may be distinguished by watching and feeling the motions of the chest. Healthy or perfect respiration is diaphragmatic and costal; but disease may limit the motions to the ribs or to the diaphragm. Thus, when the diaphragm is prevented from descending,—by acute pain in it or below it, or by pressure from below,—the respiration

<sup>a</sup> Dr. C. J. B. Williams.

is wholly performed by the raising of the ribs; and is called "heaving," "thoracic," or "costal." When, on the other hand, the ribs are immovable,—in consequence of pain, ossification of the cartilages and ligaments, or paralysis of the intercostal muscles,—the breathing is wholly "diaphragmatic" or "abdominal." When one side of the chest moves much less than the other, or when a part of one side moves imperfectly, the respiration is "partial;" and this partiality of movement may have its cause in the walls of the chest, or (as is more usual) it may proceed from impermeability of the corresponding portions of the lung, in consequence of various diseases.

*Mensuration of the Chest.*—Mensuration of the chest is a more exact method of detecting inequalities between the two sides. It is generally practised by fixing (with the finger) the end of a piece of tape, or string, at the mesial line of the sternum; and passing the tape horizontally round the chest, to meet at the same spot; when, by taking it off at the point where it crosses the spinous process of the dorsal vertebra, the measure of the two sides may be at once compared. Great care must be taken to pass the tape horizontally around corresponding parts; and attention should also be paid to the degrees of the respiratory act. The most accurate mode is, to compare the measurements of the two sides on a full inspiration and expiration, as well as in the intermediate state; or, without the troublesome process of removing and measuring the tape, it may be sufficient to remark how it is tightened and slackened on the two sides by the motions of respiration. These expedients, together with the practice of inspection downwards on the shoulders, for the antero-posterior diameter of the two sides, are generally sufficient to furnish the comparative dimensions of the sides of the chest.

*Mensuration of its Internal Capacity.*—Besides external measurement, which is essentially *comparative between the two sides*, there have been various attempts to measure the internal capacity of the chest, by noting the quantity of air that can be exhaled or inhaled at a breath, into or from a glass jar over water. The great objection to these as means of diagnosis is, that they depend on the strength of the patient, as much as on the capacity of the chest; and a weak nervous person, with sound lungs, thus tested, would rank lower than a pleuritic or phthisical patient, whose muscular energies are still considerable.

So much for the modes of examining the chest by sight, touch, and measurement. They may often discover to us extensive disease, but they will not inform us of its nature; and they cannot detect the slighter degrees and forms of disease. The chest may be motionless, distended, or contracted, in parts; but whether from diseased lung, obstructed air-tubes, liquid or air in the pleura, or other cause, sight and touch will rarely inform us.<sup>a]</sup>

## SECTION II.—PERCUSSION.

*History.*—[The chest of a healthy person, when slightly struck, ought to yield over its whole extent, more particularly in its anterior and lateral parts, a clear and distinct sound;—owing to the presence of the air, which constantly fills the lungs, and consequently a great portion of the cavity of the thorax. This fact was, no doubt, known to the ancients; and, even in our own times, there are few persons who have not seen the common people striking their chests, and congratulating themselves on possessing what they call "a good *hollow* or *bass*." From the knowledge of this fact, to the conclusion that the same sound cannot exist in cases where the lung is obstructed, or the cavity of the pleura filled with fluid, seems but a step; and yet this reflection appears never to have been made, until made by Avenbrugger, about the middle of last century. After seven years' silent investigation, and (as he himself tells us) amid laborious and disgusting researches,<sup>b</sup>

\* Pathology and Diagnosis of Diseases of the Chest. By Charles J. B. Williams, M. D." Fourth Edition; Pages 1 to 9.

<sup>b</sup> "Inter labores et tædia."

he gave his discovery to the world, in a small pamphlet. The only reward he seems to have obtained for his fine discovery, was a slight notice of it by Van Swieten and Stoll: this, however, failed to attract the attention of his contemporaries; and he died, without ever perhaps dreaming of the celebrity, which his discovery was destined to obtain. Corvisart is entitled to the honour of withdrawing this method from the oblivion into which it had fallen, after a period of thirty years; and of making all Europe, and even the native country of its author, acquainted with its merits.<sup>a</sup>

*Mode of Percussion.*—The patient ought, if practicable, to be either seated or standing; if in bed, the mattress, still more the pillows, and also thick curtains, always render the sound less. The chest ought to be covered with a thin dress; or the physician should have a glove on. This precaution, originally recommended by Auenbrugger, is particularly necessary; inasmuch as the contact of the naked hand and skin occasions a sort of clatter, which renders the pectoral sound less perfect and distinct.<sup>b</sup> It is better that the chest should be covered, and the hand naked; since the glove necessarily diminishes the sensibility of the touch; and because the sensation of elasticity perceived by the operator, frequently confirms his judgment, in cases where the difference of sound is only doubtful. In every case the perception of the sense of fulness or emptiness, conveyed by percussion, is much stronger to the operator than to the mere bystander. Percussion ought to be made with the four fingers united in one line;—the thumb being placed, in opposition to them, at the junction of the second and third phalanges of the index; and used merely in maintaining the fingers in close and strong apposition. We must strike with the *ends*, and not the *face* or *pulpy portion* of the fingers; not obliquely, but perpendicularly; gently, and quickly;—that is, raising the hand immediately from the skin.

When we percuss comparatively the two sides of the chest, we must be careful not to strike successively on parts that are similar, with a like force, and under an equal angle. The omission of these precautions frequently leads to errors of consequence. We ought, in general, to apply percussion to the bones, and not to the intercostal spaces; and to strike the anterior and lateral parts of the chest, in a direction parallel to the ribs. If, however, the intercostal spaces are not very sensible,—as frequently happens in fat or phlegmatic persons,—it is better to strike across the ribs. In any point where the muscles covering the ribs are thick, flabby, or relaxed, we should endeavour to procure their tension. If the muscles are very

<sup>a</sup> Leopold Auenbrug, or Auanbrugger, was born at Graets in Styria, in 1722. He graduated at Vienna; and afterwards became physician in ordinary to the *Spanish Nation*, in the imperial hospital in that city. In Ersch and Puchhelt's "Literatur der Medicin," besides the treatise on percussion, he is recorded as the author of two works on subjects relating to *madness*; and in the "Biographie Médicale" he is farther said to be the author of a *Drama*, and to have published on *Dysentery*. The work on Percussion was first published in 1761, under the title of "Inventum Novum ex Percussione Thoracis Humani, ut Signo, Abstrusos Interni Pectoris Morbos Detegendi" ("A New Discovery, for Detecting the Internal Diseases of the Chest, by Percussing the Thorax"); and the author is said to have died so late as 1809. For a complete view of the subject of Percussion, as introduced by Auenbrug and improved by Corvisart, I beg to refer to the translation of the treatise, in my work entitled—"Original Cases, illustrating the Use of the Stethoscope and Percussion." (Pages 3 to 64.) —*Dr. Forbes.*

<sup>b</sup> This injunction of having the chest covered, so strongly insisted on by the original proposer of the practice and by our author, seems to me of inferior consequence, as far as the accuracy of diagnosis is concerned. In my own practice, I have often followed the interdicted method; and without any inconvenience, as far as I am aware. A much greater authority, Corvisart, did the same; and he gives it as his opinion, that percussion may be equally well performed in one way as the other. (See his "Translation of Auenbrugger," Page 20.) He says, however, that it may be well for beginners to attend to the precaution recommended by Auenbrugger. I would further add, that if the operation can be equally well performed over a garment (as, no doubt, it can), there are very obvious reasons for giving this mode the preference. Our author omits to state the additional and very necessary precaution, given by Auenbrugger, of drawing the shirt or other covering, *tight* over the place.—*Dr. Forbes.*

much relaxed, or if there is œdema or a flabby fatness, it is often useful to stretch and compress the integuments with two fingers of the left hand, and to strike between. In the case of children and lean persons, it is found sufficient to percuss with the extremity of one finger.

When we obtain from percussion only a slight difference of sound on the two sides,—leaving the result doubtful,—it is advisable to repeat the operation:—changing our position to the other side of the patient: in this manner we frequently obtain a result entirely different;—the side most sonorous in the former trial, yielding now a sound inferior to the other. This precaution is never to be omitted in doubtful cases; for percussion yields exact results in the hands of those only who bring to its exercise experience, dexterity, and much attention.

*Character of the Sound derived from Percussion.*—This is different in the different parts of the chest: on which account I shall divide its surface into fifteen “regions,” twelve of which are double:—1. *Subclavian*. This includes merely the portion of the chest covered by the clavicle. When struck about the middle or sternal extremity, this bone yields a very clear sound; its humeral extremity, on the contrary, yields a rather dull sound. A knowledge of the natural and morbid sound of the chest in this region is very important; inasmuch as from it is usually derived the first signs of the development of tubercles in the lungs. When the clavicle is more distant from, or closer to, the chest than usual,—in consequence of the more arched or straighter form of this bone,—the sound is less distinct: this is especially the case in the latter condition of the clavicle. 2. *Anterior-superior*. This is bounded by the clavicle above, and the fourth rib (inclusive) below. The sound is here naturally very clear; though somewhat less so than over the sternal end of the clavicle. 3. *Mammary*. This begins below the fourth rib, and terminates with the eighth. It can rarely be percussed in females; and in the male it seldom yields so good a sound as the anterior-superior region;—on account of the thickness of the inferior edge of the “pectoralis major.” 4. *Submammary*. This extends from the eighth rib to the cartilaginous border of the false ribs. On the right side, it almost always yields a dull sound;—on account of the size of the liver: while, on the left side, it frequently yields a sound clearer than natural, and which may be called almost tympanitic;—owing to the presence of the stomach distended with gas. In very rare instances, the unusual size of the spleen may occasion the dull sound.<sup>a</sup> 5. *Sternal—Superior, Middle, and Inferior*. Over the whole extent of the sternum, the sound is as clear as on the sternal end of the clavicle. In certain cases, however, particularly in very fat persons, the lower portion of the sternum yields a duller sound;—on account of the great quantity of fat about the heart.<sup>b</sup> 6. *Axillary*. This extends from the upper part of the axilla, to the fourth rib (inclusive): it yields naturally a clear sound. 7. *Lateral*. This is bounded superiorly by the fourth rib, and terminates with the eighth. The sound in this region is always good on the left side; on the right, it is frequently much less;—owing to the liver rising higher than usual; and thereby compressing the lung upwards, and rendering it more dense and less charged with air. The liver, when sound, never extends above the level of the sixth or fifth rib. 8. *Inferior Lateral*. This is bounded above by the eighth rib, and terminates with the border of the false ribs. For the reasons just mentioned, this region on the right side yields a completely dull sound, and is almost always much less sonorous than the left. This last, on the contrary,—for reasons already stated,—frequently yields a clearer sound than natural; and this even when the inferior portion of the lung is

<sup>a</sup> Andral is of opinion that the dulness of this region on the left, owing to the presence of the spleen, is of more frequent occurrence than is commonly imagined.—(Tome 2; Page 338.)—*Dr. Forbes*.

<sup>b</sup> Avenbrugger considers this diminution of sound, under a part of the sternum, as general. He says that “the whole sternum, on percussion, sounds as clearly as the sides of the thorax; except at that part behind which lies a portion of the heart; for there the sound is a little duller.” The opinion of Corvisart coincides with that of our author. I have myself frequently found the sound dull in this point, when there was no reason to suspect disease of the heart.—*Dr. Forbes*.

obstructed, or there exists an effusion of fluid in the pleura. 9. *Acromion*. This is comprehended between the clavicle, the upper edge of the "trapezius" muscle, the head of the humerus, and the lower part of the neck. Here there is no sound whatever;—the soft parts in this place yielding passively to the percussion. 10. *Upper Scapular*. This corresponds to the supra-spinal fossa of the scapula, and hardly yields any sound;—on account of the muscle that fills it. The spine of the scapula, which bounds this region below, sometimes yields a slight sound, but never considerable; and this only when the arms are very forcibly crossed. 11. *Lower Scapular*. This corresponds to the portion of the scapula below its spine; and, on account of its muscles, yields no sound. 12. *Inter-scapular*. This includes the space between the inner margin of the scapula and the spine, when the arms are crossed on the breast. It is not easy to elicit any sound from it; on account of its muscles. Sometimes, however, it yields a middling but sufficiently distinct sound; especially in thin persons; and when the arms are strongly crossed, and the head bent;—so that the "rhomboid" and "trapezius" muscles are made quite tense. The spine in this region gives a good sound; as does also that portion of the chest included between the inner and upper angle of the scapula, and the first dorsal vertebra. 13. *Inferior Dorsal*. This begins at the level of the lower angle of the scapula, and terminates at the twelfth dorsal vertebra. To elicit from this region all the sound it is capable of yielding, we ought, especially in fat subjects, to endeavour to find the angle of the ribs, and to percuss on that point in a transverse direction. In the upper part of the region, the sound is pretty good; a little lower, it is often slight or none; and on the right side, it is almost always obscure;—on account of the presence of the liver. On the left side, it frequently yields the factitious sound so often mentioned as owing to the presence of the stomach.

Percussion of the chest has great advantages; because it enables us to detect the existence of an obstruction of the lungs, or an effusion into the pleura, of moderate extent; but it cannot discriminate these from each other. Many causes, moreover, conspire to circumscribe the number of cases in which it is of use. We have just seen, that in many places of the chest it gives no satisfactory result; and its chief indication (that of *fulness*) is not obtained, in pulmonary diseases, until the organic change is already far advanced. Its indications are very equivocal when the disease occupies the centre, or roots of the lungs, or when both lungs are simultaneously affected; they are deceptive when the chest is deformed, even in a slight degree; and they are extremely uncertain, or cease entirely, when the integuments are œdematous or loaded with fat; or when they become flabby, from the removal of this excessive degree of obesity.\*]

*Mediate Percussion*.—[As the walls of the chest give the sound which we hear on striking the chest, so it is plain that they must be sufficiently tense and elastic to vibrate on being struck. The chests of some persons are so loosely put together, and so flaccid, that they give but little sound; although the organs within are quite healthy. In others, again, there is such a mass of fat and loose integument on the chest, that the walls are completely muffled by it, and they sound but little on percussion. The same difficulty occurs in other cases, in certain regions where muscles of considerable thickness, or the mammae in females, lie on the walls. In other instances, again, the walls of the chest are so drawn in by contracted adhesions of the pleura, that they are too tight to vibrate, and give a hard or dull sound; although the lungs within them may be comparatively healthy. In all these cases, we must give to the part struck the equal tension which is wanting, by pressing on it a small piece of some firmly elastic body; such as wood, ivory, whalebone, stiff india-rubber, or some such substance. This, when struck, gives sound enough; and if it be firmly applied to the chest, the density of the contents within will modify this sound;—just as it modifies that of percussing on the naked walls of the chest. The sound obtained by striking a little plate of ivory or wood thus

\* "A Treatise on the Diseases of the Chest; by R. T. H. Laennec, M. D. Translated by John Forbes, M.D." Third Edition. Pages 15 to 22.

pressed on the chest, is the same in character as that of striking the chest itself; but it is louder; and as percussion on it gives no pain, the stroke can be applied with such force, as to make the vibrations reach the interior through any thickness of fat or muscle. By these means, we can test the sonorous qualities of the thoracic viscera, through the scapulæ and muscles of the back; and through fat or œdematous integuments, of any thickness. In this way, too, we can try the resonance or sonorous quality of any part of the abdomen.

We owe this method of *mediate* percussion to M. Piorry; who calls this percussion-plate "a pleximeter." Mediate percussion is so much better than the immediate kind, that it is now generally preferred. There is, however, an improvement on it, which was (I believe) first proposed by Dr. Skerrett; it is to substitute for a pleximeter the fingers of the left hand. This mode of percussion has the advantage of convenience, as well as of yielding distinct results. Its adaptations are soon found out by a little experience;—in fitting the fingers to the inequalities of the chest, sometimes single, sometimes together, sometimes with their palmer surface outwards; but generally with this surface applied to the chest, and the back to strike on;—with other varieties of manipulation.\*]

### SECTION III.—AUSCULTATION.

For the purpose of listening to the chest, in order to hear these sounds, some employ the naked ear; but it appears to me that it would be better to employ the intervention of a foreign substance,—a piece of wood. I think if we only employ the ear, we cannot examine every part of the chest so frequently as may be desirable; and it is not so convenient. If the patient be a young lady, and the physician a young gentleman, perhaps mamma will not be pleased at his laying his ear on her daughter's bosom; and if the patient be a greasy old fellow in the hospital, we shall not like it. Upon the whole, therefore, I think it much better to employ a piece of wood. I do not think that persons who use the ear only, do so well as others. I have known such persons give extraordinary opinions; and a great many of them are not capable of saying which instrument is the best.

*The Stethoscope.*—[We want an instrument, then, to transfer the sounds from the chest to our ear. This instrument must be a good conductor of sounds; and as the power of bodies to conduct sounds depends on the strength and uniformity of their elasticity, and their capacity to vibrate like the body that produces the sound, we must have an elastic material, of density resembling that of sources of sound within the chest, and of the walls of the chest through which they are transmitted. But the sources of the pectoral sounds vary. Some, as the voice and respiration (or at least the hollower sounds of respiration), are produced in air; while, in others,—such as the sonorous rhonchus, the rubbing sound, and the sounds of the heart,—the solids are chiefly concerned. We shall, therefore, need a varied capacity in our instrument, to receive these sounds.

To transmit the sounds originating in the solids within the chest, we must have a uniform solid; and the lighter it is the better, provided it be thoroughly rigid. Nothing answers to this description so well as wood; and in the light kinds of wood, with a stiff, longitudinal fibre,—such as pine wood, deal, cedar, and the like,—we find these qualities in perfection. Through a cylinder of such wood,—about eight inches long, and an inch and a half in diameter, adapted to the ear at one end,—most of the pectoral sounds may be heard, but those best which originate in solids; such as the sounds of the heart, of friction, and sonorous rhonchi. The sounds of respiration and of the voice are also heard through it; but not nearly so distinctly as with the naked ear.

We need, therefore, an aerial conductor for these sounds; because they originate in air, and can best be transferred through air. By perforating the cylinder with

\* Dr. Williams, on "Diseases of the Chest;" Pages 14 and 15.

a bore, a quarter of an inch in diameter, it becomes a tube; through the columns of air in which, the respiration and voice may be heard with increased distinctness. But as this column of air is in contact with only a small spot of the chest, it can transmit only the sounds produced under or very near that spot; and the instrument thus prepared is better adapted to explore small parts of the chest, than the ear can be. But we want the instrument also to transfer the sounds of larger spaces. The sounds of so limited a space, are often too weak to be heard alone; and, besides, it would be very tedious to go over the whole chest, *dotting* in this way a quarter of an inch at a time. Now, if the column of air be enlarged at the base, where it is in contact with the chest, by hollowing out the wooden cylinder into a funnel-shape, it will conduct the sounds produced on this greater extent of surface; for they are reflected by the funnel into this central bore, and conveyed concentrated to the ear. This also gives the instrument the power of concentrating or magnifying the sounds; which are thus heard as strong at the distance of several inches, or even a foot or two from the chest, as they are to the ear in close contact with it; nay, in some cases they are even stronger. The best shape for the excavated end, is that of a long funnel or cone, with its apex terminating in the central bore; for this directs the sound at once to the ear, without repeated reflections, which may modify it. As we still sometimes want to explore small spots of the chest, by means of a perforated plug the excavated end can be filled, and the instrument reconverted into a simply perforated cylinder. To make the instrument more portable, the upper part of the cylinder may be reduced to a stem half an inch or less in diameter, leaving only at the top a sufficient width for the ear; or this top may be made of a harder wood. Wood is so excellent a conductor of sound, that when once the vibrations are in it, they can be conveyed by a very small body of fibres.

*Uses of the Stethoscope.*—Thus the stethoscope, although a simple instrument, performs several offices in relation to sound; the chief of which may be enumerated as follows:—1. To conduct sound by its solid walls. 2. To conduct and concentrate sound by its closed column of air. 3. To transfer sounds from its column of air to its solid walls, or the converse, when circumstances impede their transmission by one of these ways. 4. To diminish this power of transfer, and contract the field of hearing when small spots are to be explored.<sup>a]</sup>

*Mode of Using the Stethoscope.*—[The general precautions which the practice of auscultation requires, are the following:—1. The stethoscope must be applied very exactly and perpendicularly to the surface on which it rests; so as to leave no interval between the skin, and any part of the extremity applied. 2. We must be careful not to produce pain by too strong pressure: this precaution is most necessary when the instrument is used without the stopper, and when the person is lean. 3. Although it is not necessary that the chest should be uncovered,—as all the positive stethoscopic signs, and frequently also the negative ones, may be perceived through clothes of considerable thickness, provided they are applied closely to the body,—still it is better that the clothing should only be light;—for example, a flannel waistcoat and shirt. Silks, and also woollen stuffs, are often inadmissible, on account of the noise occasioned by their friction against the instrument. The examiner ought to be careful, above all things, not to place himself in an uncomfortable posture, or to stoop too much, or turn his head backwards by a forced extension of the neck. These positions determine the blood to the head, and thus obscure the sense of hearing: they may sometimes be properly avoided by kneeling on one knee. In examining the fore parts of the chest, we ought to place the patient on his back, in a recumbent position; or in a chair, and gently reclining backwards. When we examine the back, we cause the patient to lean forwards, and to keep his arms forcibly crossed in front; and when we examine the side, we cause him to lean gently to the opposite one, and to place the forearm on the head.<sup>b]</sup>

<sup>b</sup> Laennec on the Chest; translated by Forbes. Third Edition; Pages 27 and 28.

### a. Auscultation of the Respiration.

**Respiratory Murmur.**—The penetration of the air into the organs of respiration, is accompanied by a slight murmur, which is distinctly perceived by the aid of mediate auscultation, and is called “the respiratory murmur.” This sound of the passage of the air in the pulmonary tissue, the larynx, the trachea, and the great bronchial branches, presents a different character in each locality. *In the first case*, the sound is somewhat soft and silky; and the ear recognizes the penetration of the air into a multitude of little cells, which are dilated to receive it: this is the true pulmonic respiratory murmur, which is also called “vesicular respiration.” *In the other cases*, the sound is more rough, and is deprived of that crepitation which accompanies the expansion of the air-cells; the passage of air through tubes of various dimensions is thus perceived: this is the bronchial respiratory sound; or, more simply, “bronchial respiration.”

**Pulmonary or Vesicular Respiration.**—In health, the “vesicular respiration” is heard almost equally at all points of the chest; yet it is more plainly heard at those parts where the lungs are nearest to the surface; as at the arm-pits, the space between the clavicle and the “trapezius” muscle, and between the same bone and the mammæ. The “respiratory murmur” is loud in proportion to the rapidity of the respirations: a slow and deep breathing scarcely, but a short breathing (though incomplete) plainly, develops the respiratory murmur. Hence the inspiration is louder than the expiration; which is not performed, in ordinary circumstances, so rapidly as inspiration; and the elasticity of the lungs assists the exit of the air. “Vesicular respiration” is more energetic and blustering in children than in adults; and still more so than in old persons. The younger the infant, the more marked is this energy; and it continues until, and a little beyond, the age of puberty.

The *intensity* of the “respiratory murmur,” differs in different individuals. With some it is heard with difficulty, unless in a strong respiration; with some it is heard with facility, even though the breathing be gentle; while others retain, during their whole life, the energetic murmur of infantile vesicular respiration; and it is then called “*puerile* respiration.” This last species of breathing sound (the “*puerile*”) is, for the most part, heard in females and men of a very nervous constitution; and, with the exception of these two classes, respiration never becomes puerile in the adult, except when a considerable portion of the lungs becomes, from some cause or other, impermeable to the air. When “vesicular respiration” is heard with equal force in all points of the chest, the lungs are in a healthy state; when, on the contrary, this respiratory murmur is diminished or annihilated at any part of the thoracic surface, we may conclude that the corresponding part of the lungs has become impermeable to the air, in a greater or lesser degree.

**Bronchial Respiration.**—“Bronchial respiration,” in a state of health, is only heard on the anterior and lateral parts of the neck. But in some very thin persons, it may be heard towards the upper extremity of the sternum, and in the interscapular space. In all other parts, the respiratory sound in the small bronchial branches, is confounded with the “*vesicular* respiration.” When, from any cause, the pulmonary tissue becomes hardened or condensed, the “bronchial respiration” replaces the “*vesicular*,” and thus it becomes one of the first signs of hepatization of the lungs, of the accumulation of tubercles in this organ, of an effusion, &c. “Bronchial respiration” becomes a sign of greater importance, in proportion to the distance at which it is heard from the interscapular spaces; therefore, it is a matter of the highest necessity, to practise the ear in distinguishing “bronchial” from “*vesicular*” respiration.

**Cavernous Respiration.**—[When, from any cause, an excavation is formed in the lungs, the penetration of air into such cavity produces a sound similar to “bronchial respiration,” when heard at the anterior part of the neck: this is “*cavernous* respiration.” “Cavernous” and “bronchial” respiration are sometimes so modified, that in inspiration the air seems as if drawn *from* the ear, and

in expiration as if driven back into the ear, of the auscultator: this is the “*blowing respiration*,”—a decidedly morbid phenomenon; demonstrating the near approach of the excavation, or of the bronchia which pass into it, to the surface of the lungs. This “*blowing respiration*” sometimes resembles the agitation of a movable veil (or sail), placed between the ear of the auscultator and the pulmonary excavation. This veiled blowing appears to arise from an unequal density of the sides of the excavation in which it takes place.”]

*Modified Breath-sounds: Rhonchi.*—[We<sup>b</sup> have now to describe a class of novel sounds, which arise from *partial obstructions* to the passage of the air;—obstructions which permit the air to pass, but not without such a resistance as causes an increased and modified sound. Thus, if a bronchial tube be narrowed by the swelling of its membrane, or by mucus secreted by it, the air will pass through the narrowed portion with increased velocity and increased resistance; and hence the sound is changed from a simple breathing or blowing, to a louder wheezing, bubbling, whistling, or snoring,—according to the nature of the obstruction. These new sounds Laennec called *râles*, or *rattles*. If we must use a separate word, I<sup>a</sup> should prefer the Latin term *rhonchus*, (which is from the Greek *ῥογχος*,) as more expressive, and it has been adopted by many English writers. If there were one, it would be desirable to use an English word; for nothing injures the purity of a language more than the introduction of foreign words. The rhonchi may be produced in inspiration, in expiration, or in both. They may be divided into the “dry” and the “humid;”—according as the impediment that produces them is solid or liquid.

*Dry Rhonchi.*—1. *Sibilant.*—Of the “dry” rhonchi, there is the “sibilant,” or “whistling” rhonchus; which is sufficiently described by its name, and may generally be imitated by whistling between the teeth. It is produced by the passage of air through a small and somewhat circular aperture; and this aperture may be formed by a slight obstruction of a small tube, or by a greater obstruction in tubes of larger size. It generally occurs in tubes narrowed by swelling of their mucous and submucous coats;—such as occurs in the early stage of acute bronchitis; but it is heard also in asthma, where the tubes are congested and constricted by the spasmodic contraction of their circular fibres; and it may happen, also, when viscid mucus clings to and diminishes the calibre of the tubes.

2. *Sonorous.*—The “sonorous” rhonchus is a snoring, humming, or droning sound; and may vary in loudness or key from an acute note, like the hum of a gnat, down to the grave tone of a violoncello or bassoon. It must be produced by an obstruction leaving a flattened aperture; the lips of which, or the moisture on them, yield to the passing air with a vibrating resistance. Partial swelling of the sides of a tube, particularly at its bifurcation, a pellet of tough mucus in it, or external pressure on it, may cause such a flattened opening within the tube; and the sound in question, therefore, occurs in various forms of bronchitis, and often accompanies tumours, which press on the bronchial tubes. When caused by tough phlegm, coughing generally changes or removes it; when from the other causes, it is generally more permanent. When quite permanent, it usually depends on the pressure of a tumour, or some deposit outside the tube.

3. *Dry Mucous.*—There is another rhonchus, which may be called the “dry mucous;” because it is produced by a pellet of tough mucus obstructing the tube, and yielding to the air only in successive jerks; which cause a ticking sound, like that of a click-wheel. When the air is driven very fast, these click-sounds pass into a continuous note, and constitute the “sonorous” rhonchus. Sometimes, again, particularly in inspiration, the click-sound suddenly stops;—the tough mucus being forced into a smaller tube, which it completely closes, and may not be dislodged again but by dint of forcible coughing.

*Humid Rhonchi.*—The “humid” rhonchi depend on the passage of air, in

\* “A Manual of Auscultation and Percussion; compiled from Laennec’s Great Work.” By James B. Sharpe. Second Edition. Page 16.

<sup>b</sup> Dr. C. J. B. Williams.

bubbles, through a liquid in the lungs; and their varieties are produced by differences in the size of the tubes, and in the nature and quantity of the liquid; which cause differences in the bubbling sound.

1. *Mucous*.—The “mucous” rhonchus may be heard in large and smaller bronchi, down to the size of a crow’s quill; and, in these tubes, its gurgling or crackling presents different degrees of coarseness. It is an irregular and varying sound; composed of unequal bubbles, and often interspersed with some whistling, chirping, or hissing notes. Its most common cause is acute bronchitis; which, after its onset, is attended with a secretion of liquid mucus into the bronchial tubes; and the passing of the “sibilant” and “sonorous” rhonchi of the first or dry stage, into the “bubbling” of the second or secreting stage, is often marked by a curious combination of chirping and cooing notes, like those of birds in a bush.

2. *Cavernous*.—When the bronchial tubes become enlarged by disease, or when morbid cavities are formed by the destruction of portions of the lung, the bubbling of air through liquid in these is of the coarsest kind. It is quite gurgling; and if the liquid be scanty, has a hollow character, and is called “cavernous” rhonchus.

3. *Submucous*.—When there is a little liquid in the smaller bronchi, the bubbling or crackling is more regular; although the sound is weak, and is sometimes only a roughness added to the ordinary respiratory murmur. This is the “submucous” rhonchus. It may result from slight degrees of bronchitis; and owes its importance only to its being permanently present, when such slight inflammation is constantly kept up by the irritation of adjacent tubercles in an incipient state.

4. *Subcrepitant*.—When there is more liquid, not viscid, in the smallest tubes and terminal cells, the rhonchus has a still more crepitating character; and resembles that heard on applying the ear near the surface of a liquid slightly effervescing;—such as champagne, or bottled cider. This is the “subcrepitant” rhonchus; which is heard in œdema of the lungs, humid bronchitis, and other affections, in which liquid and air occupy the extreme tubes, and are forced through each other in the motions of breathing.

5. *Crepitant*.—But the most perfect and equal crackling, is that of peripneumony: it is therefore called the “crepitant” (“crackling”) rhonchus. It exactly resembles the sound produced by rubbing slowly and firmly, between the finger and thumb, a lock of one’s hair near the ear. I believe this sound to depend on the forcible passage of air through a little viscid mucus in the finest tubes, narrowed by congestion and deposit around them.

All these different rhonchi may occupy the whole of the respiratory movements, or be confined to part of them. Thus, an obstruction which is sufficient at the commencement of inspiration to cause a rhonchus, may be insufficient when the tubes are dilated by the distension of a full breath; or there may be the converse;—an obstruction which is total in low degrees of respiration, and stops all sound, occasions a rhonchus in forced or extensive efforts; as in coughing. This suggests to us the propriety of using these different degrees of respiration, to test the nature and extent of bronchial obstructions. It may also be inferred, from what has been said, that the different stages and degrees of force in respiration may change the note of the different rhonchi; and thus produce such a variety, as that which we hear in the chests of some catarrhal and asthmatic patients. Laennec used to call this combination of piping sounds—“rhonchus *canorus*.” It may be readily conceived, too, that these several rhonchi may be variously combined; or exist at the same time in different parts of the lungs; and give rise to numerous combinations, on which it is useless to dwell. The loudness of a “sonorous” or “sibilant” rhonchus, is no proof of the severity of the disease; nor is the fact of its being audible over the whole chest, unless the natural breath-sound be, at the same time, absent or very feeble in parts. But the presence of the “bubbling” rhonchi, does imply mischief proportioned to its extent; and if they are heard over a large space, and accompany the whole act of respiration,—diminishing or superseding the natu-

ral breath-sound,—they denote disease of a very serious character; because, as our hearing informs us, there is an obstructing liquid in the tubes where there ought to be only air, and the function of respiration must be injured in proportion.<sup>a</sup>]

### *b. Auscultation of the Voice.*

*Natural Voice Sounds.*—When any one, in a healthy state, speaks or sings, the voice resounds through every part of the respiratory organs. If we seek by auscultation to discover the nature of this resonance, we shall find it to differ in the larynx, the trachea, the bronchia, and the pulmonary tissue. The voice resounds so forcibly in the larynx and the superior portion of the trachea, that when heard through the medium of the stethoscope applied over those parts, the other unassisted ear does not distinguish the sound of the voice proceeding from the speaker's lips. This resonance is not so loud at the inferior portion of the trachea; and is still less so when the stethoscope is applied to the upper portion of the sternum. This resonance is yet strong, though diffuse, in the great bronchial branches situated at the root of the lungs, and which we explore by applying the stethoscope to the interscapular spaces. The sound of the voice does not pass through the instrument, but sounds at its extremity: nevertheless, the resonance is heard more plainly than the voice itself. In the pulmonary tissue, and in the expanded bronchial ramifications, this resonance is scarcely heard; and the stethoscope discovers nothing more than a slight trembling;—such as may be felt by the hand placed upon the chest of the speaker. But, in those who have a powerful and deep voice, this resonance is at all times to be heard, upon whatever point of the thoracic surface the stethoscope be applied, as powerfully as at the interscapular spaces of ordinary persons.

*Bronchophony.*—[If from any cause the lungs become impermeable, the resonance of the voice becomes audible in the small bronchial branches; and it increases greatly in the larger branches, if the induration is in a part situated near the root of the lungs: such resonance is called “bronchophony.” This effect also takes place when the small bronchial ramifications are dilated; so much so, that the resonance is heard almost as plainly as at the larynx. “*Accidental bronchophony*,” therefore, indicates either an induration of the pulmonary tissue, or a dilatation of the small bronchia, or both combined at the same time. “*Bronchophony*” may be heard at all points of the thoracic surface. But it is more frequently recognized at the interscapular spaces, and the subspinal fossæ of the scapulæ;—on account of the proximity of the great bronchial branches, and the frequency of the hepatization of the inferior lobes of the lungs. It also as often occurs at the arm-pits, and beneath the clavicles;—by reason of tuberculous indurations which are so very frequently developed at the summit of the lungs.

*Pectoriloquy.*—When there is an excavation of the lungs, communicating with the bronchia, the resonance of the voice is heard over the place, just as upon the larynx. This is called “*pectoriloquy*,” which is either “perfect,” “imperfect,” or “doubtful.” It is “perfect,” when the voice appears to issue directly from the chest, and to pass entirely through the tube of the stethoscope. It is “imperfect,” when the transmission of the voice is not complete, notwithstanding the presence of every other local symptom of excavated lungs. It is “doubtful,” when the resonance is very feeble, and only to be distinguished from bronchophony by signs drawn from the place where it is heard, and from the history of the disease. “Perfect pectoriloquy” is the result of the complete vacuity of the excavation; the greater density of the pulmonary tissue surrounding the excavation; the communication of somewhat voluminous bronchia with the cavity, and the proximity of the cavity to the parietes of the chest. It is generally the sign of an excavation of middling size. It is also very evident in small cavities;—provided they are surrounded by hardened lung, and are near the surface of the lungs; but

<sup>a</sup> Dr. C. J. B. Williams, on “Diseases of the Chest,” Pages 27 to 31.

in very large excavations, wherever their seat, pectoriloquy is almost always very slight. "Pectoriloquy" is suspended occasionally, during a greater or lesser time, if the bronchia which communicate with the excavation are obstructed by expectoration. It is diminished, or ceases entirely, when the cavity communicates with a vast number of bronchia, or opens into the pleura. It may take place at any point of the thoracic surface; since excavations may be formed in any part of the lungs; but as excavation is generally the consequence of a resolution of tubercles, and as these tubercles are principally developed in the upper portions of the lungs, it follows that pectoriloquy is most frequently heard beneath the clavicles, and in the hollow of the arm-pits. Dr. Elliotson states, that pectoriloquy may often be easily detected, on making the patient speak in a strong whisper, although it be doubtful when he speaks aloud. He also recommends that, when there is any doubt as to pectoriloquy or bronchophony, the voice should be explored on each side, for comparison, with the plug of the stethoscope removed.\*]

*Ægophony*.—"Ægophony" is a particular resonance of the voice, which is heard at nearly the same points as "bronchophony," and is often coincident with it; but it is the result of very different anatomical conditions. "*Simple ægophony*" is characterized by a tremulous jerking voice, like that of the goat; with an acute silvery tone, not possessed by the natural voice of the patient, rarely heard as if within the stethoscope, and seldom if ever passing through it. In one case ægophony is pectoriloquous,—passes distinctly through the tube, like pectoriloquy; and this is where the portion of lung, which has an effusion around it, (producing the ægophony,) is solidified. When it is heard with "bronchophony," this goat-like voice resembles that of a man speaking with a counter between his teeth and lips; or still more that of *Punch*. The existence of effusion into the pleura, is the anatomical condition producing ægophony. But this effusion must not be very abundant. For, if so, ægophony is no longer heard; it is again manifest when the effusion diminishes, and finally disappears with the fluid by degrees. It therefore coexists with pleurisy, and continues from the first to the third day: it exists only for a few days in *acute* pleurisy, but continues many months when this disease is *chronic*. In both cases it is a favourable symptom; since it proves the effusion to be of small extent. "Ægophony" may not be present in pleurisy under three conditions:—1. When the effusion of fluid is very rapid and very abundant. 2. When old adhesions obstruct the effusion of fluid into the pleura. 3. When there are false membranes without effusion. Those who have thought that "ægophony" was audible in this last case, have mistaken it for "bronchophony." When the patient stands or sits, "ægophony" is heard between the spinal column and the scapula, and along a zone of three fingers' breadth, drawn from the inferior angle of the scapula to the nipple, following the direction of the ribs. When he lies in a prone position, it is heard only at the side. The extent over which "ægophony" is heard, will hardly allow it to be confounded with "pectoriloquy." The latter is bounded by narrow limits; is rarely discoverable at the same place with "ægophony;" has not the jerking character; and is moreover accompanied by "cavernous respiration," and other signs of excavation. "Ægophony" is distinguished from "bronchophony," with which it often coexists; inasmuch as the latter is constantly accompanied by "bronchial respiration," and is always heard at the same place,—whatever may be the position of the patient; while "ægophony" changes its place with a change of position, and is generally attended by a pure respiratory murmur, although it be but feeble. The distinction of "ægophony" and of "bronchophony," as the one or the other may exist alone or predominate, determines whether the pleurisy is simple, or complicated with pneumonia; and which affection is the more serious; or whether pneumonia alone exists. To hear distinctly that goat-like voice which forms the principal characteristic of "ægophony," the stethoscope should be firmly applied to the chest, and the ear placed lightly upon its auricular extremity.

\* Sharpe's "Manual of Auscultation;" Pages 18 to 21.

*Metallic Tinkling.*—By “metallic tinkling” is meant that sound which may be perfectly initiated by gently striking a piece of metal, glass, or china, with a pin; or by dropping grains of sand or pins into a glass. “*Metallic tinkling*” is heard when the patient breathes, speaks, or coughs; but more feebly in the former than in the two latter cases; sometimes the reverse of this happens, but that is an extreme case. When pectoriloquy exists at the same time, this metallic tinkling and the voice traverse the tube of the stethoscope; but, when pectoriloquy is not present, a light acute sound is heard within the chest;—analogous to the vibration of a metallic string struck with the finger. “*Metallic tinkling*” can be heard in two cases only:—1. In that of the coexistence of a serous or purulent discharge in the pleura with pneumato-thorax. 2. When a large tubercular excavation is partly filled with liquid pus. “*Metallic tinkling*,” therefore, may be taken as a sign of a triple lesion, when pneumato-thorax is joined to empyema; since there must exist at the same time a fistulous communication between the pleura and the bronchia;—the result of a tuberculous vomica, of an abscess in the lungs, or of a gangrenous eschar. The magnitude of the fistulous opening, and the relative proportions of air and fluid poured out, may be ascertained by this sound; since, the more clearly the tinkling is heard, the greater is the fistulous opening; and the greater the extent of the vibrations, the larger is the space filled with air; but the maximum of sound is (perhaps) when the air and fluid occupy equal spaces. Thus this space may be estimated (with sufficient accuracy) by the stethoscope, and by percussion exercised at the same time at different points; when a resonance similar to that of an empty cask, mixed with the tinkling, will be heard. Sometimes this sound passes into another, similar to that which is produced by blowing into an empty decanter: this is the “bottle-buzzing” or “amphoric” sound. Respiration, the voice, and cough equally display it. There are two circumstances which produce this “buzzing resonance” more frequently than the tinkling; although sometimes these sounds succeed one another, or are alternately produced for uncertain periods, or even heard simultaneously;—1. When two or more fistulous openings exist between the cavity occupied with air and the bronchia. 2. When this cavity is extremely vast, and contains but a small quantity of fluid. “*Metallic tinkling*” may be evinced by a fact quite independent of the voice, cough, or respiration. Thus, when pneumato-thorax with an effusion of fluid has taken place, and the patient is made to sit up, sometimes a drop of the fluid which was retained above falls down at the moment of examination;—producing a sound similar to a drop of water let fall into a decanter three parts empty; and it is accompanied by an evident “metallic tinkling.” The latter, and the “amphoric buzzing,” are always heard after the operation for empyema; as long as there is a communication between the cavity and the air, either by the external wound, or by a fistulous opening.

There is a phenomenon of no value as a sign, but which might be mistaken by the inexperienced for the metallic tinkling:—it is produced by the friction of some hard parts upon one another, where the ribs allow much mobility of parts; and resembles the sounding of fire-arms in military exercises.

### *c. Pleural Friction-Sound.*

[There is a heavy sound similar to that which is produced, under the stethoscope, by rubbing the finger against a bone: this is called “the *ascending and descending* friction sound.” It is the result of interlobular emphysema; and, in conjunction with the “dry crepitant rattle, with great bubbles,” becomes a sign of that disease. This “friction-sound” takes place in the following circumstances:—1. When the internal surface of the pleura becomes unequal or wrinkled. 2. In pleurisy, when there is little or no effusion, and when the pleura is covered only with false membrane, more or less thick. 3. When there is moderate effusion; and old adhesions do not, in certain positions of the body obstruct the lungs; while rising above the level of the fluid, and rubbing against the sides of the chest, at a

point where the ear may be applied. This friction disappears when the effusion is very abundant; and reappears as the fluid diminishes. It is sensible to the hand, as well as to the stethoscope: it may sometimes be heard by a distant observer, and even perceived by the patient himself. The habitual friction between the two glistening surfaces of the pleura, gives out no appreciable sound;—owing to their extreme polish. It takes place only when the healthy surfaces are changed by disease, or other causes.\*]

The subjoined tabular view of the chief phenomena of auscultation of the organs of respiration, is extracted from Dr. C. J. B. Williams's work on the Diseases of the Chest.

### SOUNDS PRODUCED BY THE PASSAGE OF AIR IN RESPIRATION.

#### SOUND OF RESPIRATION, OR BREATH-SOUND.

*Natural; produced by collision of the air against the sides and angles of the air-tubes.*

*Tracheal; heard in the neck and at the top of the sternum.*

*Bronchial; near the upper parts of the sternum, between the capsulæ, &c.*

*Vesicular; in most other parts of the chest.*

Morbid, modified in production or transmission.

Bronchial, or whiffling; transmitted from the bronchi by condensed tissue of the lung.

Cavernous } produced in morbid cavities communicating with the bronchi.  
Amphoric }

RHONCHI, produced by increased resistance to the air moving through the lungs.

Dry; Sibilant } produced by viscid mucus in the bronchi, or by swelling of  
Sonorous } the membranes, or by pressure upon them.  
Dry Mucous }

Moist; Mucous . . . } produced by a bubbling } liquid in the bronchi.  
passage of air through }

Submucous . . . . . } liquid in the finer bronchi.

Subcrepitant . . . . . } liquid in the smallest bronchi.

Crepitant . . . . . } viscid liquid in compressed smallest  
bronchi.

Cavernous . . . . . } liquid in a morbid cavity.

### SOUNDS OF THE VOICE TRANSMITTED THROUGH THE CHEST.

#### NATURAL SOUNDS, heard in a healthy chest.

*Tracheophony; in the neck and at the top of the sternum.*

*Bronchophony; near the top of the sternum, between the scapulæ, in the axillæ, &c.*

*Pectoral voice-sound; in many parts of the chest.*

#### MORBID SOUNDS, transmitted or produced by a diseased chest.

Bronchophony, transmitted by condensed pulmonary tissue.

Ægophony, the same vibrating through a thin layer of liquid.

Pectoriloquy, resounding in a cavity in the lung.

Tinkling, a changed echo of the voice or cough in a large cavity.

### SOUNDS PRODUCED BY THE MOTIONS OF THE LUNGS.

Sounds of friction, when the pleuræ are dry, or rough from deposits.

Emphysematous crackling, by the irregular passage of air between the lobules.

## SECTION IV.—GENERAL REMARKS ON THE DIAGNOSIS OF PULMONARY DISEASES.

[Having given a short sketch of the sources of physical diagnosis, I<sup>b</sup> shall announce the great principles that govern their application to the detection of disease. These may be stated as follows:—1. The value of most of the preceding signs, or of their combinations, in the determination of the seat, nature, or extent of disease, is to be estimated more by comparison with the phenomena of other portions of the chest, than by their mere existence in a particular situation. 2. The

<sup>a</sup> Sharpe's "Manual of Auscultation;" Pages 36 and 37.

<sup>b</sup> Dr. Stokes.

greater the number of physical signs which can be combined in any particular case, the more accurate will our conclusions be. But of these combinations, the most important and indispensable is that of the passive and active auscultatory phenomena. 3. The existing physical signs, are to be considered in relation to the period of duration of the disease, and the rapidity or slowness of their own changes. 4. In all cases, the value of physical signs must be tested by the existing symptoms and previous history; while, on the other hand, the observation of these physical signs, enables us to correct the conclusions to which the unaided study of symptoms would lead us.

In the cases we are every day called to treat, the value of physical signs must be tested by the history and symptoms; and these, in their turn, must be corrected by the physical signs. Whoever neglects either source of information, will fall into the most fatal errors. We must have recourse to the assistance of each and every one of these means; and even still, with all this combined knowledge, we shall meet with cases, the real nature of which is involved in the greatest obscurity. Indeed, when we reflect on the infinite complications of disease, modified by circumstances infinitely numerous, it would be strange if such did not arise; and there can be no doubt, that if our means of diagnosis were extended one hundred-fold beyond their present state, the same circumstances would still occur. Physical signs form an addition,—constitute an assistance to diagnosis, but nothing more; yet of their value every impartial mind must be convinced, who compares the state of our knowledge previous and subsequent to their discovery. It is on the discovery, explanation, and connection of those signs with organic changes, and with the symptoms and history of the case, that Laennec's imperishable fame is founded. Time has shown, that his principles of diagnosis were not the bagatelle of a day, or the brain-born fancy of an enthusiast; the use of which, like the universal medicine, was to be soon forgotten, or remembered only to be ridiculed. It has shown, that the introduction of auscultation, and its subsidiary physical signs, has been one of the greatest boons ever conferred by the genius of man on the world. A new era in medicine has been marked by a new science, depending on the immutable laws of physical phenomena, and—like other discoveries founded on such a basis—simple in its application, and easily understood. A gift of science to a favoured son: not, as was formerly supposed, a means of merely forming a useless diagnosis in incurable disease; but one by which the ear is converted into the eye; the hidden recesses of visceral disease opened to the view; a new guide in the treatment, and a new help in the early detection, prevention, and cure, of the most widely spread diseases which afflict mankind.\*]

## CHAPTER IV.

### DISEASES OF THE LARYNX AND TRACHEA.

#### SECTION I.—ACUTE LARYNGITIS.

*Not described by Cullen.*—I shall now proceed to consider inflammation of the commencement of the air-passages, properly so called;—inflammation of the larynx,—“laryngitis.” This disease is not mentioned by Cullen. He speaks of “*cynanche trachealis*,”—he speaks of the windpipe, and of croup; but not of this particular inflammation situated in the larynx. Indeed, so little was it formerly attended to, that when two or three physicians died of it, some years ago, it was considered almost a new disease; but, on looking into old writers, we find it well described.

\* Dr. Stokes's “Treatise on Diseases of the Chest,” Section I; Pages 24, 40, and 41.

Morgagni and others have described this disease;—proving that it is not new to medical men;—but, from there being no “outward and visible sign,” in some cases, it was called “*angina occulta*,” to distinguish it from common sore-throat, which they called “*angina manifesta*.”

*Symptoms.*—In this affection, there is hoarseness or whispering; and, indeed, almost suppression of the voice. The breathing also is hoarse, loud, and rough. The inspirations are long. There is great dyspnœa; and, besides the constant difficulty of breathing, there are occasional paroxysms of dyspnœa, in which every muscle of the body comes into play; the eyes start; and the person looks as if he were being hanged. Such is the state of the parts, that there is also frequent orthopnœa (from *oppos*, *erect*; and *πνῶν*, *breathing*);—that is to say, the person cannot breathe unless he be erect. From the great difficulty of breathing, the face is pale and ghastly; the lips are pale and livid; and perhaps the face and throat are swollen. There is pain felt in the throat, exactly in the situation of the larynx; and on pressing the larynx, we are sure to find it tender. Sometimes, but not always, there is redness and swelling of the face.

Sometimes there is swelling and redness of the fauces, of the “*velum pendulum palati*,” and uvula; and, indeed, of the tongue. Occasionally, “*cynanche tonsillaris*” coexists with laryngitis. Indeed, it *frequently* does so;—the inflammation commencing in the tonsils, and spreading into the larynx. The epiglottis is very often swollen. The epiglottis is a part of the larynx;—so much a part that, in many anatomical books, it is enumerated with the cartilages of the larynx. Sometimes there is cough,—but not always. Sometimes, too, there is difficulty in swallowing. In the function of deglutition, the larynx is raised and brought forward; and if a part of the larynx so much pressed upon be inflamed, of course there is a difficulty of deglutition;—*dysphagia*, as it is called. There is also expectoration of viscid mucus; for the inflammation, being seated in a mucous membrane, will (of course) affect the secretion of that membrane. The tongue, likewise, is very foul;—from the inflammation taking place in its neighbourhood. These are the *local* signs; and they are those of inflammation;—redness, swelling, heat, and pain.

*General Symptoms.*—From the disturbed function, there are also *general* symptoms. There are thirst, heat, extreme restlessness, and great anxiety. The difficulty of breathing must occasion great restlessness, and extreme anxiety. The pulse is rapid; and there is at last a clammy sweat. The pupils, too, at last become dilated; and the patient keeps his mouth constantly open. The difficulty of breathing occasions, I presume, such an accumulation of blood in the head, that more or less compression exists; and the pupils consequently become dilated; and the patient, from the want of breath, opens his mouth, gasps, and makes an effort to take in all he can.

*Duration.*—This disease, when acute, lasts only about three or four days:—not including the previous days, on which there may be “*cynanche tonsillaris*,” but reckoning from the time when the larynx becomes actively inflamed. Death sometimes occurs very suddenly. A violent spasm takes place; and the patient is quickly destroyed.

*Most Common in Adults.*—This is a disease which occurs almost always in adults. Children have *croup*,—inflammation of the *windpipe*; but when inflammation of this violent kind attacks adults, it affects the tube higher up;—it affects the *larynx*; and it has, therefore, been called “the croup of *adults*.”

*Morbid Appearances.*—After death, we find the mucous membrane of the glottis, and of the posterior part of the epiglottis especially,—perhaps the mucous membrane of the whole of the larynx,—red, swollen, and œdematous;—swollen not merely as mucous membranes are when inflamed, but from effusion into the subjacent cellular membrane. The “*rima glottidis*” is found to be nearly closed; and this would appear to be the great source of dyspnœa;—the œdematous state of the parts, which produces nearly a closure of the “*rima glottidis*.” Sometimes the disease proceeds so far as to cause an effusion of fibrin;—so that, notwithstanding

the disease is an affection of the *mucous* membrane, fibrin is poured forth,—just as in a *serous* membrane; and sometimes we find a quantity of pus;—or, at least, of puriform fluid. Occasionally the tonsils are not merely red, as I stated, but even ulcerated; and occasionally the pharynx and the trachea below, and even the bronchia, are also inflamed. We are not, therefore, to expect one uniform appearance in the disease.

*Pathology of Laryngitis.*—We find the essence of it, in all cases, to be a violent inflammation of the larynx; and, in general, an œdematous state of the “rima glottidis” and the parts around; but frequently there is inflammation higher up, about the tonsils and the “velum pendulum palati;”—perhaps, also, inflammation of the pharynx. With respect to the quality of the fluids, they will vary from thick mucus to puriform fluid, and even up to fibrin; but that which we particularly notice, is an œdematous state of the submucous tissue. All these appearances are nothing more than we might expect. The œdematous state, which perhaps is fatal, is nothing more than what occurs when the cellular membrane is inflamed in any other part of the body. When inflammation is situated near cellular membrane, it secretes abundantly. In violent inflammation of the skin, the cellular membrane secretes to a great extent; so that there is more or less œdema; and the same thing occurs here; but from the circumstance of the parts being air-passages, and the inflammation being in the narrowest part of the passage, it is often dangerous. The same occurrence, situated a little higher in the pharynx, produces only a trifling inconvenience.

*Causes.*—The disease begins from a catarrh. The person has a common cold; and the latter generally arises from cold and wet. The application of cold alone will produce the disease; but it usually results from a union of the two, applied either to the throat or to the feet. A few days after exposure, the patient has great hoarseness; and then pain in the larynx comes on. Sometimes it does not arise from a common cold; but, as I have mentioned already, a pretty brisk inflammation of the tonsils takes place, and it spreads from them. Occasionally, too, it takes place suddenly; but I have seen it in the middle of a chronic disease. There is no part of the body which can be inflamed *chronically*, that may not become the seat of *acute* inflammation; and therefore this occurrence may take place in the throat. When there is a syphilitic sore-throat, or a chronic affection of any kind, patients may suddenly experience great difficulty of breathing, and be in the greatest danger from active acute laryngitis.

[Acute inflammation of the larynx has been brought on by swallowing scalding or corrosive liquids. By the convulsive action which these excite in the throat, they are in part thrown on, and even into the glottis. Children accustomed to drink from the mouth of a tea-kettle or tea-pot, have often attempted to do this when these vessels contained scalding water; the result has been violent inflammation of both pharynx and larynx. Instances of this accident were first recorded by Dr. Marshall Hall. Mr. Porter observes, that when a person attempts to drink (by mistake) a corrosive liquid, a similar convulsive action takes place;—closing the pharynx, and throwing the offending matter violently backwards through the mouth and nostrils, under the epiglottis; and thus this accident becomes a cause of acute inflammation of the larynx. Mr. Ryland has, with good reason, placed the inhalation of flame, or of very hot air, among the causes of acute inflammatory injuries of the larynx. Persons who die from severe burns, if it be only about the head and face, generally suffer from severe dyspnœa; and the mouth and larynx are found in a highly inflamed and congested state: these effects he very rationally ascribes to the great heat of the air inhaled at the moment of the conflagration. The inhalation of very acrid vapours, might possibly have the same effect. As exciting causes of asthenic laryngitis, erysipelas, scarlatina, small-pox, and measles, may be mentioned; and we may add, that inflammation of the tongue from the excessive use of mercury, and diffusive cellular inflammation from punctured wounds, have been known to extend to the cellular tissue of the larynx, and cause death.]

M. Bayle and Dr. Tweedie have noticed, that œdematous laryngitis sometimes suddenly supervenes, without any obvious cause, during and after typhoid fevers. It occurs, also, not unfrequently, in the course of chronic disease of the larynx, and is sometimes the cause of death in these cases. We<sup>a</sup> have known it to come on, and hazard life, in a patient with aneurism of the arch of the aorta; before the tumour had well shown itself outwardly.

Habitual intemperance, long courses of mercury, and frequent and long-continued exertions of the voice, are supposed to predispose persons to attacks of laryngitis. Except in cases of scarlatina, measles, and small-pox, and of the accidents before alluded to, laryngitis never attacks children; and, of those advanced in life, Dr. Cheyne states that it most frequently occurs in such as are liable to indigestion connected with a disordered state of the liver. In most instances, the subjects of it had previously been liable to sore-throat.

*Diagnosis.*—The symptoms of acute laryngitis, are generally sufficiently characteristic to separate it from other diseases affecting the breathing. The stridulous or hissing inspiration, heard most distinctly at the larynx (which is drawn down at each act), the seat of the sensation of pain or constriction at that part, often the visible condition of the epiglottis, and the absence of pectoral signs, suffice to distinguish it from diseases of the chest. Abscesses external to the larynx, and compressing it, may cause difficulty of breathing and swallowing: sixteen years ago we<sup>a</sup> saw a fatal case of this kind, which was mistaken for laryngitis; until the first incision of the throat after death gave issue to a quantity of pus, which had formed among the numerous muscles of the tongue and larynx. Careful examination will generally distinguish these cases by the partial or general swelling at the upper part of the neck, often with tenderness and an inability to open the jaw. Mr. Porter thinks that they differ from those of laryngitis in the breathing, although obstructed, being less sibilous, and more gradually oppressed; and in the diminished mobility of the larynx, when pressed from side to side against the spine. We<sup>a</sup> should conceive, that the absence of the peculiar cough and hissing hoarseness of laryngitis might, in some cases, better assist the diagnosis. Spasmodic affections of the larynx, may generally be distinguished by the complete absence of fever, and by the suddenness of the attack; but they may not be so easily distinguished from the œdematous laryngitis supervening on chronic diseases, which is, in effect, generally combined with spasm: still, in this case, there is usually a previous slight access of fever, and increase of the chronic symptoms. Spasm of the glottis is a very rare affection in adults, and occurs only in hysterical or highly nervous subjects.

*Prognosis.*—Laryngitis has been considered, by Dr. Cheyne and others, to be the most fatal of all the inflammations. Of seventeen cases observed by Bayle, during six years, only one recovered. Of twenty-eight cases collected (from various authors) by Mr. Ryland, ten recovered; which he justly considers to be above the average. In most of the fatal cases, death took place between the first and the fifth days. The prognosis must, therefore, in all cases be unfavourable; and the more so, as the disease has lasted longer, and with progressive increase of the difficulty of breathing. When the face loses its colour or becomes livid, and the faculties obtuse, from the circulation of black blood, the danger is extreme. On the other hand, decrease of the difficulty of breathing and of swallowing, a returning freedom of expectoration, with an improved expression and colour of the countenance, give rational hopes of recovery.<sup>b]</sup>

*Treatment.*—This is a disease in which, if in any, it is necessary to be most active in treatment. No trifling practice is admissible here. We cannot trust to nature; nor can we trust to medical measures alone;—for it is necessary (in cases which last any time, and which become very severe) to use the combined force of medicine and surgery.

*Bleeding.*—The first thing to be done is, undoubtedly, to bleed freely in the

<sup>a</sup> Dr. C. J. B. Williams.

<sup>b</sup> "Library of Medicine;" Volume 2; Pages 42 and 43.

arm;—to make the patient faint, if we can; and then to cover the throat with leeches. I am taking it for granted that the patient is able to bear it. The disease may attack a person with syphilitic sore-throat; and he may be worn out with mercury and disease; so that we may not be able to bleed in the arm; but still, in most cases, I am satisfied it would be best to set the patient upright, and take as much blood as he can spare;—be it three, or four, or twenty, or thirty ounces; and to produce fainting, if possible. There can be no rule for the quantity; but it may be necessary to take thirty or forty ounces, and to apply from six to thirty leeches; according to the age and strength of the patient. After the leeches, a poultice for some time may be a good application; and then, after all, a blister, if we please; but not earlier.

*Mercury.*—In this disease mercury is recommended, even by those who do not ascribe any active power to mercury in general. It is of the highest importance to get the mouth tender as early as possible; and therefore we must not wait a couple of days for salivation to take place. A solitary case of this disease is recorded in the “*Medico-Chirurgical Transactions*,”<sup>a</sup> where ten grains of chloride of mercury were given every two or three hours, till ptyalism was produced; and as soon as the patient began to spit, the affection ceased. I have treated many cases of the disease in this manner; and with the greatest success. In a case of this kind, it will not do to give a few grains of calomel night and morning; for the patient is in constant jeopardy;—we are never sure of his life, from hour to hour. It would be good practice to rub in mercury on the extremities. If we exhibit mercury by the mouth, it is necessary to give it in large and repeated doses. I will not say any thing about the dose; because if we know that the patient is soon affected by mercury, a small quantity will do. I only state that it is necessary to get the mouth sore, in one way or other, as soon as possible.

*Bronchotomy.*—If the patient be in great danger,—if his attacks of difficulty of breathing come on frequently, it will not be right even to wait for ptyalism; but it will be requisite to make an opening into the throat;—so as to enable the patient to live till the mercury produces its effects. Bronchotomy,<sup>b</sup> is absolutely necessary, in many cases of this disease. By opening the air-passages below the part inflamed, instantaneous relief is afforded; and the patient will live so much the longer. This cannot have the effect of curing the disease, but it has the effect of enabling the patient to live longer;—to live, therefore, till we adopt other means to cure him. I have had (to speak as a pathologist) some very *beautiful* cases of this description; where the combined force of the two great divisions of the profession, has most decidedly saved the patient’s life; but where neither would have done alone. A mere opening of the larynx will not cure the inflammation, and the patient may die before the mercury can have any effect; and, therefore, it is necessary to watch the patient constantly; and if the symptoms decidedly grow worse, the operation ought to be performed without delay. It is an operation which, if properly performed, can do no harm. The dyspnoea arises, as I have said, from an œdematous state of the “*rima glottidis*,” and if we enable the patient to breathe notwithstanding that, as the inflammation subsides the œdema goes down. The paroxysms of difficulty of breathing, clearly arise from spasm; and if an opening be made below, so that the patient can breathe through it, the disease may occasion as much spasm as it chooses;—the patient is safe.

*Spasmodic Closure of the Larynx.*—The least pressure in these parts will occasion spasmodic difficulty of breathing. In the “*Medico-Chirurgical Transactions*,”<sup>c</sup> Mr. Lawrence describes the case of a person, who had attacks of dyspnoea, from very slight pressure of an aneurism of the “*arteria innominata*. The direct diminution of the trachea by the tumour, was found to be very inconsiderable; but it was sufficient to produce irritation, and to cause violent attacks of spasmodic dyspnoea.

But, independently of this œdema and tension of the parts, the inflammation of

<sup>a</sup> Volume 9; Page 31.

<sup>b</sup> From βρογχος, the windpipe; and τεμνω, to cut.

<sup>c</sup> Volume 6; Page 227.

the membrane itself, will throw the parts around it into violent spasm;—just as occurs in inflammation of the urethra and bladder. When inflammation exists about the larynx, the person is continually seized with a violent difficulty of breathing, without any pressure, but merely from the irritation; and many persons, without any inflammation about these parts deserving the name of “laryngitis,” will die in a moment. I have seen several cases of persons, who have been seized with a sudden difficulty of breathing, when they were supposed to have only a common sore throat; some of whom have died in the course of three or four hours, and some in a minute. When inflammation exists in the fauces, and extends to the glottis, without descending to the larynx and producing laryngitis, the person may be seized with spasmodic difficulty of breathing, and die instantly. I once saw a young man, who, in consequence of a fright, became very nervous, and therefore liable to spasmodic diseases. He merely caught a common sore throat, for which six leeches were applied; and, while the ward was full of medical men, a violent spasm seized his throat, and he died instantly. Every thing was done for him that could be done; but he was quite dead. I have seen several patients with more decided inflammation than this, (but still not with inflammation deserving the name of “laryngitis,”) who have died in a moment. When, therefore, there is laryngitis, we may well suppose how dangerous the case is; and how necessary it is to be active in the highest degree. Whenever a patient becomes very hoarse, and we hear his voice hissing (“sibilous”) through the larynx, and find the tube is tender on pressure, alarm should instantly be taken, and the disease treated actively:—although the patient may make no particular complaint himself; and although, on looking into the throat, we cannot discover any thing particular.

## SECTION II.—CHRONIC LARYNGITIS.

*Symptoms.*—A much more common disease than this, however, is *chronic laryngitis*; an affection of which many cases occur. This species of the disease is attended by a very hoarse cough, and likewise with a hoarseness of the voice; and sometimes the person, both when coughing and talking, makes a sort of crowing sound. The alterations in the voice are very great. There is hoarseness, roughness, squeaking, and crowing; and sometimes it is nearly suppressed. The cough, too, varies in the same way. Sometimes it is very hoarse; and sometimes very shrill. The respiration in chronic laryngitis, is occasionally hissing; but not necessarily so. It is observed in *most* cases; but by no means in *all*. There is a copious discharge of mucus, and sometimes of pus. In these cases, I have always observed pain on pressure. If the lungs be sound, we must learn that chiefly by means of auscultation;—by ascertaining that the sounds of the chest are healthy; and that there is no pectoriloquy. However, it is sometimes difficult, when the voice is nearly suppressed, to make up one's mind on the subject. Some say they can tell it as well when the voice is suppressed, as when it is not; but I confess I have not attained that perfection. This disease may occasion great emaciation; and from that circumstance, as well as on account of the discharge of mucus of a puriform character, patients may easily be supposed to be in a state of pulmonary consumption; and it is a fact, that the disease does sometimes coexist with “*phthisis pulmonalis*.”

*Diagnosis.*—[The most characteristic signs of chronic laryngitis, are the permanent change of the voice, and the peculiar cough before described; with hissing breathing, and pain or tenderness in the larynx, when these happen to be present. Except in syphilitic cases, where the fauces are also diseased, little is to be learnt from examination of the throat; for it is impossible to see or reach further than the epiglottis, and to get a view of this is a matter of difficulty. Neither is crepitation felt on pressing the larynx to be depended on; for, according to Trousseau and

Belloe, this may be produced in a healthy larynx. Dr. Stokes describes, as a stethoscopic sign of chronic laryngitis, a harshness in the sound of the air passing through the larynx,—giving the idea of a roughness of surface, perceptible even when the breathing is not distinctly stridulous. In a few cases he observed (above the thyroid cartilage) a rhonchus, like the sound of a valve in rapid action, combined with a deep humming. We<sup>a</sup> much question that the latter sound was seated in the larynx; for such a sound is often produced in the jugular veins. When the laryngeal constriction is considerable, the peculiar sound of the passage of air through it will sufficiently distinguish it; and where it is slight or altogether absent, laryngeal disease may yet be known as the cause of the cough and other symptoms, by the negative indications of the thoracic organs;—the sound of percussion and of respiration being good throughout the chest. But pulmonary tubercle is very commonly conjoined with laryngeal disease; and the two affections are apt to disguise each other. The noisy laryngeal respiration, and the absence of the voice, may destroy the chief distinctive signs of phthisis in its early stages; but as the disease advances, the dulness on percussion, and perhaps cavernous rhonchus in some part of the chest,—particularly under a clavicle or scapular ridge,—with a more copious purulent expectoration, night-sweats, and more rapid emaciation, sufficiently announce this most destructive complication. When the breath and sputa in laryngeal disease are very fetid, it may be suspected that some part of the cartilages is dead. This is generally the case where chronic abscess opens outwardly, about the thyroid cartilage.

*Prognosis.*—The milder and simpler forms of chronic laryngitis, are by no means incurable; in fact, they generally yield to judicious treatment: and were it not for their liability to exacerbations from acute œdematous inflammation, and to complications with pulmonary diseases, they could hardly be called dangerous. Both these destructive complications may be apprehended when the disease has continued long, with increasing severity of symptoms of the voice and respiration, with a change of the cough from dry and ringing to loose and undivided, with increasing purulent expectoration, and particularly if the disease has resisted treatment. If, from the history of the individual, there be any suspicion of a scrofulous tendency, and particularly if symptoms of pulmonary disease,—such as slight cough, shortness of breath, pains in the chest or shoulders, quickened pulse, &c.,—preceded those of the laryngeal affection, the prognosis is unfavourable; and if there are found any physical signs of phthisis—such as dulness under a clavicle,—the case of the patient must be considered almost hopeless. Factor of the breath and sputa, implying mortification of the cartilages, is also very unfavourable; but it is more probable that the dead portions of these may be thrown off, than that tuberculous disease of the lung combined with a laryngeal lesion can be cured. In all doubtful cases, particularly those of a syphilitic origin, the state of the general health and strength, as well as the degree of the local affection, must be duly taken into account, in estimating the probable issue of the case.<sup>b</sup>]

*Morbid Lesions.*—After death from this disease, we find the common results of chronic inflammation. The mucous membrane is frequently thickened,—frequently indurated,—frequently granulated;—exceedingly rough, and containing numerous little cavities (if I may so call them). Frequently it is ulcerated. The same appearances very often extend along the trachea.

*Treatment.*—In the treatment of this *chronic* form of the disease, we are by no means so successful as in that of the *acute*. In fact, the treatment, for the most part, is very unsatisfactory. The best method we can adopt, is the repeated application of leeches, and subsequently of blisters. The internal exhibition of mercury, too, is of the greatest use. If the disease be a *scrofulous* inflammation, however, of course mercury will do no good, but rather make things worse. It is best, in almost all cases, to give it a fair trial;—taking care not to hurt the constitution;

<sup>a</sup> Dr. C. J. B. Williams.

<sup>b</sup> "Library of Medicine;" Volume 3; Page 49.

but to make the mouth moderately sore, and to keep it so;—to treat it as a mere chronic inflammation. It will very frequently subside; but far *more* frequently, I believe, the treatment is very unsatisfactory.

On account of the sufferings of the patient, and the harassing cough, it is often necessary to give narcotics, to procure sleep. Conium answers exceedingly well. Some have found relief from the inhalation of the fumes of tar; and others from the inhalation of chlorine;—either by diffusing it through the apartment of the patient, or making him breathe through water in which a quantity of chlorine exists. But it is very necessary, in all these cases, to proceed cautiously. Tar-fumes, chlorine, and many of these things, will produce very great irritation, even in small quantity; and therefore it is right always to begin by impregnating the water, or the apartment, very *moderately*; and, if it produce no irritation, then we may go on to a great extent.

Some have recommended, as internal medicines, copaiba and cubebs; because they have done good in irritation of another mucous membrane. I have not been satisfied with these medicines; but as they are recommended, I mention them. Some have recommended the application of lunar caustic. A solution of nitrate of silver is made, and a sponge, dipped into it, is pressed down to the “rima glottidis;” so as to produce a new action there, and lessen the morbid sensibility;—with the hope, that the same good change which is observed at the spot at which the nitrate of silver is applied, may spread downwards. I have known this remedy employed; and, as may be imagined, fruitlessly; but if the disease were situated merely at the “rima glottidis,” good would be done by it. I have no experience of it myself; but I have seen cases in which I understood it had been employed without any harm.

[MM. Trousseau and Belloc place much confidence in medicaments applied directly to the diseased part; and some of those which they recommend are of a very energetic kind;—such as nitrate of silver, corrosive sublimate, sulphate of copper, &c. They may be applied either in solution or in powder. The solution which they have found most effectual, is that of nitrate of silver, in the large proportion of from one to two parts in four parts of distilled water. This solution may be applied to and behind the epiglottis, by a small roll of paper bent at its moistened end. A more effectual mode is with a small round piece of sponge, fixed to a long rod of whalebone bent, at an inch from the sponge, to an angle of eighty degrees. The patient’s mouth being opened wide, and the tongue pressed down with a spoon, the sponge is passed to the top of the pharynx; as soon as it reaches the fauces, a movement of deglutition takes place, which carries the larynx upwards, at which moment the sponge is brought forward, and squeezed under the epiglottis, and the solution freely enters the larynx. Convulsive cough, and sometimes vomiting ensue; but the application causes no pain. A less disagreeable mode of applying the solution, is by a small silver syringe, filled one-fourth with the solution, and three-fourths with air. To this is affixed a tube five inches long, bent at the free end; which being carried beyond the epiglottis, the syringe is forcibly discharged; and, in consequence of the air in it, throws the solution, not in one stream, but in a fine shower; part of which enters the larynx. The patient is then made to rinse his mouth with, and swallow, salt water, or water acidulated with muriatic acid, which decomposes the remains of the nitrate; the same precaution should be used, where this agent is applied in substance. MM. Trousseau and Belloc found this application (which they term “cauterization”) highly beneficial in several cases of chronic laryngitis. In cases of aphonia, probably dependent on relaxation rather than inflammation, it effected a cure in a few days; in some worse forms of the disease, with probably ulceration of three or four years’ standing, its repeated application during five or six weeks was successful; and it produced considerable temporary improvement, in three cases which proved afterwards to be tuberculous. Solid substances may be applied to the larynx in powder by insufflation; as recommended by Aretæus for “angina maligna.” The powder is put into one end of a reed or glass tube, and the other is carried back as far as possible

into the mouth: after a full expiration, the patient closes his lips around the tube, and inspires suddenly and forcibly through it; by which some of the powder is carried into the larynx and trachea. The cough which is excited should be restrained as much as possible;—to prevent the too speedy expulsion of the medicine. The powders used by MM. Trousseau and Belloc, are subnitrate of bismuth, which may be used pure with safety and advantage in most forms of chronic laryngitis, even that accompanying phthisis; calomel with twelve times its weight of sugar; red precipitate, sulphate of zinc, and sulphate of copper, each of which must be mixed with thirty-six times its weight of sugar; alum with twice its weight, and acetate of lead with seven times its weight of sugar; and nitrate of silver with twenty-two, thirty-six, or seventy-two times its weight of sugar. The last is said to be most effectual in erythematous laryngitis, with erosions or ulcerations. Calomel and red precipitate have proved beneficial in ulcerations, whether syphilitic or not; but they should not at first be repeated oftener than twice or thrice a week. The others may be used twice or oftener daily, according to the nature of the case. The powders should be impalpably fine: the least roughness or perceptible fragment of a crystal excites such efforts to cough, as insure the expulsion of the powder. This description of the treatment of MM. Trousseau and Belloc, is taken from an abstract in the “British and Foreign Medical Review;” and appears to be well worthy of the attention of British practitioners;—proving the safe direct application of powerful agents, which (as in external diseases) are likely to improve the action of the diseased parts.<sup>a</sup>]

### SECTION III.—CROUP.

*Synonymes.*—Acute inflammation, of a very violent description, when it attacks the larger portion of the air-tubes, is situated (for the most part) lower down in children than when it occurs in adults. That intense, violent, adhesive inflammation,—inflammation, at least, causing a portion of fibrin to be thrown out,—which attacks adults, usually affects the larynx; so that *laryngitis* is the disease of adults; and the disease of children, corresponding with this, is *croup*;—“*cynanche trachealis*,” or (more properly) “*tracheitis*.” The latter term is the most simple; and every body knows what is meant by it. The disease has been called “*angina trachealis*,” because there is a quantity of lymph formed. In this country it is called “*croup*,” in the east, I understand, it is called “*roop*,” and perhaps it is so in other places.

*Symptoms.*—This disease is marked by a rough, clanging, ringing cough;—a cough which gives the idea of sound conveyed through a small brass pipe. Besides this cough, if the disease be severe, there is hissing (“*sibilous*”) respiration; but it is chiefly in the inspiration that it is heard. It is harsh, rough, shrill, or hissing;—there being various modifications. The voice, too, is either harsh, crowing, or nearly suppressed. There is a difficulty of breathing; and this is felt particularly during inspiration. These are the most common symptoms. There is no difficulty in swallowing; no pain in the throat, except at the lowest part; no pain in the larynx (where there is always pain or tenderness in laryngitis); but in croup, at the lowest part of the throat, where the trachea exists, there is frequently pain on pressure. The expectoration is mucous; sometimes mixed with fibrin and shreds of lymph. As this is a violent disease, there is violent pyrexia. During the first stage the face is flushed, the pulse is rapid, and there is great anxiety of countenance. Sometimes the peculiar clanging cough is heard for some days before the child is ill enough to show its complaint; so that many mothers have been surprised, on being told by a medical attendant (who has accidentally been in the house, and heard this peculiar cough,) that the child was in danger.

*Varieties.*—[We may meet this disease under two essentially different forms.

<sup>a</sup> “Library of Medicine,” Volume 3; Pages 50 and 51.

It may occur, in the first place, as a primary, idiopathic, and active inflammation of the respiratory mucous membrane; in which case the accompanying fever is symptomatic. In the second place, we have it *preceded by fever*, and the formation of false membranes in the pharynx and the cavity of the mouth; which membranes, by extending downwards into the glottis and larynx, produce the symptoms of croup, in the advanced stage of another and totally different disease.

The greatest confusion has arisen, from authors not carefully separating these two forms of disease, in their descriptions of croup, and in their opinions as to its treatment. For the sake of clearness, I<sup>a</sup> shall arrange their symptoms in pairs of opposite characters;—distinguishing the affections by the name of “primary” and “secondary” croup.

## PRIMARY CROUP.

## SECONDARY CROUP.

- |  |   |
|--|---|
| 1. The air-passages primarily engaged.   | 1. The laryngeal affection <i>secondary</i> to disease of the pharynx and mouth.                                |
| 2. The fever symptomatic of the local disease.   | 2. The local disease arising in the course of another affection, which is generally accompanied by fever.       |
| 3. The fever inflammatory.   | 3. The fever typhoid.   |
| 4. Necessity for antiphlogistic treatment, and the frequent success of such treatment. | 4. Incapability of bearing antiphlogistic treatment; necessity for the tonic, revulsive, and stimulating modes. |
| 5. The disease sporadic, and in certain situations endemic, but never contagious.      | 5. The disease constantly epidemic and contagious.  |
| 6. A disease principally of childhood.   | 6. Adults commonly affected.  |
| 7. The exudation of lymph from the glottis, from below upwards.                        | 7. The exudation spreading to the glottis, from above downwards.  |
| 8. The pharynx healthy.  | 8. The pharynx diseased.  |
| 9. Dysphagia either absent or very slight.   | 9. Dysphagia common and severe.   |
| 10. Catarrhal symptoms often precursory to the laryngeal.                              | 10. Laryngeal symptoms supervening without the pre-existence of catarrh.  |
| 11. Complication with acute pulmonary inflammation common.                             | 11. Complication with such changes rare.  |
| 12. Absence of any characteristic odour of the breath.                                 | 12. Breath often characteristically fœtid.  |

From the consideration of these characters, we must admit that, independently of minor differences, there is a broad line of distinction between these affections of the throat. In the one, the windpipe is the seat of an idiopathic, primary, and highly inflammatory disease; while in the other, its affection is accidental, inconstant, and secondary to a diseased state of the pharynx; which, in its turn, is either symptomatic of, or closely connected with, a morbid state of the whole system. Yet, as I<sup>a</sup> said before, the want of an accurate distinction between these affections, has led to the greatest misapprehension; and we see British physicians ridiculing the opinions and treatment of the continental practitioners, and *vice versa*;—the error, all the while, arising from the confounding of two essentially different affections. In the croup, as described by British authors, the utility of antiphlogistic treatment has been tried by experience.<sup>b</sup>

*Duration and Progress.*—The disease may last from twenty-four hours, to three or four days, or even *several* days; and the child may either die completely exhausted, or be suddenly cut off in a moment, by spasm. Just as *death* sometimes occurs suddenly, so does *amendment*. Generally, patients recover by *degrees*; but sometimes they recover very *rapidly*,—almost *suddenly*. When recovery is exceedingly slow, shreds of fibrin are perhaps spit up for several weeks.

*Morbid Appearances.*—On examination after death, we find (of course) redness of the trachea; and such is the intensity of the inflammation, that lymph lies upon the red membrane;—sometimes forming a complete tube, and even extending into the bronchia. Besides this tube of lymph, which is so continually seen, we fre-

<sup>a</sup> Dr. Stokes.

<sup>b</sup> Dr. Stokes, on Diseases of the Chest; Part 1; Section 3; Pages 205 to 207.

quently observe a quantity of puriform, and even bloody fluid, in the air-tubes. When we open an inflamed serous membrane, we always see lymph lying upon the affected part; but besides that, we always see more or less turbid serum, even so thick and yellow as to approach to pus; and sometimes there is pus. So in a mucous membrane, when it is inflamed very intensely, besides fibrin, there is a quantity of thin fluid, inclining more or less to pus; and at last actual pus. There is also a bloody fluid.

*Age at which it occurs.*—This disease occurs chiefly in children, between weaning and puberty. It is occasionally seen in infants at the breast, but more frequently not till they are weaned; and Professor Home, of Edinburgh, says, that the sooner children are weaned, the sooner they are liable to it. They have more experience at Leith than we have here; and observations, therefore, are more easily made there. It chiefly affects those of a full habit of body.

*Causes.*—The cause is undoubtedly, in almost every instance, cold and wet. It occurs, therefore, more frequently in winter and spring, than at other times; and if it occur in summer, it is generally when a damp evening has succeeded to a hot day. It is seen most frequently in a situation near the water side;—in fact, in all damp situations. It is more frequent, too, in northern than in southern latitudes. It is sometimes epidemic;—that is to say, a great number of children, in particular seasons, are affected with it. An endeavour has been made to pervert the word “*epidemic*” from its common original meaning;—“that which attacks people at large.” In that sense we have a peculiar signification; so as to distinguish between *epidemic* and *contagious* diseases. But *contagious* diseases may be *epidemic*;—not from this cause or that; but merely because they extend temporarily over a whole district at once. But although this disease is frequently epidemic, I cannot believe that it is ever contagious;—at least, I have never been able to satisfy myself that such was the case. It certainly does often affect more than one in a family at once; but this may only arise from all the children in the family being exposed to the cause at the same time; and from another circumstance,—that there is a constant tendency to it; and therefore children in the same family may be supposed liable to the same disease. Now and then, a peculiarly striking circumstance takes place; and we are inclined to believe that the disease must be contagious; but I think mistakes are frequently made in the case of croup. I will not say that it is *never* contagious, because I have not seen every circumstance that other people have; but, from what I have seen and read, I cannot persuade myself that it is contagious. It is a fact, that many children have it in the same neighbourhood; but then they have been visited with the same vicissitudes of atmosphere; and the occurrence may thus be explained. And when it occurs in the same family, this fact might explain it;—together with the additional circumstance, that all their constitutions are predisposed to the same disease. I know, too, that several children in a family will have it, but at different times; and some of the children in a family will be sure to have it; and therefore I presume there is a constitutional tendency to it;—just the same as in inflammation of other parts. Professor Dupuy says, that it once occurred in dogs at Alfort, and that the same appearances were observed in them, as in human beings.

*Nature.*—[The nature of croup has been the subject of much discussion. In Dr. Copland’s “*Dictionary*,”<sup>a</sup> the reader will find an account of the various opinions which have been held respecting it. Our limits do not permit us<sup>b</sup> to enter into these; and we shall only give that view which, in the present state of our knowledge, seems most tenable; and which best comports with the whole history of the disease, and the effects of remedies on it. These indubitably prove true croup to be essentially an inflammatory disease of the air-passages, especially of the trachea and larynx. But why does it differ from the catarrhal or bronchitic inflammations which we find to occur in the same parts? Many authors seem to consider its seat to be the same as that of catarrhal inflammation, and that the

<sup>a</sup> Volume I; Part 2; Page 449.

<sup>b</sup> Dr. C. J. B. Williams.

difference of its product (lymph instead of mucus) is to be ascribed to the early age at which it most frequently occurs. But this is insufficient: for at the same age, we meet with bronchitis affecting every portion of the air-tubes, yet without constituting croup. Others again, and among them Dr. Copland, refer the peculiarity of the product to an excess of albumen in the blood;<sup>a</sup> but even this, although it probably has a share in determining the amount of membranous or other solid formations within the air-tubes, does not alone seem sufficient to cause it; nor can it be ascribed to the intensity of the inflammation; for although the albuminous effusion is generally thickest and most tough in *sthenic* cases of croup, yet it is pretty abundant in *asthenic* cases;—so much so, that Andral and Gendrin consider plastic inflammations of mucous membranes to be rather of the sub-acute than of the most acute kind. To say that the inflammation is one of a specific character, throws no light on its nature. But does not the pathological and anatomical history of croup seem to point out, that the seat of its inflammation is deeper than that of bronchitis? The distinct and circumscribed position of the inflammation and painful constriction in the most marked cases; its fixedness in this part,—not wandering or creeping about, as catarrhal inflammation does; the tenderness, and sometimes the swelling of the trachea and larynx externally; the nature of the product of the inflammation,—which is coagulable lymph, as from serous or cellular membrane; the thickened state of the submucous texture found after death in the earliest stages, and the tendency of this texture to suppurate in chronic cases, where the subject approaches adult age,—seem to render it probable, that the inflammation owes its peculiar character and results to its being more deeply seated, more of a phlegmonous character than mucous inflammations, and involving essentially the submucous cellular tissue. This view has not been generally held, Mr. Ryland alone distinctly inclines to it, when he remarks, that “the inflammation of croup appears, in the first instance, chiefly to affect the cellular tissue that enters into the composition of the mucous membrane, and not the muciparous follicles themselves; and the albuminous exudation is poured out by the secernent arteries of the cellular structure.” Dr. Stokes remarks, that no satisfactory explanation of the greater frequency of croup in the infant has been given; and he seeks to account for it by the general fact of the predominance in the young subject of white tissues, which reproduce their kind. This idea may lead to an explanation, but it does not set it forth; and it leaves still a mystery why croup differs from bronchitis in the same subject. But if we examine the air-tubes of young subjects, we find in them, as in other parts, an abundance of the fine submucous cellular tissue; while the mucous membrane is more fine and less complex than it becomes in after-life; when, from the continued irritations to which it has been exposed, its follicular apparatus attains its full activity and development. The blood, too, in the young subject, abounds with the plastic material of nutrition: which is more abundantly thrown out under the influence of inflammation, than in the adult. Yet, as long as the inflammation, even in young subjects, is confined to the mucous membrane, the disease is simply catarrhal or bronchitic, and its product mucous or purulent. But the inflammation may readily reach the active and vascular submucous tissue; and then it has the more fixed character of the inflammation of croup, the product of which easily transudes through the fine mucous membrane; and, as in the analogous case of serous inflammations,—which are also seated chiefly in the subserous tissue,—the product is coagulable lymph.<sup>b</sup> In adults, where the mucous membrane is more developed, and the submucous tissue less so, inflammation is less likely to reach the latter: when it does, it attacks the looser parts of the larynx, and, modified by the active mucous secretion, its product is pus, instead of lymph; or it may be confined to the tissue, and cause the œdema, thickening, or purulent infiltration of laryngitis.

The pathological history of croup is quite intelligible. The inflammation may commence in the submucous tissue, or it may have been first catarrhal; in which

<sup>a</sup> “Dictionary of Practical Medicine,” Volume 1; Part 2; Page 461.

<sup>b</sup> See Pages 96 and 108.

very common case, catarrhal symptoms precede those of croup. The inflammation immediately causes increased sensibility of the contractile fibres, and interstitial effusion in the lining of the trachea and larynx: hence results the constriction, partly spasmodic, partly from swelling of the air-tubes; and hence the croupy inspiration and cough, and the hoarseness. Afterwards lymph is poured out in a liquid state; and, becoming concrete, forms the false membrane;—another cause of obstruction to the passage of the air; both directly by its bulk, and also by the spasmodic contraction which its presence causes in the muscular fibres of the tube. The latter cause acts especially when the false membrane reaches to the larynx, and excites its very irritable muscles: in such cases, the paroxysms of dyspnoea and cough are frightfully severe and suffocating. The share which spasm has in causing the dyspnoea may be inferred from the fact, that in no case have the air-passages been found so much blocked by the albuminous secretion, as to account for the amount of the obstruction; and in many cases the constriction has appeared greatest, where little or no exudation was found after death. It must not be forgotten, however, that œdematous swelling—like that of erysipelas—may disappear after death. The separation of the concrete matter from the tube, and the prevention of its becoming permanently adherent and organized, is doubtless owing to the mucous secretion, and the continued motions of the tube. In cases where the albuminous effusion is less plastic, or the follicular mucous secretion more abundant, the matter may be liquid and purulent; and this generally takes place in the bronchitic variety. The collapse which takes place towards the fatal termination of croup is, like that in bronchitis, to be ascribed to the imperfect state of the function of respiration, and the consequent injurious effect on the vital powers. The lividity, coldness, occasional attacks of convulsions, &c., are the result of the circulation or stagnation of imperfectly oxygenated blood. From the same cause arises, also, the congestion in the lung; which may in parts take on the irritation of inflammation, and become hepatized. The emphysema occasionally detected in the lungs, is plainly produced by the violent efforts of breathing.<sup>a</sup>

*Treatment.*—The treatment of this disease must be energetic and decided;—just as I stated was requisite in laryngitis.<sup>b</sup> It would be right to bleed from the arm, or jugular vein, perhaps; and to apply a number of leeches over the throat. It is to be considered as an inflammatory disease, that must be treated briskly. I would make the same observation respecting leeches, that I have already done<sup>c</sup> respecting other inflammatory diseases of the throat. I should prefer leeches to a blister, and general bleeding to local; but I should follow up general by local bleeding. After the leech-bites had bled well, with the assistance of a poultice, I would repeat them, if necessary, and then apply a blister. There is extreme danger here; and therefore mercury should be given with the greatest freedom. Whatever disputes there are about mercury, we shall find, that in acute hydrocephalus, in laryngitis, and tracheitis, mercury is of the highest importance. Children will bear a larger quantity of mercury, in proportion, than adults; and it would be right to give a child, every two or three hours, as much as it would bear without vomiting and purging. This is a much better practice than the administration of emetics. Many cases will get well with emetics; but this will be successful in a larger number of instances. The warm-bath is useful, but not of high importance; and when the leeches have bled well, some have advised applying cold to the throat. I see no impropriety in it. The good effects of applying ice to the *heads* of children, justify the application of ice in a bladder to the *throat*; but I have no personal experience of it.

*Bronchotomy.*—Some have recommended bronchotomy in this disease; but I believe it generally fails. Bronchotomy can only be a temporary measure.<sup>d</sup> It may enable the patient to breathe well for the time; but, of course, it can have no effect upon the inflammation. If the disease were not so extensive, it might be beneficial, by giving us time to cure the affection; but, unfortunately, we frequently

<sup>a</sup> "Library of Medicine;" Volume 3; Pages 55 and 56.

<sup>c</sup> See Pages 719 and 722.

<sup>b</sup> See Page 719.

<sup>d</sup> See Page 720.

have inflammation of the trachea, larynx, and all the ramifications of the bronchia; so that it is hardly possible for the child to recover from such a mass of disease. However, bronchotomy has been tried in many cases, and failed; and I have myself employed it without success. A number of cases are recorded, where it was of no use; though it appears occasionally to have been of service. One instance (there may be more) is recorded in the "Medico-Chirurgical Transactions,"<sup>a</sup> by Mr. Chevalier; who made an opening into the trachea; the consequence of which was the discharge of a quantity of viscid bloody fluid, and the patient speedily recovered. If, after the ordinary treatment of the disease,—free bleeding, mercury, blistering, the application of cold, and (if we choose) the administration of emetics,—if we cannot make the mouth more tender, or bleed any farther, and yet the child is dying,—it would be better, if the friends would allow it, to make an opening into the trachea,—in order to give the patient a chance; but, in a great number of cases, it is a very slender chance indeed. I would not do it till I had told the parents that the child would die *without* it, and would most likely die when it was *done*; for otherwise it would be said, that we had cut the child's throat, and killed it. It is a frightful thing to make an opening in the air-passages, unless we prepare the patients (or their friends) for it.

*Seneka.*—In America, they recommend a decoction of seneka in this disease. But this is a stimulating substance; and, if it does good, I cannot believe that it is in the active inflammatory stage. When the inflammation is subsiding, and great secretion is going on, it may stimulate the parts and "brace them up;" but I have not been tempted to give the remedy in the active acute form of the disease.

*Liable to Recur.*—This disease, however, occasionally takes place without any inflammation; or, at least, any *important* inflammation. Children who have once had the croup, will frequently, on catching cold, have a crouping cough,—a little hoarseness; so as really to labour under the signs of croup; but, in such cases, the pulse is not quickened, and the child is not particularly ill. If a child have once had the croup, there is in general little fear from other attacks. If parts have been once inflamed, they soon fall into a state of inflammation again; but then it is not *active* inflammation; and sometimes the inflammation is scarcely perceptible;—the disease appearing to be merely spasmodic. I have known children have six or seven attacks of croup.

It is always safe, in these cases, to apply antiphlogistic treatment;—not vigorously, as in the first instance; but to put a number of leeches on the throat, and administer calomel once or twice a-day, and (if we choose) an emetic. These means generally dissipate the disease. I know that some patients neither require leeching nor purging; and are benefited at once by an emetic. A light inflammation has occurred; it has thrown the parts into a state of spasm; and an emetic will frequently cure it; but it is generally safer (unless we know that an emetic has cured the child before) to apply leeches to the throat, and give a dose or two of calomel. We are never sure that it is merely a spasm. There may be some little inflammation, which is increasing; and therefore it is the safest plan to begin with this treatment. If the child be not worse, but plays about, then the best thing is to give iron. Iron is a good thing to lessen morbid irritability in any part of the body. If there be inflammation it will do no good; but if there be mere morbid irritability, I know it is one of the best things. I shall have occasion to state that spasmodic cough, of a ringing character, yields most readily to iron. It is best not to begin with it; but to adopt antiphlogistic treatment for a day or two; and then we may give iron safely. The sesquioxide may be administered in treacle; or the sulphate in sugar, or tea. Children sometimes will not take it without these accompaniments.

<sup>a</sup> Volume 6; Page 151.

## SECTION IV.—ORGANIC AFFECTIONS OF THE LARYNX AND TRACHEA.

*The Larynx.*—Besides simple inflammation of the larynx and trachea, these parts are subject to various organic diseases. The larynx is frequently in a state of ulceration; and not unfrequently there are excrescences upon it;—looking, to all appearance, like warts. They are the same as warts on the genitals. Sometimes scrofulous tubercles form there. Sometimes scrofulous abscesses form in the cellular membrane; and sometimes there is cancer, and melanoid deposit.

As far as I know, in the greater number of cases, it is impossible during life to make a diagnosis between simple chronic inflammation of the larynx, and these organic changes. We find a person with tenderness of the larynx, and hoarseness;—his voice, perhaps, being reduced to a whisper; he coughs a great deal, and the cough is ragged or shrill; there is wasting, perhaps a constantly quick pulse, and tenderness;—showing, altogether, that the larynx is diseased. But I confess, I am not able to distinguish between simple chronic inflammation of these parts, and ulceration, or the existence of excrescences, or the existence of various deposits.

In the commencement of such cases, I should recommend the remedies of chronic inflammation;—leeches over and over again; blisters afterwards, if we choose; a seton in the neighbourhood of the larynx; the exhibition of mercury; and narcotics to lessen the irritation. If these things do no good,—if the patient gets worse, the corporeal strength is decaying, and the symptoms in the throat (so far from diminishing) are increasing,—then we may suspect there is organic disease; and we shall generally be right. It is only in the latter stages of the disease, that any distinction can be made. When my remedies fail, I then begin to think there is organic disease.

Occasionally the larynx is ossified. Sometimes it becomes completely ossified; and deglutition is rendered very difficult. The larynx cannot move up and down; and the passage of the throat becomes so much diminished, that the patient can scarcely swallow; and, indeed, he dies of the disease.

*The Trachea.*—The trachea, likewise, sometimes gradually becomes ossified; and all the various diseases that I mentioned<sup>a</sup> under the head of organic affections (melanosis, scirrhus, cancer, and encephaloid disease) occur here. But more frequently we have thickening of the mucous membrane, induration, considerable excrescences, and scrofulous tumours; and then the common effects of inflammation;—ulceration; the formation of abscesses; and, finally, a carious state of the cartilages.

## SECTION V.—CATARRH.

*General Character.*—This is a very slight inflammation of the larynx, trachea, bronchia, and the mucous membrane above these parts;—that portion called “the *Schneiderian* membrane” (from having been described by Schneider); and the membrane of the frontal sinuses, and even the conjunctiva of the eyes. The inflammation, in this disease, is not by any means so intense, as that which occurs in laryngitis and tracheitis; for it is an instance of common inflammation of a mucous membrane. It is, in general, a very *slight* inflammation; but it extends through the whole tract, from the conjunctiva of the eyes;—running down the lachrymal canal; and not only affecting the membrane of the nostrils, but also the frontal sinuses, the throat, the tongue, the larynx, the trachea, and the bronchia. As it affects such an extent of surface, dangerous symptoms more frequently arise

<sup>a</sup> See Pages 195 to 215.

than we are aware of. This, in medical language, is called "catarrh;"<sup>a</sup> and, in common language, we call it "a cold."

*Symptoms.*—There is a feeling, at the same time, of soreness throughout the body; and generally there is tenderness of the surface; which makes the person uneasy, if he press much upon any one part. There is stiffness, and an aching of the whole body; but it is chiefly felt in the back of the neck. There is likewise headache;—I presume, from the congestion in the frontal sinuses. Perhaps there may be more or less congestion within the head; but I should think that it arises chiefly from congestion of the frontal sinuses;—at least that the former is inferior to the latter. There is likewise chilliness, and morbid heat. The patient is chilly, and creeps towards the fire; and yet if we touch him, he is hotter than he should be. There is great sensibility of the surface; so that the least breath of air blowing upon him, causes a sensation of cold. The mind also is affected. There is heaviness of the head;—sometimes amounting to stupor; so that people are quite stupid. From the state of the conjunctiva, there is frequently stiffness and smarting of the eyes; and, from the irritation of the membrane within the nostrils, there is sneezing. There is, also, from the disturbance of the membrane, loss or impairment of smell, and apparently of taste. People say they can neither smell nor taste. I believe they can taste, although they cannot smell. Many things may be smelt as well as tasted; and these are tasted just as acutely as before. From the inflammation in the air-passages, the breath is hot; so that when we have a cold, the air expired from the lips is hot;—as though it came from a hot place. There is generally hoarseness, some cough, and a little soreness at the front of the chest. When the mucous membrane is inflamed, it is sore at the division of the trachea; and there is soreness in the situation of the larger branches of the bronchia.

*Increased Secretion.*—All the parts that I have mentioned, discharge more freely than in the healthy state. They are all covered with mucous membrane,—if the *conjunctiva* can be considered a mucous membrane; they are all in a state of slight inflammation; and therefore they are in a state of preternaturally increased discharge. The eyes "run" (called "lachrymation"<sup>b</sup>); and there is a discharge from the nose (called in Latin "distillatio;" or, as we say, "catarrhus"). The discharge from the nose, is likewise called "*coryza*."<sup>c</sup> At first, the secretion is limpid; like drops of water from a rock. It is thin and transparent; but afterwards it grows more copious and thick.

As the symptoms decline, the quantity of the secretion declines; and, as all the symptoms go away, there frequently arises a little inflammation about the mouth and nose, and an eruption; so that the common people say the cold is going, because there is a "breaking out" about the mouth. When the cold goes off, and the inflammation within ceases, it is very common for slight inflammation of an herpetic character<sup>d</sup> to take place about the mouth. During the existence of the disease, the tongue is white, the skin dry, and the urine red; and when all is declining, the urine has a lateritious sediment;—the common symptoms of inflammation. There is also a loss of appetite. The stomach is much affected in this disease. People cannot eat; and sometimes there is also an affection of the mucous membrane down the œsophagus, and in the stomach. There is heat and pain there, and tenderness on pressure. The pulse during the disease is quick.

*Progress and Duration.*—The affection has a disposition to begin above, and travel downwards; so that persons know very well which part of the mucous membrane is inflamed, at different times. When it is the mucous membrane of the frontal sinuses and nose, they say it is "in the head;"—they feel so heavy and stupid. Then that goes off, and they begin to cough. As it leaves the upper part, it generally increases in the lower; and then, after a tickling in the throat, and hoarseness, there is frequently pain down the front of the chest, and cough; and also more or less difficulty of breathing. After that the tickling of the throat is diminished. But though it travels downwards, it frequently mounts up again.

<sup>a</sup> From καταρρεω, to flow down.

<sup>c</sup> From καφα, the head; and ζωω, to flow.

<sup>b</sup> From λαχρυμα, a tear.

<sup>d</sup> See Page 110.

Sometimes people are beset with it in all parts at once; but generally, if the disease be slight, we see it travel downwards; and if a person have a relapse, it will come again above; but then people say they have "caught a fresh cold." The disease will last from twenty-four hours to some weeks; and sometimes it is the forerunner (as I stated before<sup>a</sup>) of violent inflammation of the larynx, or of the bronchia. It is often the prelude to various active inflammatory diseases.

*Causes.*—The common cause of this affection, is the application of cold—especially when united with moisture, or when the body is over-heated and perspiring; and more particularly when the cold is applied partially. Many persons have a common cold in a few minutes, if exposed to a draught; but they will bear exposure to the air without any such effect. Mere cold will cause it, without any subsequent application; because, while sitting in a room without a fire, when we ought to have one, the nose will begin to "run," before we go into a room with a fire. While we remain in the cold room, we begin to sneeze; and other symptoms of catarrh come on;—proving the action of the cold itself. Most probably the constriction of the skin being so great, the Schneiderian membrane passes into great activity. Change of residence appears to increase the susceptibility to the disease. Some susceptible people always take cold if they change their residence; and some will catch cold without leaving their beds.

*Treatment.*—The best mode of treatment, is to keep the body perfectly warm;—so as to get rid of the chilliness. It is usual to increase perspiration by wine and brandy, and other stimuli; but it is better to do it by caloric itself. The warm-bath, or a vapour-bath, is very good; and a local bath is also very proper; and when the patient is warm, plenty of hot liquids, without any wine or brandy, are exceedingly useful. If we put wine and brandy into hot liquors, there will most likely be headache afterwards.

*Diet and Exercise.*—During this time a person loses his appetite; and therefore nature indicates that he should take but little food; and that little should be chiefly fluids, and of a weak nature. When a person has been ill for any length of time, one of the best modes of getting rid of the cold, is by perspiring through exercise. Exercise in the open air if possible; or good exercise, at any rate,—so as to produce considerable perspiration,—is one of the best remedies. But great care must be taken not to catch cold, when perspiration is induced; for if a person allow himself to cool suddenly, when he is hot, his last state will be worse than his first. Good brisk walking, or dumb bells, or battledore and shuttlecock, or skipping, are highly serviceable. The patient should be careful to keep himself warm afterwards; or he will catch cold upon cold, till the most serious effects are produced.

*Influenza.*—Catarrh is sometimes epidemic; and then it goes by the name of "influenza."<sup>b</sup> We have numerous returns of this epidemic catarrh throughout Europe; and it is not confined to the human race; for horses, dogs, and cats are all liable to it. There was a very remarkable influenza in England, in the year 1782;—there having been one in the East Indies and China, in 1780. It appeared (as many epidemics do) to travel westward;—having made its first appearance in the east. Respecting that epidemic, it is mentioned that an East Indianman (the *Atlas*) had its crew attacked, while sailing from Malacca to Canton; and when it arrived at the latter place, they found that the people had all had influenza there, about the same time that the crew had had it at sea. This was an argument against the disease being contagious; for if the people had it out at sea, and found, when they arrived at a distant part, that the inhabitants had had it about the same time, it shows that it must have been something atmospherical, and not any thing communicated from man to man. There has been a great difference of opinion respecting the contagiousness of different epidemics of this kind. Some contend that this and that influenza is merely epidemic; and others, that it is epidemic through its contagious nature. We have had epidemics of this description, but I never saw

<sup>a</sup> See Page 730.

<sup>b</sup> The Italian word for "influence."

any thing to make me believe that the disease was contagious; though I should be sorry to deny it merely because the cases that came under my notice, did not appear to be contagious. Strong facts have been adduced to show that it is contagious; and then there are others, equally strong, tending to show the contrary;—just as is the case with regard to cholera.

The symptoms are usually more severe than in common catarrh. When the disease is epidemic, it is not so slight as when sporadic. When epidemic, there is generally complete loss of appetite, great lassitude and debility, and a very severe cough. It will attack persons both *out of doors* and *in doors* indiscriminately; and also individuals at sea. Sometimes it affects every member of a family at once; and sometimes it affects them in succession.

The epidemic influenza attacks people of all ages; but children less than others. It is sometimes fatal to persons who have chronic disease of the chest. An influenza is sufficient to stir up inflammation, when it exists in any part of the body. When the disease is not epidemic, but sporadic, it lasts from a few days to a few weeks; and when it is strictly epidemic, it generally continues for a few months. What the cause of it is, I do not know.

## SECTION VI.—SPASMODIC AFFECTIONS OF THE LARYNX.

[Endowed with a curious and complicated muscular apparatus, and with exquisite sensibility, the larynx is liable to various forms of neurosis. Of these, the active have only, as yet, been investigated; while of the existence of the passive forms scarcely any notice has been taken. Under the first head we may class the spasmodic croup of children, the spasm of the glottis in hooping-cough, and the various forms of hysterical, nervous, and sympathetic cough; while of the second we can only say, that paralysis of the muscles of phonation is seen in certain cases of cerebral disease; and that, reasoning from analogy, we may further admit the existence of another form of paralysis, similar to that of the intestines in ileus, and of the intercostal muscles in pleurisy, and resulting from the same cause;—namely, the inflammation of a tissue in connection with the muscular fibre.<sup>a</sup>]

### *a. Laryngismus Stridulus.*

*Resembles Croup.*—[There is a disease which often attacks the larynx, especially that of infants and children; which has so near a resemblance to croup, as to be very generally confounded with it; and which is hence known by the name of “spasmodic croup.” But notwithstanding the resemblance of many of its symptoms, it is essentially different from it, and ought to be arranged in a different place. The distinctive characters of bronchlemlitis or croup are, inflammation of the mucous membrane of the trachea and bronchial vessels; and the secretion of a peculiar concrete and membrane-like material, that lines the tracheal tubes, and threatens suffocation by obstructing them. In the disease before us, we have neither inflammation nor membrane-like secretion; while the sense of suffocation is produced, not by obstruction, but by spasm.

*Distinguished from Asthma.*—Nor is it strictly an asthma; though it makes an approach to it, and forms the “*Spasmodic Asthmas*” of Millar, Parr, and various other writers. In asthma, the constriction commences in the chest, and chiefly exerts itself there; though the spasm may extend to the upper part of the trachea. In spasmodic laryngismus, the constriction commences in the larynx, and is chiefly confined to that organ; though it may extend to the chest. In the former, the respiration is wheezy, but the voice is not stridulous; in the latter, the voice is stridulous, but the respiration is rarely wheezy, or rather rarely so in an equal degree;—evidently showing a difference in the seat of the two diseases.<sup>b</sup>]

<sup>a</sup> Stokes on Diseases of the Chest; Part 3; Section 1; Page 261.

<sup>b</sup> Dr. Mason Good's “Study of Medicine,” Class 2; Order 2; Genus 2.

*History and Progress.*—[This convulsive affection occurs by paroxysms, with longer or shorter duration in different cases, and in the same case at different times. It consists in a peculiar mode of inspiration, which it is difficult accurately to describe. The child, having had no apparent warning, is suddenly seized with a spasmodic inspiration; consisting of distinct attempts to fill the chest, between each of which a squeaking noise is often made; the eyes stare, and the child is evidently in great distress; the face and extremities, if the paroxysm continues long, become purple; the head is thrown backwards, and the spine is often bent, as in opisthotonos: at length, a strong expiration takes place; a fit of crying generally succeeds; and the child, evidently much exhausted, often falls asleep. In one of these attacks a child sometimes, but not frequently, dies. They usually occur many times in the course of the day; and are often brought on by straining, by exercise, and by fretting; and sometimes they come on from no apparent cause. They very commonly take place after a full meal, and they often occur immediately upon waking from sleep; though, before the time of waking, the child had been lying in a most tranquil state. As the breathing is affected by these paroxysms, the complaint is generally referred to the organs of respiration, and it has been sometimes called "chronic croup;" but it is very different from croup, and is altogether of a convulsive character;—arising from the same causes, and relieved by the same remedies, as other convulsive affections. Accompanying these symptoms, a bending of the toes downwards, clenching of the fists, and the insertion of the thumbs into the palm of the hands, and bending the fingers upon them, is sometimes found, not only during the paroxysms, but at other times. Clenching the fist with the thumb inserted into the palm of the hand, often exists for a long time in children without being much observed; yet it is always to be considered as an unfavourable symptom, and frequently is a forerunner of convulsive disorders;—being itself a spasmodic affection. It rarely happens that a child recovers from an attack of this sort, unless the progress of the disorder has been interrupted by a timely application of proper remedies, without a general convulsion. Then the friends become alarmed; and a disease which had existed for two or three months, is, for the first time, considered to be important enough to require medical assistance; after all the farrago of popular medicines—such as "fit-drops," "soot-drops," assafoetida, &c.—have been ineffectually applied. Convulsions of this description seldom, if ever, occur after the expiration of the third year of a child's life; and not often in children which have lived by sucking till they have teeth, and have never taken animal food till the "dentes cuspidati" have come through the gums; this, however, is liable to some exceptions.<sup>a</sup>]

*Causes.*—[The principal causes of the croupy convulsion in children, in a practical point of view, are:—1. *Dental Irritation.* 2. *Gastric Irritation.* 3. *Intestinal Irritation.* And here I<sup>b</sup> must make the all-important practical remark;—that I have never seen the measures suggested by this view of the causes, when *early and effectually* enforced, fail in remedying this disease. Besides these especial causes, there are others which act upon the nervous centres. Passion, vexation, and certain odours, are of this class; and (singular as it may appear) the state of sleep *predisposes*, at least, to attacks of this kind of convulsion.

*Pathology.*—The origin of this disease was erroneously referred to the cerebrum by the late Dr. J. Clarke, to whom we owe its detection; and to compression and consequent paralysis of the pneumogastric and its recurrent nerves, by the late Dr. Hugh Ley, to whom we are indebted for an otherwise invaluable treatise upon it.<sup>c</sup> It is, in reality, an excitation of the true spinal or excito-motory system. It originates in:—1. The *Trifacial*, in teething. 2. The *Pneumogastric*, in over or improperly-fed infants. 3. The *Spinal Nerves*, in constipation, intestinal disorder, or catarrhis. These act through the medium of the *Spinal Marrow*, and:—

<sup>a</sup> Dr. John Clarke's "Commentaries on the Diseases of Children."

<sup>b</sup> Dr. Marshall Hall.

<sup>c</sup> "An Essay on the Laryngismus Stridulus, or Croup-like Inspiration of Infants. By Hugh Ley, M. D."

1. The *Inferior* or *Recurrent Laryngeal*, the constrictor of the larynx. 2. The *Intercostals* and *Diaphragmatic*, the motors of respiration. When the *crowing inspiration* passes into actual *convulsion*, the larynx, from being *partially*, becomes *perfectly* closed; and there are violent *expiratory* efforts, with consequent congestion of the encephalon, and all its terrific train of evils. The same mode of viewing this important subject, leads us to give its proper place to *each* of the series of symptoms: the *spasmodic* or *spinal* are the *first* in order; the *cerebral* the *second*. We are thus enabled to see the just relation and position of effusion into the ventricles of the brain, with regard to this disease; it is the *effect*, not the *cause*.

*Treatment.*—The proper mode of treatment comprises the remedies—1. *Against the attacks.* 2. *In the attacks*, and in the *threatening* of the attack. 3. *Against their effects.* The remedies *against* the attacks, or the *prevention*, consists in avoiding all the exciting causes: dental, gastric, or intestinal irritation; passion; vexation; disturbance; interrupted sleep; &c. The remedies in the *threatening* of attacks, consist in the watchful and prompt repetition of the same treatment, lancing the gums, and relieving the stomach and bowels. The *sleep* especially should be watched; and if there be a sardonic smile, or starting, or other symptoms, the little patient must be *gently* awakened; and the remedies just enumerated should be administered. Mental agitation must be most cautiously avoided. After the gum-lancet, I would advise a copious enema of warm water. If there be great threatening of an attack, I would tickle the fauces, dash cold water on the face, and irritate the nostrils;—having the patient placed, as speedily as may be, in the warm-bath. To guard against the effects of the attacks, we deplete the blood-vessels about the head with cupping, or leeches; apply an alcoholic lotion constantly all over the head; or, if the case be urgent, the ice-cap. In addition to these measures, the secretions must be corrected;—mild mercurials being given, perhaps, to affect the system; and diuretics, if the urine be scanty: afterwards, change of air is of undoubted efficacy; and a very mild tonic plan may be added with advantage;—as minute doses of the sulphate of quina, of the carbonate of iron, &c. Sponging with *warm* salt-and-water, is also a valuable auxiliary remedy. It is impossible to conceive the vast importance of this subject. If any thing could add to this importance, it is the fact that the convulsions of infancy frequently lay the foundation of epileptic attacks in youth, or adult age. Sometimes the transition is so gradual and continuous, that the two affections are proved to be obviously the same.

With the same objects, the diet and the condition of the bowels must be attended to with *equal* energy. *All* irritation must be avoided; and, among these, *drastic* medicines must be ranged. A young nurse's or ass's milk should constitute the diet. Enemata of warm water may be used, effectually to relieve the bowels, night and morning. The "tinctura hyoseyami" and hydrocyanic acid are important auxiliaries; but especially change of air. A cold lotion, the ice-cap, and perhaps leeches, must be used to guard the head; the feet must be fomented and kept carefully warm.<sup>a</sup>

#### *b. Nervous Affections of the Larynx in the Adult.*

[We meet with spasm of the glottis in the adult, either with or without organic disease of the larynx; though in most cases it supervenes on chronic laryngeal affections. In females, however, we find it as one of the symptoms of the protean hysteria; when it may be a transient or long-continued affection. The spasm is commonly during inspiration.

I<sup>b</sup> have not materials to enable me to enter into an account of the various hysterical and nervous affections of the larynx in females; but shall merely enumerate those which I<sup>b</sup> have observed, most of which have been long known:—1. Simple aphonia, supervening on mental excitement. Its duration is exceedingly various,

<sup>a</sup> Dr. Marshall Hall, on Diseases and Derangements of the Nervous System; Chapter 5; Pages 171, 172, 173, 181, and 182.

<sup>b</sup> Dr. Stokes.

and its disappearance often as sudden as its invasion. 2. Fits of croupy breathing. 3. Long continued stridulous breathing, without fever. 4. A hard, loud, solitary cough, without any stridor. In its more violent forms, this has got the name of "tussis ferina." 5. A similar cough, followed by an inspiration not stridulous; but with the *expiration* long, sonorous, and groaning; so as to resemble the howling of a dog. 6. A short but teasing cough, occurring in the most rapid succession; and during the paroxysm causing the greatest distress and exhaustion. 7. The most violent form of the "tussis ferina;" with greatly increased action of the heart and arteries, hurried breathing, loud puerile respiration, and profuse sweatings. In such a case I<sup>a</sup> have seen the disease continue for more than a year; yet there was no emaciation.

Other forms may also occur; but the above are those which have fallen under my<sup>a</sup> own observation. With respect to diagnosis, the points of importance are,—the coexistence of other hysterical phenomena, or their having preceded the symptoms; the absence of fever, the character of the cough; *the want of the regular succession of phenomena as observed in laryngitis*; the frequent absence of hoarseness; and, lastly, the resistance of the symptoms to ordinary antiphlogistic treatment.<sup>b]</sup>

*Spasmodic Cough.*—There is a cough, which occurs every now and then; and which is not the "hooping-cough;" but what may be termed "*spasmodic cough*." This affection is, perhaps, united with a degree of inflammation; or perhaps not; but if it be united with inflammation, it is out of all proportion to it. I believe this is what is meant by "spasmodic cough." I have seen a few instances of a most violent cough, tearing persons in pieces, like hooping-cough; but still it was *not* hooping-cough; and it occurred in adults.

In this disease, iron is by far the best remedy. I have cured every case which I have seen of it, by the exhibition of the sesquioxide of iron. In many of these cases there is no indication for bleeding; although, if the patient be robust, it may be expedient to bleed in the first instance; but I have always treated such cases with the sesquioxide, and with great success. In every case where the cough is out of proportion to the inflammation, or where there is an organic disease (even consumption), iron appears to be the best remedy. Many cases attended by cough and expectoration, which have been mistaken for phthisis, have given way to this remedy.

*Nervous Cough.*—I have now and then seen a very extraordinary cough in young women. All very extraordinary cases, independent of organic disease, are to be seen in young women. Cases are continually seen in young women, of so extraordinary a nature, that we could not believe in their accuracy, if we merely read them in books. I recollect very well seeing a young lady, single,—for these cases almost all occur in single ladies,—who complained, that every time she inspired, she coughed, night and day. She breathed slowly; but when the time came for expiration, she coughed. Nothing was expectorated; and on-listening to the chest, there was nothing preternatural to be heard. She had coughed in that way for months. At first the cough was quiet when she slept; but when I saw her, it would not allow her to sleep. I did her no good; and what became of her I did not hear. It was the most extraordinary case I ever saw. I have no doubt it was a nervous cough;—that it did not depend upon any inflammatory or organic disease; and that it would cease entirely of itself, in the most sudden manner.

*Barking Cough.*—Occasionally females will have a *barking* cough. Sometimes they will have a violent spasmodic cough, such as I have now described, only modified in various ways; so that they will make all sorts of strange noises (such as shrieking);—unattended by organic disease, and apparently arising from a mere nervous derangement of the parts. The exact nature of these affections I have not been able to ascertain.

<sup>a</sup> Dr. Stokes.

<sup>b</sup> Dr. Stokes, on Diseases of the Chest; Part 1; Section 3; Pages 263 and 264.

*Aphonia*.—It is right to mention, that the voice is sometimes lost, or reduced to a mere whisper,—without any inflammation,—without any œdema,—without any obstruction, as it would appear, of the parts. This affection, which is called “aphonia,” occurs chiefly in females; and is altogether what we call “a nervous complaint.” It occurs sometimes in boys as well as in girls; but it is chiefly an affection of women. I think it is easily made out. There is no tenderness of the larynx on pressure; there are other nervous symptoms in the body; and the person is weak and nervous altogether. Frequently there is no tenderness on pressure, and frequently no cough; or if there be cough, there is nothing else;—no pain with it;—no expectoration; and the disease frequently comes on suddenly, and goes off in the same manner. It has frequently come on in the course of a few minutes;—at any rate, in a day. It ceases, perhaps, as suddenly; and then comes on again.

There is no danger whatever; but sometimes persons lose their voice for many months; and I have heard of cases where they have lost it for years; and, from a sudden circumstance, without any apparent reason, the voice will return. I do not know any mode of treatment better than the shower-bath; and attention to the improvement of the general health, in every possible way.

---

## CHAPTER V.

### BRONCHITIS.

#### SECTION I.—ACUTE BRONCHITIS.

WHEN inflammation attacks the air-passages at large, and particularly those within the chest (the ramifications of the bronchia), and affects these latter very severely, the disease is termed “bronchitis” (from *βρογχος*, and *itis*);—inflammation of the bronchia.

*Synonymes*.—This is the most common kind of inflammation of the lungs. The far greater number of those who have what is called “inflammation of the lungs,” have inflammation of the ramifications of the bronchi; so that there is nothing heard of now but “bronchitis;” whereas we formerly used to hear only of “pneumonia,” or “peripneumonia.” But since it has been ascertained that the inflammation which we every day see, resides in the mucous membrane of the bronchia, the term “inflammation of the lungs” has fallen into less frequent use; and we have, instead, the term “bronchitis.” One portion of the substance of the lungs is made up of the bronchial tubes, and therefore the term “inflammation of the substance of the lungs” is very proper; because those tubes are an integral part of the lungs.

*General Symptoms*.—In this affection, which occurs every day, the breathing is quick and shallow. To make up for the shallowness, the patient breathes quickly. If the patient breathe deeply, the mucous membrane is put upon the stretch so much, that it occasions great uneasiness. He is more comfortable when he takes a small quantity of air into the chest; but it must be accomplished more frequently than on ordinary occasions. There is frequently a sense of constriction of the chest, and of soreness about the larger bronchia. It is sometimes difficult for a patient to lie down; but in other cases he can do perfectly well. There is every variation as to cough. In some persons there is intense cough; if they even turn a little in bed, it shakes the bronchial membrane sufficiently to produce cough. Some cannot turn; some can scarcely lift their arms;—they cannot produce so slight a motion of the chest as that, without experiencing cough. In other patients the cough is by no means severe. If it be severe, people are confined to their bed; but if not, the motion produced by exercise makes the breathing more difficult.

*The Expectoration.*—From the first there is some expectoration. The mucous membrane cannot be so irritated, without secreting more than it should; and this expectoration may increase to a very great amount. If the inflammation become very severe, it diminishes again;—but still the patient has more secretion than in health. If a person have a very active inflammation, the secretion diminishes; and then, when the disease declines, or degenerates into the passive or atonic form, the secretion may become immense. At first it is thin; but it soon becomes thick, and frequently of a very yellow colour,—so as to look almost like pus; only it is very glutinous; and, for the most part, swims in water. It may appear very black;—as black as if soot had been mixed with it; but there are various other shades;—blue, green, yellow, and white. This expectoration is not excessively tenacious. It is certainly viscid; but not so tenacious as when the air-cells are inflamed. In the latter case, the matter is so tenacious, that if a person spit into a vessel and turn it up, the expectorated matter will not run out, but will adhere to the sides.

*Headache.*—There is headache, sometimes very severe, when the cough takes place. The headache is of that character, when it exists at all, that patients almost always describe it as “a *splitting* headache;” and sometimes there is drowsiness. There is great congestion in the head; and a more or less inflammatory state.

*The Pulse.*—The pulse is accelerated. It may be as high as 100; or even still higher. As the inflammation affects a mucous membrane, the pulse is generally large and soft. It may be hard;—for there is a great variety in these things, but for the most part it is full, and rather soft; or, at any rate, not a *firm* pulse. There is not the softness of *debility*; but a pulse of no remarkable *power*.

*State of the General Surface.*—The skin is frequently dry; and, of course, the tongue is dry, and generally of a dirtyish white colour; and sometimes it is covered with a great deal of mucus. The skin, for the most part, is hot; and now and then persons sweat violently. The face, too, shows great congestion. General congestion probably takes place; for, in many cases, there is drowsiness and headache; and there is likewise redness and fulness of the face. At the moment of coughing, the veins of the temples and neck are greatly distended, and the whole face becomes turgid.

*Progress of the Disease.*—If the disease go from bad to worse, the patient cannot lie down at all. His face becomes livid, from the congestion. The lips become purple; and I have seen the face become really black;—of such a hue that I could not have believed it had been the result of bronchitis, if I had had it represented to me. It was as dark as when a patient has taken nitrate of silver to a great amount; or where there has been a communication between the two ventricles of the heart. The pulse, at last, becomes weaker and softer; and, at the very last, vermicular. The surface becomes blue; and both the forehead and chin are bedewed with a cold clammy perspiration. In this state of things, the expectoration becomes very scanty, or ceases altogether; not because it is not secreted, but because the patient is too weak to expectorate it; so that he may almost be said to be drowned inwardly by mucus. In cases which are left to themselves, or badly treated, it is said that dyspnœa comes on about the fifth or sixth day, and is followed by death.

If, on the other hand, improvement take place, the constriction is removed. The cough is not much diminished; but it does not hurt the patient as it did. There is copious expectoration. The pulse becomes slower and softer; without, however, becoming so soft as in health. The surface perspires; and the tongue becomes moist. Still, if the case be severe, there is a discharge which appears to be puriform. In other cases, the patient neither gets well nor dies; and then there is considerable expectoration. Still the pulse is kept up, and still it is hard. In consequence of the cough, he does not gain strength; but perhaps becomes more and more emaciated. He has night-sweats; and at the end of many months he may die, or get all but well; and then when he is exposed to a common cold, he may have difficulty of breathing, and more or less bronchitis; so that some persons who have been ill, will

never be able to get through a winter without an attack of asthma;—that is, shortness of breathing.

*Signs afforded by Auscultation.*—Besides these symptoms, however, there are others which may be learned by the ear. As bronchitis is an inflammation of the inner surface of those tubes through which the air passes, they are necessarily altered in diameter; and instead of being only moistened, there is an *abundance* of mucus, and mucus of a different consistence to what it usually is; we must therefore suppose that there will be a very different sound in this disease, from what there is in health. On listening over the part that is inflamed, we hear, instead of the natural murmur, a sound both louder and rougher than usual; and if the inflammation be very great, the sound is then so loud and rough, as to resemble the *snoring* of some small animal. This is called the noise of “*sonorous* respiration,” or “*sonorous rattle*.” Some choose to use the Latin word “*rhonchus*,”<sup>a</sup> and some say “*râle*,” and would not say “*rattle*” for the world, because it is not scientific. However, there is a rough snoring sound: something like the bass string of an instrument. Besides that, we frequently observe a squeaking or shrill sound;—something like the chirping of a bird; and that is termed “*sibilous* rattle.” It is frequently shrill, like the noise made by a grasshopper. One or both of these phenomena we constantly observe. Of course they are not heard all over the chest; but only at those parts where the tubes are affected.

There is another peculiar circumstance in this affection; namely, that all at once, while we are listening, the sound occasionally ceases entirely; and if we continue to listen, we hear it again as before; or if we make the person cough, we then hear the sound of respiration again. This is peculiar to the disease; and arises, as is supposed, from a large tube becoming temporarily obstructed by mucus;—so that its ramifications get no air; and, when the mucus is removed, the air enters as before. When the sound of respiration ceases in a part, if we only make the patient cough, that is generally sufficient to dislodge the mucus, and the respiration returns. This is called, by Laennec, a pathognomonic sign of this disease.

Sometimes, on placing our hand over the chest, we discover a vibration at the same moment; but that is not always the case. It depends upon the extent, or the intensity of the affection. If the air pass with great difficulty, it shakes that portion of the chest. However, it is not of very great importance.

*Auscultation of the Cough.*—This *wheezing* (as we call these rattles in English) occurs, not only when the person is *speaking*, but in a much more marked degree when he is *coughing*. If we have a doubt about the nature of the disease,—as to whether it is bronchitis or not,—because we do not hear a sonorous or sibilous rattle, by making the patient cough, we may then determine the nature of the case to a certainty. In coughing, there is generally a more violent inspiration; and as soon as we produce that, it will have the desired effect. Frequently also this disease may be detected at the back and root of the lungs, when we cannot find it any where else. In that situation, both in respiration and in coughing, sonorous and sibilous rattles are frequently heard, when they are heard nowhere else. In most instances, persons can tell a case of bronchitis without this; but sometimes they cannot. Sometimes a patient will breathe quickly, and the pulse will be quick, and yet we are at a loss to say what the disease is. Sometimes I have known it difficult to say whether the disease was in the chest or not; whereas, by listening to the chest, and making the patient breathe quickly and cough, the disease has been fairly made out. In listening to the respiration, in a case where we suppose there is bronchitis, it is right to make the patient breathe as quickly as he can; and we shall then hear the sounds more distinctly; it causes still more full respiration.

If the affected part be at a considerable distance from the front, we cannot hear the rattles well. The nearer they are to the surface, the louder we hear them.

*Signs afforded by Percussion.*—In bronchitis the sound on percussion is not

<sup>a</sup> A snorting, or snoring.

altered; on striking over every part of the chest, we find it sound as in health. At the very moment at which we may cease to hear respiration at one part, if we strike that part, we still hear a hollow sound; and for this reason;—although respiration is not going on, there is air there. There is no fluid collected, and no solidification of the lungs; but the air is there much as it is in health; and therefore, on striking, we have the natural hollow sound.

[Dr. Stokes, in the following propositions, has indicated the present state of our knowledge with respect to the physical diagnosis of simple bronchitis:—

“1. In almost all cases, percussion gives no direct sign. 2. An accumulation of mucus in the lower portions of the lung, may give a certain degree of dullness. 3. In the great majority of cases in which there is a coexistence of the signs and symptoms of bronchitis with dullness, we may infer the existence of some disease, either of the parenchyma or of the pleura. 4. Conversely, the absence of dullness with the existence of irritation of the lung, gives a great probability that the case is one of simple bronchitis. 5. A copious effusion of muco-purulent matter may exist in the bronchial tubes, without a perceptible dullness of sound on percussion. 6. In certain cases of bronchitis with effusion, a metallic sound may be produced on percussion. This is somewhat similar to the *bruit de pot fêlé* of caverns; but is to be distinguished from it by the clearness and greater diffusion of sound, and absence of the stethoscopic signs of a cavity. 7. In many cases, on application of the hand, a distinct vibration is felt, in accordance with the motions of respiration. 8. The modifications of respiration, as observed by the stethoscope in bronchitis, seen to be connected with mechanical obstruction more or less complete, and which may proceed from one or all of the following causes:—turgescence or hypertrophy of the mucous membrane; the existence of various secretions; and, lastly, the occurrence of spasm. 9. In the mode of recurrence of the various phenomena, there are the greatest possible differences in different individuals. 10. As a general rule it may be stated, that the more intense the sonorous, sibilous, or mucous râles, or any combination of them, during ordinary respiration, the more severe may the disease be considered. 11. But in certain cases of intense bronchitis of the minuter tubes, the sounds during ordinary respiration cease to be a measure of the intensity of disease; as they become louder during the convalescence of the patient. 12. In the secretive stage of bronchitis, the mucous rattle may occur, on the one hand, with large and isolated bubbles; and, on the other, may pass into a râle almost crepitating;—the sound on percussion still continuing clear. 13. In consequence of bronchial inflammation, the entrance of air into a certain portion of the lung may be prevented; in which circumstances, the signs are nullity of respiration, with persistence of clearness of sound. 14. This obstruction may result from organic change of the mucous membrane, or from the plugging up of the tubes by their own secretion. 15. In the first of these cases, the absence of diminution of the respiratory murmur is permanent, while in the second it may be temporary, and removable by a fit of coughing; yet, even in this case, the obstruction by concrete mucus has continued from the period of its occurrence, until the fatal termination. 16. If in a case of mucous catarrh, a sudden dyspnœa supervenes, with absence or diminution of the respiratory murmur in a particular portion of the lung,—this portion also preserving its clearness of sound on percussion,—we may make the diagnosis of obstruction of the bronchial tube by its own secretion.”<sup>a</sup>]

*Treatment.*—The treatment of this disease is perfectly easy. We have only to bleed the patient well, and to follow it up by local bleeding. According to some, the latter answers better at the back, than at the front. I do not know that this is the case, but some say they have contrasted the two modes;—which is more than I have done. I have generally been contented with cupping at the front. Some say there is more advantage from cupping on one side of the spine; and others prefer the root of the lungs, and the large vessels. I am quite sure that, in this disease, mercury is of the greatest use. I have had many cases that have yielded

<sup>a</sup> Dr. Stokes, on Diseases of the Chest; Part 1; Section 2; Pages 79 to 81.

the moment the mouth has become sore. Or if we choose, instead of making the mouth sore, great advantage may be derived from the exhibition of tartar emetic in large doses;—so as to keep the patient nauseated, and from time to time produce vomiting. Vomiting causes a great discharge from the affected parts; and therefore it is more useful than in any other inflammation. In many inflammations, it would be dangerous to practise vomiting; but in bronchitis many trust, next to bleeding, to the exhibition of full doses of tartar emetic;—a grain or more every three or four hours. However, I am not so satisfied with this plan, as with making the mouth sore; but if the patient do not go on so fast as we could wish, then we may give tartar emetic afterwards. Nevertheless, I am quite satisfied that making the mouth sore is one of the most expeditious modes of cure. I need not say that blisters, low diet, and moderate purging, are also exceedingly proper. The treatment is that of common inflammation;<sup>a</sup> and if it be well practised in time, and if the patient be not the subject of chronic bronchitis, the treatment is easy enough. If the patient have *acute* supervening on *chronic* disease, our chance is slight; but even then the case must be treated on the same principles.

## SECTION II.—ASTHENIC BRONCHITIS.

*Symptoms.*—It is to be particularly remembered, that bronchitis will sometimes destroy life in the most insidious manner. It may exist without pain, and may then be easily passed over; I mentioned that it will frequently exist with little cough,<sup>b</sup>—not half the cough that is often present in common catarrh;—and then also it may be easily passed over. The patient is considered to have “a little cold;” but there is such prostration of strength, as surprises every body; and in three or four days the individual is past hope. I have known several cases of this description. This occurs particularly in those advanced in life; and therefore, whenever we are consulted by individuals near sixty, or who have passed that age, and we observe difficulty of breathing, the respiration hard, and the pulse quicker than it ought to be, it is well to listen to the chest, and find what disease he has. The respiration may be sonorous, sibilous, or both; or perhaps mucous; and the patient may be labouring under excessive inflammation of the bronchia. We may hear these sounds in many parts of the chest.

*Pathology.*—This species of the affection is called “*asthenic* bronchitis;”—that is, the form of inflammation which is described as *atonic*;<sup>c</sup> where the inflammation, however active, may be attended by no great strength of constitution; and where it very soon degenerates into passive inflammation, or the patient absolutely sinks. There is no power in the *system*; but the *parts themselves* are more or less inflamed: and at that time of life, with such a state of the constitution, the inflammation is sufficient to expend all the powers; and at the end of a few days the patient sinks. When a patient, therefore, in the decline of life, has a cold sufficient to make him call in medical assistance, it is necessary carefully to examine the breathing; and to observe whether it is frequent or not. It is also right to listen all over the chest; in order to ascertain whether there is not a pretty considerable degree of bronchitis;—considerable either in *degree* or *extent*; for sometimes it is inconsiderable in degree, but considerable in extent; and that is quite sufficient to hurry the respiration.

*Treatment.*—This is an unpleasant case to treat; and I have lost many such patients in a winter. They are usually seventy years of age, or older; they have bronchitis; they cannot bear much bleeding; their powers are gone; and it is frequently vain to attempt to relieve them. All we can do is to bleed to two ounces; to bleed locally; to apply blisters; to get the mouth sore; and to give emetics; but we cannot do much with any thing.

*Tonics.*—When the *sonorous* and *sibilous* rattle degenerates into *mucous* rattle;

<sup>a</sup> See Page 118.

<sup>b</sup> See Page 737.

<sup>c</sup> See Pages 111 and 130.

if this be observed all over the chest; if the patient's powers be gone, and he cannot lift himself in bed without aid,—we may occasionally get him through, by good support, by wine and milk, and (according to the practice of some) by bark; but very frequently, in spite of all that can be done, he will slip through our fingers. It is always provoking to lose a patient; but there is sometimes an especial reason for it; and we lose our credit, because we have not alarmed the family, as we should have done. When old people are attacked with this disease in such an insidious manner, and their strength is all gone, it is very easy to offend the family by saying the patient has “only a cold,” when he is all but dead. I have heard some old practitioners say, that these cases should be treated with bark and wine from the very first; and that they invariably cure the patient. One always doubts a man who says he cures *every* complaint, however excellent his plan may be. The powers have been prostrated, from time to time, by some cause or other; but after the first bleeding (with which, perhaps, we cannot go far), and after blistering, and producing a slight affection of the mouth, or nausea and vomiting, it is necessary, in a short time, to support the patient well; and if there be any doubt about the propriety of going on with this strengthening plan, it is better to do so;—giving an emetic every day, so as to clear out the chest, and induce a free secretion; and during the rest of the day, giving bark or quina, and good nourishment, or even wine.

*Opiates.*—In these cases it is necessary to procure rest by means of opiates or narcotics, of various descriptions; but the essential thing is to cure the bronchitis. The bronchitis frequently comes on in an insidious manner, and is accompanied by no constitutional signs; but it is in old people that this particularly happens. We never see it in children, or in the middle period of life; but in those advanced in years we see it every day.

*Sometimes called Peripneumonia Notha.*—It is this form of the disease that has been called “peripneumonia notha;”—as if there were *bastard*, not *real*, peripneumonia; but I believe the word is used very indefinitely. Sydenham applies this expression to common bronchitis; where the head is “ready to split,” and where all the symptoms present are such as I described as common to bronchitis.\* We had better abolish the term “*peripneumonia notha*,” and remember that there is a disease of the air-tubes (that is, bronchitis) that may be *active*,—accompanied by strength; and must be cured by strong measures; and that sometimes it is attended by no strength at all; or, at least, that the strength will all go away in a day or two; and that whatever measures are adopted, must be employed the first few days. I believe the term “*peripneumonia notha*” was supposed, by some, to apply to the latter state only; but if we read Sydenham, we shall find it clear that he applies the term to those cases where there is considerable pain.

### SECTION III.—CHRONIC BRONCHITIS.

Bronchitis is very frequently a *chronic* disease. Sometimes, and indeed generally, this is a mere degeneration of the acute form. In some persons, the disease, when it has once begun, however acute it may be, never ceases. At least, they have it every winter afterwards. Subsequent attacks of the disease may not be *active*, but more or less *passive*; and some patients have the affection for two or three years, and then they die. But if we ask many asthmatic people (as they are called),—that is, persons who have passive bronchitis every winter,—they will say that it came on originally after severe inflammation of the lungs, or a very violent cold.

*Age at which it Occurs.*—It is in the middle aged and the young, that chronic bronchitis is most frequently the consequence of a very acute affection. In *old* people, it generally comes on very slowly; and is the consequence of what is

\* See Pages 737 and 738.

apparently nothing but catarrh;—that is to say, a very slight acute attack of bronchitis, in old persons, degenerates into chronic bronchitis. In old people, too, it comes on very imperceptibly. They will perhaps have a severe cold one winter, and have it for two or three months; and then, the next winter, they will have it still worse; and so they go on, as long as they live;—having it worse and worse every winter.

*Commonly called Asthma.*—This chronic bronchitis passes, vulgarly, under the name of “asthma;” and even among some medical men (especially those educated a long time ago) the term “*asthma*” is applied to bronchitis. Now asthma is, properly speaking, a pectoral difficulty of breathing. I say “*pectoral*,” for the causes of many difficulties of breathing, are situated in the larynx or in the wind-pipe. A spasmodic dyspnoea may be situated altogether in the larynx. Asthma, however, is purely pectoral. A spasmodic difficulty of breathing, such as true asthma, is frequently united with inflammation or congestion of the mucous membrane of the bronchia; that is, with chronic bronchitis; because when the mucous membrane is inflamed, it is commonly thrown into spasm; and unless it be removed, the muscles are also thrown into a state of spasm.

*Humoral Asthma.*—When the two diseases are united, they pass under the name of “humoral asthma;”—that is, spasmodic difficulty of breathing, with a great quantity of fluids in the chest. The “humoral asthma,” mentioned in old writers, is nothing more than what I have now stated.

*Frequently a Cause of Asthma.*—Chronic bronchitis is very frequently the cause of asthma. When a part has been frequently inflamed, it becomes excessively irritable, and at length spasm takes place; so that, when a person has chronic bronchitis, it is worse at one place than another,—it is worse at one *season* than at another; and the patient will be seized, all in a moment, with additional difficulty of breathing. We may sometimes have spasm without any inflammation of the bronchial tubes; but a common cause of spasmodic difficulty of breathing, is certainly chronic bronchitis.

*Varies in Degree.*—This chronic bronchitis, whether united with a spasmodic condition or not, varies in degree; from great congestion of the bronchial membrane, and of the whole lungs, down to a mere gleet,—a mere flux or gleet of the mucous membrane; in which state the mucous membrane may be red, or it may be without the ordinary signs of inflammation. We may have nothing but a mere gleet;—such as occurs in gonorrhœa when it has long gone by; and which, of course, does not deserve the name of inflammation. It appears to me (as I mentioned formerly<sup>a</sup>) that, in the latter case, there is exactly the same state as we see in a serous membrane, where it pours forth a great quantity of fluid, but where no signs of inflammation can be discovered. On the contrary, the parts are whiter than usual, and have the appearance of satin.

*Symptoms: Cough.*—In all these varieties of chronic bronchitis there is cough. There is also copious expectoration; and the expectoration is of all descriptions;—frothy, ropy, mucous, serous, watery, tenacious, and viscid (like gluten). Sometimes it is short and creamy;—just like pus; and sometimes it is absolutely purulent. These varieties of expectoration frequently exist, at the same time, in different proportions; and sometimes they succeed each other. The expectoration may be sweet and inodorous; or it may be dreadfully fetid; but there is no danger from the latter circumstance. I have seen females with expectoration so fetid, that their sisters could not bear to sleep with them;—so fetid, that they were disagreeable to themselves, and yet no sign of danger whatever presented itself, and the patients did exceedingly well. They were going about without any particular ailment, except that they had a copious expectoration. In colour it will sometimes be bluish, sometimes black; or it may be yellow, green, brown, or reddish. The latter is owing to the admixture of a little blood in it. Then, as to quantity, it may vary from a few ounces to two or three pints, in the twenty-four hours.

<sup>a</sup> See Page 107.

*Dyspnœa.*—The other symptoms vary in intensity. There may be dyspnœa, or there may be none at all. There may be merely cough and expectoration; but that is more particularly the case in what may be called mere “gleet of the mucous membrane.” When there is congestion of the lungs, or a spasmodic constriction, we may have difficulty of breathing; and in other cases there may be such dyspnœa, that the patient cannot lie down;—such dyspnœa, that it will cause plethora of the head, face, and neck, distension of the jugulars, suffusion of the eyes, and (I might almost say) blackness of the nose and lips, or even of the whole face. In such cases of extreme congestion, the extremities may become cold and blue, and the urine scanty. The pulse may be either full, or small and feeble. In short, there may be all those symptoms which make many believe that hydrothorax has existed;—that, unquestionably, there has been water in the chest. It is in cases of this description that we are told, every day, by those who never employ their ears, that such a patient has water in the chest; and yet, on opening them, find none at all, or not sufficient to explain the symptoms. I have frequently seen persons with all these severe symptoms; and yet, on opening the chest, there has not been a drop of water found in it; but I have found the lungs so congested with blood, that they would not collapse. On listening with the ear, all this was clear beforehand. Respiration was heard at the lowest part of the chest; whereas, if water had been there, we could not have heard respiration. On whatever side water exists, if the person be upright, there can be no respiration in the situation of the water; and on striking the part there can be no hollow sound;—on the contrary, the noise produced is like that occasioned by striking a solid, fleshy part,—like the thigh. Chronic bronchitis, therefore, may sometimes exist without any congestion of the lungs; or there may be the greatest degree of congestion.

*Signs afforded by Auscultation.*—This disease is very easily recognized, without auscultation; but the simplicity of the affection can only be determined by the aid of the ear. A person may easily say that another has bronchitis, whether it is acute or chronic; but without the aid of the ear, it is frequently impossible to say whether there is not something worse than bronchitis. Bronchitis may be frequently cured, or so reduced that little may be left; but there may be present another disease of a fatal character; and we may be able to ascertain this only by the ear. In chronic bronchitis the rattles (before described<sup>a</sup>) may exist, in most, or nearly all parts of the chest; and they will be in different parts on different days. The different rattles may occur on different days;—“sonorous” rattle one day, “sibilous” another, and “mucous” a third.<sup>b</sup> The “mucous” rattle is seldom continuous. It generally arises from the presence of a great quantity of mucus; and if patients clear the lungs well, (as they generally do,) once or twice a day, then the rattle ceases. In this, as in the *acute* variety of bronchitis, the respiration may occasionally cease in particular parts. It is by no means so frequently suspended as in the *acute* form of the disease; and some say that it *never* is; but occasionally it is lost; and then, for the most part, we hear it again.

*Mistaken for Phthisis.*—That form of the disease which is characterized by great expectoration, and that of a character nearly resembling pus, which is attended by a little dyspnœa, but by no signs of congestion, and which is followed by emaciation,—so that people waste, and at last become hectic, is continually mistaken for phthisis; while, on the other hand, that form in which there is congestion, is mistaken for hydrothorax. That species, which is so often mistaken for phthisis, and passed by, may (if properly attended to) often be cured. This form, indeed, is better known by the *general* symptoms, than by the *peculiar* symptoms I have just mentioned. It is ascertainable by the ear, and by the absence of other symptoms of phthisis;—just as the congestive form of the disease is known, not only by passive symptoms, but by the absence of signs of hydrothorax, or of disease of the heart, and so on. This form of the disease is known by the absence of pectoriloquy; and by other signs, which I shall hereafter mention.

<sup>a</sup> See Page 739.

<sup>b</sup> See Pages 710 and 711.

*Catarrhus Senilis.*—Various names are given to the affection just described. When it occurs in old people, it is called “*catarrhus senilis*” It is a kind of bronchitis, attended with various degrees of congestion, and frequently none; but attended with gleet, and a great discharge; and occurring in old people. It is nothing more than an ordinary affection of a mucous membrane;—that mucous membrane being the bronchial.

*Dry Catarrh.*<sup>a</sup>—Laennec considers the affection just described to be a peculiar form of chronic bronchitis;—a form more frequently attended with asthmatic complaints than any other. He says, that what is called “asthmatic spasmodic difficulty of breathing,” most frequently arises from a kind of bronchitis in which the secretion is exceedingly viscid; and in which the mucous membrane is thickened and swelled,—particularly in the small branches; so that some of them are nearly blocked up; and in which the secretion is glutinous,—even firmer than pitch; and is disposed to form globules the size of hemp or millet-seeds, semi-transparent, and of a pale gray colour. I have no observations of my own on this subject. I have not been able to verify Laennec’s remark; but as he asserts it, it is worth attending to. Where we find asthma occurring, we ought to suspect that it is not a pure disease, but dependent upon bronchitis; and we ought to ascertain whether the expectoration possesses the characters just enumerated. He says that these globular bodies are seen in the expectorated phlegm; and that occasionally they are less consistent, and grow yellow; and sometimes resemble the vitreous humour of the eye. Such an expectoration is hardly noticed by the patient, in the midst of the common mucus which is secreted from the large branches; and which gives rise to so slight a cough, as not to merit his attention. He says the difficulty of breathing,—the spasmodic ailment, is almost the only thing of which the patient complains.

Here then is a *third* disease, which may be supposed to exist without chronic bronchitis; and which has continually been mistaken. Chronic bronchitis, attended by emaciation, may be mistaken for *phthisis*; where there is great congestion, it may be mistaken for *water in the chest*; but that particular form where there is an exceedingly viscid secretion, with small globular bodies, is (according to Laennec) continually mistaken for pure *asthma*.

*Treatment.*—The treatment of chronic bronchitis is very various under different circumstances. According as the symptoms are inflammatory, and our patient strong, must our treatment approach to that for the acute disease; and according as the patient is weak, and there are signs of *passive* rather than of *active* inflammation, so must we be careful in lowering the strength.

*Cautious Removal of Blood.*—In the latter case, where there are signs of *congestion* rather than of *inflammation*, and the powers of the patient are feeble,—we may very easily conceive the great importance of not taking away a drop more blood than is absolutely necessary. Where we see the face black, the body bloated, and the legs swollen, and only a small quantity of urine is formed, it may be necessary to take away a small quantity of blood;—perhaps a little from the jugular vein; or we may cup the patient between the scapulæ, and on the front of the chest; but the loss of more than a few ounces can seldom be borne.

*Diuretics.*—Diuretics and emetics are of the greatest utility. By diuretics we unload the lungs considerably. There is always a great collection of serous fluid in the air-cells and tubes, and by diuretics we produce a great alleviation to the patient. It is a good practice to combine digitalis and squills. We may give many diuretics together, when we cannot increase any one of them. When we cannot give the patient a large dose of squills without making him sick, we may add digitalis. It is certainly a very common occurrence to be able to give diuretics together, many of which have a tendency to produce sickness, without producing

<sup>a</sup> The expression of “*dry catarrh*” involves a contradiction, if we look to etymology; since the word “*catarrh*” denotes a flux or discharge; but as this phrase has been used by the moderns, I shall employ it (in this place) to designate those inflammations of the bronchia, which are attended with little or no expectoration.—*Laennec, on the Chest; translated by Forbes; Part 1; Book 1; Chapter 1; Section 5.*

more sickness by the combination of the whole, than if we gave only one of them. The efficacy of a diuretic is generally thought to be much increased by giving a small quantity of mercury. This is an old remark; and I believe it is a correct one. It is stated, that diuretics act more powerfully upon the kidneys, if we give a small quantity of mercury with them, than if the latter be omitted.

*Emetics.*—Great relief is derived from the exhibition of emetics; and among the best is ipecacuanha. By giving antimony two or three times every day, we debilitate the patient; and this is not a case for diminishing the strength. We only want to unload the air-tubes; but antimony is a very depressing agent; and if given every day for a fortnight or three weeks, it may produce great irritation of the mucous membrane of the stomach (gastrodynia); and therefore I think ipecacuanha is the best. Patients will bear, not merely fifteen or twenty grains, but thirty; and it is a safe medicine. I am told that if given in large quantities, it comes from the stomach, and produces no more effect than a small one. It is of great use to give an emetic every morning, or every other morning, and thus clear out the bronchia; it is an excellent remedy. When acute bronchitis has lasted a considerable time, and we do not deem it proper to evacuate, emetics may be repeated more freely;—especially in the case of children. When the case is not very severe, a nauseating dose of ipecacuanha, squills, and other things of that description, is very useful. Among the best expectorants are those which excite nausea.

*Do not Purge.*—It is always necessary to attend to the bowels. If we do not, there is still more congestion; but it is very dangerous to purge briskly. In these cases the powers of the patient soon sink; and it is better to trust to emetics and diuretics.

*Blisters and Dry Cupping.*—It is frequently of very great use to blister the chest; but the employment of tartar emetic ointment is rather a severe and cruel mode; and I have not seen that it is any better than an ordinary blister. Some persons are fond of “dry cupping.” There is no loss of blood in that operation; and yet there is a great determination of it from the inner parts.

*Narcotics.*—Besides remedies of this description, it is frequently necessary to employ others of a soothing nature. Among the best is hyoscyamus, or conium; which may be given night and morning. There is no rule for the dose of these; but we may increase them to a much larger quantity than we begin with. I have seldom found stramonium of much use in lessening the cough. It is not to be compared with hyoscyamus, or conium, or opium. Opium is one of the best things; but, in many of these cases, there is a great disposition to heaviness of the head; and opium has the inconvenience of confining the bowels; so that though it is a good medicine in the form of Dover’s powder, yet it is not so good as henlock or henbane.

*Inhalation of different Vapours.*—We may soothe the air passages much, by making the patient inhale different vapours. Patients may inhale the steam of hot water; but one of the best modes is not to let them inhale the steam, but to have a vessel so contrived that the air they breathe comes through hot water. We cannot charge air with a dose of salts; but there are many things which may be taken up by the air, and which may be inspired in this way: we might make a solution of opium, or of extract of conium, and let the patient breathe through it. I have not much experience of it; but I have put hyoscyamus and conium into water, and have made the patients breathe it; and this has afforded great relief. Some persons have used prussic acid; and they say it has been productive of great relief. Chlorine may be introduced in this way; and I have seen it lessen the irritation. Some persons employ iodine; but it is right not to use more than one drop of the saturated solution of iodine. Some patients will bear three or four drops, but some will not bear more than one; and I have known some people who could not bear one drop, put into three quarters of a pint of water. It is right to begin with the smallest quantity; and never to increase it beyond what is borne without the least irritation. I had a patient in St. Thomas’s Hospital, who laboured under chronic bronchitis; and who found great relief from breathing through tanner’s liquid.

Without taking any medicine, the tanner's liquid diminished his cough, and he became much better. People living in the neighbourhood of tanners' pits, often find their respiration improved.

*Tonics.*—Where there is no fulness of the chest, but the bronchitis resembles phthisis;—where the patient wastes away, and has a tiresome cough, tonics are of great advantage. Where there is a disposition to dropsy, emetics and diuretics are proper; but where the patient is more or less hectic, and is spitting up a great quantity,—a state which often occurs in young persons,—tonics are of great use; and iron is one of the best. In the first volume of the “Medico-Chirurgical Transactions,”<sup>a</sup> there is an interesting case of a lady, supposed to be in a consumption; but by means of three grains of sulphate of iron, taken twice a day, she got well. I have had cases of that description without end;—where persons were supposed to be on the verge of phthisis; but where there was nothing but bronchitis. There were no signs of tubercles; but there was irritation of the mucous membrane;—producing constant tickling in the throat.

#### SECTION IV.—EFFECTS OF CHRONIC BRONCHITIS.

##### *a. Dilatation of the Air-Tubes.*

When chronic bronchitis has existed for a length of time, it is very common for something more than congestion, and a thickening of the mucous membrane, to take place; it is very common for the bronchial tubes to become *dilated*. Sometimes one, sometimes several branches, and occasionally the whole of the branches in one lung, will become so large, that those which naturally should admit only a fine probe, will have a canal equal to that of a common goose-quill, or even sufficient to admit a finger; and perhaps these dilated branches are seen spreading to others, not nearly so large as themselves. This is the consequence, in some instances, of chronic bronchitis; but whether it is that the particular tubes become hypertrophied, so as to grow to this diameter,—*grow*, in every sense of the word; or whether they become so distended with mucus, that they acquire this increased cavity, I cannot say. It is, however, by no means an uncommon occurrence.

*Varieties.*—There are two or three varieties of this dilatation. Sometimes we see it throughout the tube; and it may occur in one tube or several; and, not unfrequently, the coats of the tube are hypertrophied and indurated at the same time. Secondly, the tubes are sometimes only enlarged in one spot; and then a mere cavity exists. It is occasionally so large, that it will contain a nut. In a third form, the dilatation will occur at intervals; so that there is a series of small enlargements. The pulmonary texture, on being cut into, appears as if it were swollen with a number of small red tumours; and the whole become filled with a puriform secretion. In this last form, the coats are said to be always thin,—as though the dilatation had arisen merely from mucus; while, in the two first forms that I have mentioned, the coats are generally hypertrophied; and the dilatation appears to be the result of the hypertrophy. Hence it would appear, that this dilatation occurs sometimes from hypertrophy, and sometimes from a mere obstruction by mucus; and the result is that, in two forms of the disease, either the whole length or a part of the tube is dilated;—just as is the case sometimes with the heart; while, in the third form, there is a series like a string of beads; and the coats are exceedingly thin; as though the change of form resulted, not from hypertrophy,—for then the parts would not be thinner,—but from simple distension. In cases of this description some other symptoms arise. The disease is attended with great debility; and the patient is “broken-winded.”

*Auscultatory Signs.*—It may be supposed that such an alteration as this, will give rise to some alteration in the sound of the chest. This is a matter rather of

<sup>a</sup> Page 13. The case is reported by Dr. Stanger.

curiosity and of pathology, than of practical importance; but still, if any disease produce any symptom whatever, it is right to know what that symptom is;—whether it will turn to good account or not. We ought to make it a general rule to go straight forward, and make as accurate a diagnosis as possible, whether we can do good or not; because, if it be not of practical application *to-day*, yet it may become so by-and-by.

When small tubes are dilated, they approach nearer to the natural size of large tubes; and therefore, if there be any difference in the sound of respiration, in the sound of a cough, or in the sound of the voice, in the large branches, it ought to be the same when tubes become large ones;—and this is actually the case.

If it so happen that certain tubes are dilated, we then hear, instead of the respiratory murmur before mentioned,<sup>a</sup> a sound approaching to that of the bronchia, and even approaching to that of the trachea. This is one of the chief signs of the bronchia being dilated. They may, as I have just said, be dilated to such an extent, as to sound very much like the trachea; but, in general, we have only *bronchial* respiration.

If any of the bronchial tubes be very much dilated, so that *small* tubes attain the size of *large* ones, we have over the former just such a sound as we have over the latter in health. Bronchophony occurs at a part where it should not exist; and if the bronchial tube be dilated enormously,—nearly to the size of the trachea, so that it amounts to a cavity,—we have *pectoriloquy*; and pectoriloquy is neither more nor less than the same sound which we always hear, on applying the stethoscope to the larynx. It must be a very extreme dilatation, however, to enable us to hear the voice come through the tube in this way. It is common to have *bronchophony*; but to have *pectoriloquy*, is a rare thing. Indeed, there must be a larger dilatation than I ever met with. Such a dilatation occurs from time to time; but it is so rare that I never met with it. There are drawings of it; and there is no doubt as to the existence of the fact. In dilatation of the bronchial tubes, therefore, there is bronchial respiration and bronchophony; and if the dilatation be very great, there is tracheal respiration, and a tracheal voice. Of course, the nearer the tube is to the surface, the more clear are these sounds.

#### *b. Diminution of the Air-Tubes.*

Chronic bronchitis, however, will sometimes induce the very opposite state. Instead of causing the tubes to become *dilated*, it may cause their coats to become thicker; and the canal will thus be *diminished*.

*From Effused Lymph.*—Sometimes there is lymph effused within; so that the tubes are completely obstructed. When lymph has been effused within, and the tube has been obliterated for the time, it has been called “a bronchial *polypus*.” It is nothing more than the same occurrence that takes place in croup;—that is to say, lymph is effused; only not in a tubular form. I once knew a case of gonorrhœa, which filled the urethra with lymph; which lymph was discharged in a tubular form. Where the bronchia have been obstructed by lymph, it has been an instance of chronic inflammation;—at any rate, not of *acute* inflammation. In old books, it is said, that nobody could imagine what was the matter with the patient; and that then such a mass as this has been spit up. In cases of this kind, it is easy to say what would be the auricular symptoms: at the obstructed part there would be no sound of respiration; and as soon as the lymph was spit up, there would be the murmur again.

*Contraction of the Sides of the Tube.*—But without such a cause of obstruction as this, the tubes are sometimes blocked up. The cavity is obliterated by the sides becoming thickened and contracted; and then, of course, no respiration is heard at the part; and this want of respiratory murmur is permanent. In the case of acute bronchitis, it will cease (from a temporary obstruction of the tube) for a few hours;

<sup>a</sup> See Page 801.

but coughing removes the obstruction, and we hear the sound of respiration again; but when the obstruction arises from a contraction of the tubes, the want of respiration is permanent.

### *c. Dilatation of the Air-Cells.*

*Improperly termed Emphysema.*—Chronic bronchitis produces a farther change, precisely of the nature of dilatation, of which I have already spoken. The minute tubes of the bronchia terminate in the air-cells; and it occasionally happens that the air-cells are dilated by this disease. This has been called "*emphysema* of the lungs;" but I think it an improper expression; because by "*emphysema*" we mean the presence of air in the cellular membrane, where there ought to be no air. Now in this case there is no air in the cellular membrane,—no air in any place but where it ought to be; only the part which contains the air is too large,—contains too much.

*Appearance of the Cells.*—These dilated air-cells attain, in general, only the size of millet-seeds; but here and there one may be seen the size of a hemp-seed, and even as large as a cherry-stone. When they are the size of cherry-stones, it is very probable that many cells are dilated into one common cavity. I should think this was the cause. At the termination of each twig of the bronchia, where it is as fine as a hair, the air-cells are situated all along it,—just like grapes upon a stalk; I think it probable, therefore, that when a bronchial twig is dilated to a great size, the air-cells which separate from it, are dilated into one. Occasionally, those of the greatest magnitude actually project on the surface of the lung; and are so prominent as to present a large globular form externally. Sometimes they are as large as a walnut, and even larger. There is a preparation at St. Thomas's Hospital, where there is a tumour of this description on the surface of the lung. In extreme cases of this kind, the edges of the lung are quite translucent, and standing away from the body of the lung.

*Occasionally attended by Emphysema.*—If the quantity of air be very considerable, the sides of the cells may crack; and then a communication is established between them and the cellular membrane; so that true emphysema is superadded. In that case, the tumour upon the surface of the lung may attain a very great size; and the air may, by pressure, be forced about. But notwithstanding that the cells occasionally crack, and that air escapes into the cellular membrane of the lung, still it is found, that it does not move about very extensively;—not so extensively as it does in other parts of the body.

*General Appearance of the Lung.*—If lungs with dilated air-cells be inflated and then dried, (which, I imagine, is the best way of preserving them,) the dilatation of particular air-cells will be seen, on cutting into them, to be more considerable than appeared externally. When the dilatation is considerable, and at the same time so extensive as to occupy the whole lung, we find, on opening the chest, that instead of collapsing, the lung rebounds, and projects beyond the chest. A lung thus affected, necessarily sinks less in water than a healthy lung; and, on being handled, does not crepitate in the usual way, but gives such a sound as would arise from the slow escape of air; and we cannot empty it so readily as a healthy lung. The tissue of the lung is drier than in health; and even the roots of the lungs have not the usual infiltration found in that part. The lungs resemble those of a reptile, more than those of a man. The lung of a frog has a large receptacle for air,—not the minute cells that we have; and on opening the animal, the lung escapes the boundary of the chest. When only one lung is thus affected, it has been seen to become so much more bulky than the other, as to push aside the mediastinum, if on the *left* side, and to produce an enlargement of the heart, if on the *right* side.

*Best described by Laennec.*—Laennec has described this condition of the lungs far more accurately, and far more minutely, than any of his predecessors; but (as may be seen from his engravings) it was well known to Dr. Baillie. Dr. Baillie

speaks of an enlargement of the air-cells, causing the lungs to resemble those of amphibious animals.<sup>a</sup> He considers it probable that two or three cells may be broken into one;<sup>a</sup> and therefore, although Laennec has the credit of having first described it, it is right that we should give Dr. Baillie his due. Dr. Baillie also remarks, that Sir John Floyer distinctly describes the disease, as seen by him in a mare; and he considers the remark as applicable to the human subject. "The bladders," says Sir John Floyer, "are either broken, and admit the air into the membranous interstices, or else they are over-distended; like a hernia in the peritonæum. This will produce an inflation of the whole substance of the lungs; and that a continual compression of the air and blood-vessels, which will produce a constant asthma." He was aware of this dilated condition of the air-cells; and he describes asthma as occasionally caused by this over-distension.

*Causes.*—The causes of this over-distension, and rupture of the coats of the air-cells, may be a violent inspiration and retention of the breath;—such as occurs in blowing a wind-instrument. It may be from a mere debility of structure,—a loss of elasticity; but the most common cause is the want of a due expansion of the lungs. Whatever prevents any one part of the lungs from expanding, when the thorax expands;—whether it be a material obstruction of the bronchial ramifications; or a compression of them; or whatever else;—it will occasion those parts which remain dilatable, to keep dilated in a corresponding increased degree, in order to fill up the vacuum which the expansion of the chest occasions. When we inspire, we dilate the chest; and the air rushes down the trachea, and the lungs follow the dilated portions. If there be any part that will not dilate, then (I presume) other parts are over-dilated, to fill up the vacuum; and, in that way, those parts which we distend are *over-distended*, in order to compensate for the want of distension in other parts; and when once over-distended, they are often unable to recover themselves; just as is the case in other parts of the body;—the urinary bladder, for instance. I presume it is on this account, that dilatation of the air-cells is so common in persons labouring under chronic bronchitis;—especially where the membrane is most thickened; and where the secretion, if there be any, is tough and adherent, so as to produce obstruction. Such, at least, is the explanation which presents itself to my mind.

Laennec, however, gives a different explanation. He supposes that the air which passes through the imperfectly obstructed tubes, in chronic bronchitis, cannot easily escape again; but there it remains, imprisoned in the air-cells, by a mechanism somewhat similar to the mechanism of the valves of an air-gun; and the succeeding inspiration introduces a fresh supply; so that the accumulation is very great. I cannot refute this explanation; but the occurrence of the facts upon which I ground *my* explanation, is indisputable; and Laennec, to prove his opinion right, should have shown that the dilated air-cells are those belonging to the tubes in which obstruction exists. That he has not done; and I conceive they are not those in which there is obstruction.

*Auscultatory Signs.*—The existence of this state of the lungs,—morbid dilatation of the air-cells,—cannot be known without the use of the ear. Dr. Baillie, of course, knew nothing of auscultation. It was not known or practised till after his time. But he says, with great truth,—“When the cells of the lungs are much enlarged in their size, persons have been remarked to be long subject to difficulty of breathing, more especially on motion of the body; but I believe no symptom is at present known, by which this disease may be discriminated from others incident to the chest.”<sup>b</sup> The dyspnœa does not differ from the same symptom in other circumstances. It frequently occurs in paroxysms; and will continue for many years. But the pathognomonic signs are obtained from percussion and auscultation;—not from either alone, but from the union of the two; for if, when the air-cells are greatly dilated, we strike that part of the chest, a sound is heard exactly

<sup>a</sup> “Morbid Anatomy,” Chapter 4; Section 7.

<sup>b</sup> “Morbid Anatomy,” Chapter 4; Section “Symptoms.”

as in health, and perhaps even clearer; for, owing to there being but little pulmonary substance there, we have a sound more hollow than even in health. This is the first thing which we must expect. Then, by listening to respiration at the part, there is very little murmur audible. Instead of a number of minute cells, with air rustling in them, there are only two or three cells largely dilated; and therefore the air cannot rustle as before; so that we hear very little of the respiratory murmur. The air which is there, scarcely leaves the air-cells;—scarcely passes to and fro. The part is not expanded; and the consequence is, that there is very little motion of the air. But it is to be remembered, that we *do* hear *some* respiratory murmur; and this is the distinction between the presence of air in the pleura, and the presence of air in merely dilated air-cells. If air exist in the pleura, there it remains; and we have more sound than usual; but, on listening, there is no respiratory murmur; for the air is in a state of stagnation. In the case of dilated cells, however, there is a little air driven out, and a little drawn back again; and therefore there is a trifling respiratory murmur. In the one case there is none; but in the other there is some.

It is said that when this affection is extensive, there is another pathognomonic sign; the inspiration is made with a crackling sound;—as if the air were entering, and distending lungs which had been dried, and the cells of which had been universally dilated. The lungs are drier in this state than in health; and when the case is very severe, the inspirations are attended with the sound I have just described;—a sound similar to that produced by blowing into a dry bladder. This has been termed by Laennec “dry crepitous rattle, with large bubbles.” It is an odd appellation; but it conveys the idea of dryness, and is therefore a “dry crepitous rattle;” and it gives us the idea of the bursting of bubbles, on the surface of fluid; and therefore Laennec says—“with large bubbles.” These are extreme cases. I never witnessed one of them. If we reflect a moment, there is no difficulty in remembering this. When the tubes are dilated, they approach to the size of the bronchia; and the sound must, therefore, be the same in the former as in the latter; and if the air-cells be dilated, it stands to reason that we cannot have the same minute murmur, that we have when the air is passing into a thousand minute cells. It is also evident that we shall have a clear sound there,—just as in health; because there is air there, as before; and if the dilatation be very considerable, we have a clearer sound than before; because there is little else there but air;—little pulmonary substance.

*Treatment.*—Nothing can be done, either for bronchial tubes or for air-cells that have fallen into this dilated state. The treatment will not vary from that proper for chronic bronchitis. We must treat the case on general principles.

---

## CHAPTER VI.

### PNEUMONIA.

HAVING concluded the subject of inflammation of the air-tubes, I shall now proceed to inflammation of the air-cells. A large number of cases of inflammation of the lungs, are considered to be inflammation of the *substance* of that organ; but they are in fact nothing more than bronchitis. In by far the greater number of instances, it is not inflammation either of the air-cells, or of the cellular membrane; but inflammation of the bronchial tubes. Occasionally, however, we have inflammation (as it would appear) of the air-cells themselves. This, properly speaking, is “*peripneumonia*.”<sup>a</sup> The term “*pneumonia*”<sup>b</sup> is the name given to any inflammation

<sup>a</sup> From *περι*, about; and *πνευμων*, the lung.

<sup>b</sup> From *πνευμων*, the lung.

of the heart and pericardium;<sup>a</sup> but the word "*peripneumonia*" is more properly applied to inflammation either of the air-cells, or of the cellular membrane around them;—whichever it may be.<sup>b</sup> For myself, I have no doubt that the inflammation is seated in the air-cells themselves; and it is in this point of view I shall now speak of it.

*General Symptoms.*—The common, well-known symptoms of this disease,—those which are discernible without the aid of the ear,—are very much like those of bronchitis. There is pyrexia, general feverishness, rapidity of respiration, shallowness of respiration, cough, and expectoration. In bronchitis, I mentioned that there is a sense of constriction in the front of the chest; and a soreness (sometimes pretty considerable) in coughing;<sup>c</sup> whereas in peripneumonia, if there be any thing, there is rather a deep-seated dull pain. This is sometimes confined to one spot; though, for the most part, this dull uneasiness is pretty much diffused; and, indeed, is frequently so very slight, that a diagnosis cannot be universally made from it. Then the dyspnœa, if people lie still, is by many persons scarcely complained of, any more than it is in bronchitis. Some persons, labouring under bronchitis, will not allow that they have difficulty of breathing; neither will they in peripneumonia. Just as in bronchitis, there is frequently violent cough; but sometimes there is scarcely any;<sup>c</sup>—the cough is infrequent and soft.

*Character of the Sputa.*—There is, however, according to Laennec, a decided difference with regard to the expectoration. He considers that the expectoration, in peripneumonia, is a pathognomonic distinction; and points out the nature of the disease. He says that when, in this disease, the sputa are received into a flat and open vessel, they unite into so viscid and tenacious a mass, that we may turn the vessel upside down, even when full, without the sputa being detached; for, although they may partially hang from the vessel's mouth, the great bulk still sticks to the vessel. Their tenacity is such, he says, that they vibrate like so much jelly; and the tenacity prevents the air-bubbles from breaking, though they are very numerous in this kind of sputa, and sometimes very large. The air does not escape, but forms bubbles; and for the most part, be they small or large, they remain. I cannot confirm or disprove Laennec's assertion, from my own observations; but I think all will allow that we must look beyond the sputa, as well as beyond the general symptoms, for an accurate diagnosis of this disease. For Laennec allows that the sputa are frequently not so viscid; he allows that, frequently, they are of some shade of red or green; though for the most part they are but little coloured; and he allows that, frequently, they are almost destitute of air-bubbles,—frequently a mass of mere mucus or pituitous secretion, with a few glutinous, and slightly tawny portions. I cannot but think, therefore, as he allows all this, that we ought not at all to depend upon the sputa for a diagnosis. Indeed, when the characteristic sputa do occur, as they continually do, it is very often only at the onset of the disease,—only for a few hours; and sometimes even then only in so small a quantity, as scarcely to admit of being collected.

*Morbid Appearances.*—The pathognomonic signs of this disease, are acquirable by the ear only; but before considering them, it will be necessary to trace the appearances in the lungs after death, and the succession of the changes. This is an opposite course to what we usually adopt. Generally we speak of *post-mortem* appearances *after* we have done with the symptoms; but here it is necessary to reverse the order; for the symptoms are in accordance with the unnatural changes.

*First Stage.*—In the *first* stage of inflammation of the air-cells, the lung merely suffers an accumulation of blood; so that it becomes more solid and heavier than usual. It looks livid externally, and retains the impression of the fingers;—like an œdematous limb. On cutting into it, it is found to be of a deep blood-colour, and replete with frothy, bloody fluid; but still the lung is spongy;—still it crackles under the fingers. This is a stage in which, after death, we find nothing but an

<sup>a</sup> The word is not now used in that sense; and the term "*peripneumonia*" is very much out of fashion.

<sup>b</sup> See Pages 737 and 742.

<sup>c</sup> See Page 737.

accumulation of blood and serum. As the lung crackles after death,—as it contains air to the very last, we expect to hear the murmur of respiration in these particular parts during life; and that is the case; and as air is admitted, we expect to hear, on percussion, the usual hollow sound of the chest; and that likewise is the case. But the murmur which is heard when the inflammation has only reached the first stage, in that particular part, is accompanied (even from the very first moment of the attack) with a crackling sound. We have not the ordinary murmur of respiration; but it takes place with a *crepitous rattle*, as it is called; or, if we please, a *crepitous respiration*. It gives the idea of numerous minute, and almost dry bubbles; and this dry crackling is heard the more decidedly, the nearer the inflammatory spot seems to be to the surface; and those who have employed their ears frequently, can from practice tell the exact depth of the inflammation, from the loudness of the crackling. The nearer the disease is to the surface, the louder is the crackling.

*Second Stage.*—When the inflammation has become more intense (so as to constitute the *second stage*), the lungs are heavy; and they become so firm as to resemble liver; and on this account the term "*hepatization*" has been applied to this state; but, in my opinion, very absurdly. The lungs are not changed into liver. If they were, it would be "*hepatization*;" but if they only remain as *solid* as liver,—something *like* liver, it is an improper word. By "*ossification*," we mean an absolute conversion into *bone*; and by "*hepatization*" we ought to mean a conversion into *liver*. If a thing is to be named in this way, because it is only *like* another, strange words might be applied to every thing. Andral proposes another term,—"*solidification*;" which I think better. If the lungs have become solid, "*solidification*" is a correct term. In this state, where the lung has become solidified, it will not crackle under the finger;—it has evidently become impervious to the air. If we cut it, squeeze it, and scrape it, very little fluid escapes; and what does escape, is not frothy; neither is it so thin as that which escapes in the first stage. I presume that, in these cases, there is more or less fibrin effused or deposited; and that is the explanation of the solidity;—the want of air, and the want of frothy fluid. When the lung has fallen into this condition, we may presume what the symptoms are. On striking that part of the chest where the lung has become solid, of course we cannot have a hollow sound. There is no air there, as there usually is. There is no room for it; but there is a solid mass; and, on striking over it, we have the same dead sound as if we struck over the liver. On listening to the part, as it contains no air, of course there is no respiratory murmur; and, there being no murmur, there is no respiration; so that we cannot hear the *crepitous rattle*. In the *first stage* we have *crepitous rattle*, because there is a thin fluid in the air-cells; but here there is *no* thin fluid in the cells;—they are all solidified; and therefore there is no *crepitous respiration*. If, however, the part happen to be situated near a large bronchial tube, we hear the patient's voice there;—on account of solids being better conductors of sound, than *aëriform* bodies.

*Third Stage.*—Before death, however, a still further change will take place. Inflammation of the lungs tends to suppuration; and, at an advanced period, a *third stage* occurs. But there is a peculiarity in suppuration of the lungs;—the pus is *diffused*, and not collected into an *abscess*. After the second stage, when the third begins, the lung is as hard as before; but it becomes yellowish, or of a straw-colour. When the pus is first formed, in small quantity, there is quite sufficient to change the colour of the lung; but after a little time the pus is more abundant, the lung becomes soft, and will yield to the point of the finger. In this stage, just as in the second, there is no hollow sound on striking the chest; neither is there any respiratory murmur; but a loud mucous rattle;—that rattle which we may have an idea of, by recollecting the sound occasioned by air passing through soap-suds. The mucous rattle is heard in the bronchia; either from some of the pus going into them, or a secretion from their own membranes.

*Abscess of the Lung.*—Should an abscess be formed, however,—should the pus be collected into a mass, a characteristic symptom will be heard; such as I shall mention under the head of "*phthisis*." But such an occurrence is extremely rare.

I do not recollect above twice seeing an abscess in the lungs, great or small, resulting from inflammation; and when I did see abscesses, they were small and full; and just as likely to be the result of a few distinct tubercles, which had existed in the lungs previously to the inflammation, as of inflammation itself. Some persons will have an old tubercle or two formed in the lungs, without inflammation. That is what we see continually. These tubercles may suppurate, and an abscess be formed; and if the lung fall into a state of inflammation, the solitary abscess may be ascribed to inflammation. When abscesses do occur in the lung, I am satisfied that Laennec is right in asserting, that they are almost always occasioned by the softening of tubercular deposition,—the softening of scrofulous deposit. “Among several hundred dissections of peripneumonic subjects,” says Laennec, “I have not met with a collection of pus in an inflamed lung, more than five or six times. These were not of large extent; nor were they numerous in the same lung.” Even Broussais, to whom Laennec was in many points indebted, declares that he never saw ulceration in the lungs, without tubercles, more than once; and then the inflammation resulted from a musket-ball, which was tantamount to a tubercle. The reason assigned by Laennec for the rarity of an abscess in the lungs is, that the disease is either cured by art, or destroys life before it proceeds to the length of destroying the pulmonary tissue;—that death takes place before the disease advances so far, as for matter to be formed in the lung, in the form of an abscess.

Those cases of inflammation of the lungs which end in the existence of abscess, are marked by the same auscultatory phenomena, as occur when there is a phthisical excavation. We hear the sound come through the tube; and when the patient breathes, there is the sound of a cavity; and there is a metallic tinkling;—as if a bell were struck with the point of a pin, or something very fine.

*Its Progress.*—This disease is frequently fatal when it is not of great extent; and when it has not passed the first of the three stages to which I have alluded. The first and second of these stages, are frequently seen in different parts of the same lung; and so may even the third stage. We observe one stage going into another.

*Usual Seat of the Disease.*—It is very remarkable that, in the greater number of instances, the inflammation commences at the lower part of the organ; and it may not extend higher. Consequently, when the disease has advanced, it is in the lower part of the lung that the second or third stage is generally found; while higher up, the disease may be only in the first stage, or entirely absent. The right lung, it has been asserted, is more frequently affected than the left. Of that I cannot speak; but I can speak to the fact of inflammation beginning at the lower part of the organ, in an infinitely greater number of instances than higher up. There can be no doubt that the membrane of the air-cells, and not the surrounding cellular tissue, is the seat of the disease. In the second stage of the disease,—when the lung is solidified, but still red,—if the structure be cut or torn, instead of the natural appearance of the cells, the inflamed part has minute granules, round or oval;—corresponding exactly with the appearance which the air-cells would give, if filled with a tenacious fluid, and solidified. Indeed, Louis found that, by forcing fluid into the bronchia, the same granular appearance might be produced by art; and therefore this granular appearance clearly arises from the air-cells being filled with the same tenacious fluid. The crepitous or crackling rattle also, I think, shows the same thing; for it is heard in another affection, in which this thick fluid evidently exists in the air-cells. In hæmoptysis, when bleeding takes place in the air-cells, the same sound is heard as in peripneumonia. In hæmoptysis, this must arise from little bubbles snapping and cracking through this fluid; and as precisely the same sound is heard in peripneumonia, I think it is a strong argument to prove that the air-cells are affected by the disease; more especially when we see that a certain peculiar fluid is spit up in the affection.

*Progress of Amendment.*—If, by art, the disease be remedied,—if the inflammation yield, of course the lung goes through the same stages as before, but inversely. The third stage comes to the second, and the second to the first; and it is found that the signs audibly noticed by the ear, go through the very same inverted

course. The auscultatory phenomena heard in the second stage disappear; and those which occurred in the first stage are heard again. Nothing is more interesting, certainly, than to trace the reversed order of the changes here. Suppose the disease has only gone into the first stage, we hear the hollow sound on striking as in health; and, on listening, we hear a crepitous rattle, and even a crackling. But while the patient is being cured, the crepitous rattle declines;—it becomes fainter and fainter every day; and, instead of that, we have the natural murmur of respiration more and more distinct. Suppose the second stage has been reached, and we are successful;—in that case the want of a hollow sound, on striking the chest, gives way; and we hear, by degrees, a little hollowness of sound, which increases more and more every day; till that side of the chest sounds as hollow as the other. The respiration had ceased from the lungs having become solid; but we hear a little crepitous rattle, increasing every day, till it is heard as distinctly as in the first stage; and then, having arrived at the first stage, the disease passes through that entirely. The crepitous rattle declines; and the natural respiratory murmur becomes more and more distinct. I mentioned that, in the third stage, we still have no hollow sound; but we have a mucous rattle, generally from the entrance of pus into the bronchial tubes.<sup>a</sup> This declines by degrees, if the patient get better; and then we gradually hear a crepitous rattle, from the cells losing a part of their viscid contents; so that they again admit a portion of air. The chest then regains its hollow sound on striking; and, at last, the crepitous rattle declines.

Anatomical examination shows the changes of the part to be precisely correspondent with these auscultatory phenomena. When the first stage is recovered from, the lung is found to grow less red,—less turgid. Supposing the patient dies from intense inflammation of one part of the lungs, there is a lower degree in another part; and we find that is only in the first stage; but we are still able to make our observations there. Perhaps we have cured the inflammation at that one spot; respiration is heard there more and more; while in another part it is heard less and less. But the patient dies; and, by examining different parts of the lungs after death, and having listened to them through life, we are able to trace the changes.

When the inflammation of the third stage is being recovered from, the lungs become less turgid; and when the second stage is being recovered from, and the lung is going back to the first, the colour also becomes less intense; the texture becomes softer; the weight decreases; the organ, on comparison, affords more fluid; and the fluid becomes more and more of a frothy character. In the second stage, as I mentioned,<sup>b</sup> there is a considerable granular appearance; which declines in the third, and the vesicular character of the lung returns. When the third stage is recovered from, the yellow colour becomes lighter and lighter; the pus becomes more aqueous, less thick, and at length frothy; the accumulations of pus are reduced to mere specks; the vesicular appearance returns; the lung crepitates, and at length grows natural; and the little serous infiltration that existed is absorbed.

*Importance of the Auscultatory Signs.*—Notwithstanding that cases of peripneumonia are every day recognized, and the amendment or exasperation of the disease ascertained, by practitioners who never employ their ears (as though nature had given us ears to be used on every occasion, except when we are practising our profession); yet the observation of the auscultatory signs, in the three stages of peripneumonia, is sometimes more than a philosophical observation,—more than an intellectual gratification. Many cases of inflammation of the lungs, I know, have been overlooked in the midst of other diseases; or have been totally mistaken. It is vain for those who obstinately refuse to avail themselves of the means given us by nature (in the sense of hearing) for learning the phenomena of disease,—it is vain for them to assert, that they can form an accurate diagnosis on all occasions; for these persons are perpetually lamenting, that medical evidence is uncertain; and, to my certain knowledge, they do frequently mistake diseases of the lungs for diseases of the heart, and diseases of the heart for diseases of the lungs. In

<sup>a</sup> See Page 753.

<sup>b</sup> See Page 754.

the affection before us (peripneumonia), if it suddenly supervene during a chronic affection of the chest, they continually ascribe the symptoms to effusion, to pleuritis, to dropsy of the chest, or to something else;—having no idea whatever of the real disease. In phthisis, an aggravation of the dyspnœa, unattended by pain, is very common; and is ascribed to effusion into the chest, or the bronchia, or the substance of the lungs; and, in chronic bronchitis, such an aggravation is ascribed to an attack of spasmodic asthma; when the simple trouble of listening to the lungs would show crepitous rattle, and prove that the difficulty of breathing arises from the presence of peripneumonia. In various fevers (eruptive and simple), in simple dyspnœa (without pain), during an attack of rheumatism or of gout, peripneumonia is continually overlooked; and some surgeons have stated, that after severe wounds and operations, peripneumonia will occur in the most insidious manner; and will not be discovered till all possibility of remedy is over. Surgeons have lost patients under operations, after having suffered severe accidents, without knowing why; and, after death, they have discovered that the lungs were inflamed. This is a fact that is mentioned in many surgical books. All this mischief will be prevented by examining the chest with the ear, in every instance of dyspnœa whatever;—where there may be no pectoral symptoms at all;—no signs of any morbid affection of the chest; but where pectoral complaints are likely to supervene. This may be avoided by examining the chest, from time to time;—exactly as we feel it to be our duty, on other occasions, to ascertain not only the state of affected parts, but the state of the head, and of the abdomen.

*Causes.*—The causes of this disease are those of any other inflammation. I did not mention the causes of bronchitis; because in both diseases they are the same. Cold is a common cause; and so are vicissitudes of temperature;—cold and heat, applied in the way which I mentioned when speaking of inflammation.<sup>a</sup>—Both bronchitis and peripneumonia supervene on the other affections of the chest. Nothing is more common, than to see bronchitis and peripneumonia united with diseases of the heart and pericardium; and so nothing is more common, in diseases of the lungs, than to see these affections. In phthisis we have bronchitis (acute and chronic) and peripneumonia; and so in every other disease of the chest. Inflammation is frequently idiopathic,—arising from a common cause; but sometimes it is symptomatic;—being the mere result of another disease in the neighbourhood.

*Treatment.*—On the treatment of the disease, I shall not dwell. It is only the treatment of any inflammation. Patients have sometimes borne the loss of an immense quantity of blood:—perhaps more in this disease than in most others. It is in this affection that those enormous bleedings, which I mentioned when speaking of inflammation in general,<sup>b</sup> but of which I have no experience, are reported to have taken place;—a few gallons in the course of a few days. Mercury is of the same use in this affection as in bronchitis; and in bronchitis as in other inflammatory diseases.

[In cases of ordinary acute pneumonia in the adult, the inflammation occupies a continuous portion of one or more lobes, and hence is called *lobar*, to distinguish it from that variety in which the inflammation attacks isolated lobules; thus giving rise to the formation of a number of hardened masses, separated from one another by healthy tissue. This latter is called *lobular* pneumonia, the diseased portions presenting the same changes in colour, density, &c., as in lobar pneumonia, to which latter the description in the text is chiefly applicable.]

Usually, pneumonia is confined to one lung, and even here it is rare to find the whole lung affected. Most commonly it is limited to a part of the organ, and especially to one of the lobes; the interlobular fissures thus often forming the boundary line between the healthy and diseased portions. The right lung also is more frequently affected than the left, in the proportion according to Grisolle of 7 to 4. This difference in favour of the right lung is observed at all periods of life. The same remark does not hold good of double pneumonia, which although rare in

<sup>a</sup> See Page 113.

<sup>b</sup> See Page 123.

adults, is much more frequent in children. In lobular pneumonia indeed, which is especially met with in children between the ages of two and six years, both lungs are almost always attacked.

As regards the portion of lung most likely to be affected, it seems now pretty well established that the base is more frequently the seat of the disease than the summit; but the same preponderance in favour of the lower lobe does not seem to obtain, in advanced life or in new-born infants.

*Symptoms.*—In his account of the symptoms, Dr. Elliotson appears to attach too little importance to the sputa, as a diagnostic feature. The viscid rust-coloured sputa in question, are, it is true, not always present, but still very generally so during the first stage of the disease, and at the same time their aspect is so peculiar as to render them perfectly characteristic of the affection. It should also be mentioned in speaking of the physical signs, that in the second stage of the disease, or that of hepatization, not only is the percussion flat and the vesicular murmur absent, but the latter is replaced by a bronchial respiration, which seems to be produced by the passage of the air along the trachea and large bronchia, the sound of which is transmitted to the ear through the solidified pulmonary tissue.

The duration of acute pneumonia is very various. It rarely runs its course in less than a week, or extends beyond three. In favourable cases, resolution rarely takes place until after the disease has passed to its second stage. When it has arrived at its third stage, or that of purulent infiltration, recoveries are not frequent.

The resolution of this disease is perhaps more frequently accompanied, than in the case of any other inflammation, by phenomena which may be considered critical. Of these, more or less profuse perspiration and urinary deposits are the most frequent; the latter being sometimes spontaneous, and at others taking place only by the addition of nitric acid, or under the influence of heat. Diarrhœa, bloody urine, herpetic eruptions about the mouth, boils, parotids, &c., have also been met with.

The varieties of pneumonia are very great. Thus while at one time it is marked by the most highly inflammatory symptoms, at others it is characterized by typhoid phenomena, or by the presence of bilious symptoms, such as yellowness of the skin, of the sputa and other excretions. The extent of the disease, whether occupying one or both lungs, its form, whether lobar or lobular, the age of the patient, and other circumstances, give rise to important modifications.

It has been already observed that lobular pneumonia is especially met with in children. Indeed this is the form usually met with in those who are not over six or seven years of age. It is commonly ushered in by catarrhal symptoms, during which the respiration is but little accelerated, and often unaccompanied by any evidence of pain, and the fever slight. Auscultation discovers only such phenomena as belong to bronchitis, *i. e.* sonorous or mucous rhonchi. After a time the pulse and respiration become suddenly accelerated, the skin hot, with oppression, restlessness, dilated nostrils, and anxiety of countenance. Still, auscultation may discover nothing but a sub-crepitant rattle, and no appreciable dulness may be elicited by percussion. It is only in the more advanced stages that we have bronchial respiration and decidedly dull percussion, and even these phenomena are usually less marked than in the lobar pneumonia of adults. The pneumonia of children differs from the latter, not only in its symptoms, but in the circumstances of its origin. It rarely attacks a child previously in perfect health; but is most commonly the consequence of some other affection on which it supervenes, as measles, whooping-cough, &c.

In old people the symptoms of inflammation of the lung are often very obscure, at the same time that the danger is much greater than in the middle period of life.

The same obscurity often attends the inflammations of the lung which come on in the course of other diseases. When supervening in the course of severe acute febrile diseases, especially of a low grade, the access of pneumonia may be marked merely by a sudden increase of fever and prostration, and its symptoms are often masked by those of the principal affection. By the careful employment, however,

of auscultation and percussion, we may generally succeed in arriving at a satisfactory conclusion, where an aggravation of the symptoms has already led us to suspect that some fresh disorder has supervened upon the previous affection.

*Causes.*—As already observed, pneumonia is often a secondary affection, and here a variety of circumstances, different in different cases, may concur in producing it. When it comes on in the last stage of low fevers, or other diseases in which the system is greatly prostrated, its production is much favoured by the tendency to congestion in the most depending portions of the lungs, when the patient remains for a length of time in the horizontal position. When it supervenes upon tuberculous disease, the presence of these bodies must at least be a strongly predisposing cause. The same is true of organic affections of the heart and other diseases, which have a tendency to produce irritation and congestion of the pulmonary tissue.

The principal cause, however, of idiopathic pneumonia, is cold. Although met with in all climates, it is especially rife in cold regions, whilst between the tropics, it is least prevalent; and even then, it is more frequent in those sections which are subject to brisk variations of temperature, than where the latter is more uniform. It is most frequent, too, during the winter and spring, and diminishes rapidly as summer advances. The individuals most likely to be attacked, are those most exposed to atmospheric vicissitudes, as well as to those circumstances calculated to favour their influence, such as fatigue and privations. The greater prevalence of the disease amongst men, is probably mainly owing to this circumstance, that they are much more exposed to these causes than women. Finally, wherever a patient is able to trace his attack to any particular circumstance, this is found, in the great majority of instances, to be cold, such as exposure to a draft of air, a check of perspiration, or the like. Occasionally, however, it is traced to violent exertion of the lungs, the inhalation of irritating vapours, &c.

*Treatment.*—The treatment, as Dr. Elliotson remarks, is that of inflammation in general. Still, however, it may be well to notice some points more particularly.

The loss of blood has always been the great resource in the treatment of this disease. Not only does it lessen the inflammatory action, but it diminishes the amount of labour which the lung, already less able to perform its duty, owing to the engorgement of a part of its structure, is called upon to perform. By lessening the quantity of blood which passes through the organ, we lessen its activity. These circumstances, as well as the importance of the organ to life, render free venesection, wherever the general system will admit of its employment, especially important and useful, and often absolutely imperative. It is scarcely necessary to remark, that topical depletion by cups or leeches may be resorted to, after general depletion is no longer advisable, and is sometimes particularly useful in relieving the local pain and uneasiness.

Next to bleeding, one of the most powerful agents in controlling inflammation of the lungs, is tartar emetic in large doses. The quantities administered by some, have been enormous; but at present, most physicians who place their great reliance upon it, do not give more than six to twelve grains in the twenty-four hours. Its good effects are undoubted, and the rapidity with which the most distressing symptoms are often relieved under its use is said to be particularly remarkable. Several conditions, however, such as inflammation of the stomach or intestines, contraindicate its employment, besides which it may give rise to unpleasant effects. One of the most common of these, is inflammation, followed by a pustular eruption, and even ulceration, of the mouth, fauces, œsophagus, or even the stomach. At times, also, the system seems to be poisoned by its use, so that the symptoms of collapse, a small pulse, hippocratic countenance, &c., have supervened upon its employment, and terminated in death. For these reasons, perhaps, the practice has never been very extensively adopted in the United States, where physicians are more in the habit of resorting to the drug in smaller quantities, say two grains in the twenty-four hours, or perhaps of placing their chief reliance upon calomel.

This remedy, alone or combined with opium, is perhaps one of the most efficacious to which we can resort.

It is unnecessary to allude to all the usual adjuvants of an antiphlogistic course, in reference to diet and regimen. The patient should be kept perfectly quiet, his shoulders moderately elevated, and the most perfect repose enjoined, at the same time that the position should be occasionally changed, in order to prevent the congestion of blood in the depending portions of the lungs. The most rigorous diet should be enjoined, and mucilages with narcotics resorted to, to allay the cough and pain, and procure comfortable rest. The efficacy of blisters is doubted by some practitioners, and applied at too early a period, before the excitement is sufficiently reduced, they may, as is well known, aggravate the disease. At a later period, however, when the fever is reduced, the strength diminished, and the loss of blood no longer admissible, their favourable influence upon the resolution of the disease is attested by sound experience. At the same period of the disease, certain expectorant remedies, such as senega or squill, may be advantageously resorted to. It is scarcely necessary to observe, that in a disease which presents itself under such a variety of forms, corresponding modifications of treatment are demanded. Thus in one case, a typhoid tendency, in another, bilious symptoms, may predominate, and demand especial attention. When it supervenes in the course of another affection, by which perhaps the constitution is already debilitated, it is necessary to be very cautious in resorting to loss of blood or other active antiphlogistic measures.

In young children the abstraction of blood is a less important measure than in adults. Its good effects are chiefly limited to the outset of the affection, whilst at a later period its debilitating effects are much to be dreaded. Of internal remedies, mercury is the most valuable, and exercises the most decided control over the disease. It should be given in small and repeated doses, and a little castor-oil occasionally administered to relieve the bowels, when the abdomen becomes distended. There is not that risk in children of arresting the expectoration by the use of purgatives, which is to be feared in adults. Of the expectorant remedies, ipecacuanha is probably one of the best. Counter-irritation is highly important. Weak mustard poultices, onion poultices, &c., should be applied, not merely to the chest, but to the extremities. Blisters on young children, are apt to terminate in sloughing; and if resorted to, should be applied for a short time only, and followed by a poultice over the part. T. S.]

## CHAPTER VII.

### GANGRENE OF THE LUNGS.

*Seldom the Result of Inflammation.*—We might suppose that if the lungs ever became gangrenous, it would be the result of inflammation; as gangrene so frequently is in other parts of the body.\* But I believe that the severest inflammation of the lungs seldom, if ever, induces mortification. Sometimes it may be the case; but it is so rare that I have never seen it. The lungs will fall into a gangrenous state, and there is more or less inflammation attending it; but the gangrene does not appear to be the *result* of the inflammation. On the contrary, indeed, when nature makes an attempt to get rid of a gangrenous spot, inflammation is induced all around, in order to discharge it;—so that inflammation is sometimes the result of gangrene.

*Cases.*—In my own practice I have only seen two cases of this disease. They were of a different kind; and completely illustrated what Laennec has advanced on

\* See Pages 100 and 101.

the subject. On some points Laennec has brought our knowledge to perfection. In some cases nothing has been done since his time, and perhaps nothing *will* be done. In one of these cases, in my own practice, the gangrenous part was uncircumscribed. A large part of the lung was of an unnatural colour;—dark greenish, moist, and soft; and in some spots it was a mere putrid pulp;—little more than so much mud; and of an insupportable odour. In those parts of the lung which I saw, that were not in a gangrenous state, the organ was firm, and of a chocolate-colour, or a deep green. These appeared to be the three stages of the complaint. There was one part a chocolate-colour, or deep green, and quite firm; another part was moist and soft, and of a dark green; and the third part formed a perfectly putrid, soft, muddy mass. A large portion of each lung was in this condition;—in one of the three stages of this affection. In another case which I had, the gangrene was in more circumscribed patches or spots. There were patches of the lung, black, soft, moist, and offensive in the worst spots; and in other parts, where the lung was still firm, it was of a green hue.

No attempt, in this latter case of mine, had been made by nature to effect separation; but Laennec mentions that a gangrenous piece sometimes detaches itself, or is detached, from the surrounding parts;—just like a slough from caustic. That is an apt illustration of the appearance; because although the patches in my case were not separated, yet, if they had been, such would have been the state. The gangrenous part becomes dry and shrivelled;—just like a spot to which caustic has been applied; or it degenerates into a putrid paste, like mud. The surrounding structure is inflamed; as in other parts of the body when nature attempts a separation. When a dead part separates from the living by inflammation, the latter ends in ulceration;<sup>a</sup> so that the dead part is left without any connection with the living. The living part disconnects itself; the dead part becomes isolated; and is afterwards separated. If nature succeed, as she does sometimes, a cavity is often found where the gangrene existed; and this cavity has a lining membrane. Sometimes no cavity is left, but a cicatrix is formed; and the whole appears to have grown up together. This appearance has been perfectly well described by Laennec, and by others. In some instances, the separated portion makes its way into the pleura, and pleuritis is induced; and pleurisy, with effusion and pneumothorax, are the consequences.

*Symptoms.*—In my two cases,<sup>b</sup> the disease was marked by a sudden prostration of strength; a cadaverous alteration of the face; great feebleness of pulse; and an intolerable fœtor of the breath and sputa. One of these cases occurred in a man, who had long suffered from a loud hollow cough, with a copious frothy expectoration. The other occurred in a woman, who laboured under an encysted tumour of the pancreas. In her case a slight cough came on, which attracted no attention; and at last symptoms of gangrene appeared. These general signs will point out the disease, I imagine, much more than auscultation; but it is evident, that the gangrenous part must have less respiratory murmur than natural, that the part around will afford crepitous rattle, and that the cavity will give rise to pectoriloquy. If inflammation be set up for the removal of the slough,—causing the bronchial tubes to be affected,—there will be a “metallic tinkling;” but I imagine that far better evidence than this will be derived from the aspect of the patient;—from the cadaverous look, and the great debility; together with the intolerable stench both of the breath and the sputa.

*Diagnosis.*—When a part has become gangrenous, there is no hollow sound on striking the chest, and no respiratory murmur; but their absence may arise from numerous causes; and if any inflammation be set up around the dead part, to effect its separation, there will be a crepitous rattle; but no one could tell that this resulted from gangrene, rather than from some other cause. There are, however, certain signs observable by the other senses, which alone would make us believe there was gangrene; and these, together with the stethoscopic signs, make it tolerably certain. Sometimes the sputa, in this disease, are white and opaque at first;

<sup>a</sup> See Pages 101 and 102.

<sup>b</sup> See Page 759.

but they grow sanious, purulent, brown, and greenish; and they are, from the first, nearly as fetid as when the fœtor becomes gangrenous. This fetid odour of the sputa, however, cannot be much depended upon; nor can the fœtor of the breath. I have seen other diseases attended with extreme fœtor, but without gangrene; and I have seen extreme fœtor of the breath and sputa, without any danger whatever. Sometimes, in bronchitis, the fœtor both of the breath and sputa will be extreme. I mentioned having seen females, who were in tolerably good health, except that they spit up a little; and this expectoration was horribly offensive;—so that to stand near them was extremely unpleasant; yet they were walking about, and looking well.<sup>a</sup> I saw a case of this fœtor of the sputa, and smelling of the breath, in a person who died of phthisis. Occasionally the matter formed in phthisis is of such a quality, that the fœtor is much like that of the fœces. There is no danger *necessarily* from the extreme fœtor of the sputa, neither is there necessarily gangrene; but if, conjoined with this, we observe that the sputa are bloody, brownish, or greenish;—something like the discharge from a sloughing part; and when we observe any thing like little green fragments of lymph, together with a weak pulse, an elongated countenance, and a cadaverous aspect; and when the patient is in the same state as people who are sinking from mortification in any other part;—then there can be no doubt of the nature of the disease. But the mere putrid smell of the breath, and of the sputa, certainly ought not to make us conclude that the patient must have gangrene of the lung; or, indeed, be in any danger. In the two cases of this disease, which I had under my care,<sup>b</sup> the persons became, in a few days, very much emaciated. The pulse suddenly fell, the temperatnre declined, and the countenance expressed the most extreme exhaustion; but, at the same time, I must honestly confess, that I had no idea, in either case, of gangrene of the lungs; and was much struck with the appearance after death; I could then compare it with the symptoms I observed during life. They were hospital-patients; and it was only when opening them, that I discovered the disease. I smelt something very horrible when near them; but I ascribed it to another cause.

*Not necessarily Fatal.*—When gangrene does exist in the lungs, it is not necessarily fatal. There have been clear cases of gangrene of the lungs, which have been recovered from; though all the symptoms I have mentioned occurred. Nature is sometimes sufficient, when supported by good nourishment, to get an individual through an affection of this description; and to cause a separation of the gangrenous part.

*Treatment.*—There is nothing peculiar in the treatment. We must support the strength of the patient, as in other cases where there is an absence of inflammation, and the presence of extreme debility.

## CHAPTER VIII.

### HÆMOPTYSIS.

THERE is another disease of the substance of the lungs, and of the membrane of the air-cells; which, after death, presents very much the appearance of inflammation; and, before the time of Laennec, was frequently, (no doubt) mistaken for inflammation. This disease consists in the effusion of blood into the air-cells. I shall now, therefore, proceed to the description of hæmorrhage from the air-passages;—*hæmoptysis*.<sup>c</sup> This will be in conformity with the plan I have hitherto pursued; namely, that of treating first of inflammation, and then of certain other affections; among which is hæmorrhage.

<sup>a</sup> See Page 743.

<sup>c</sup> From *αιμα*, blood, and *πτυνω*, to spit.

<sup>b</sup> See Page 759.

## SECTION I.—HÆMORRHAGE FROM THE AIR-PASSAGES.

*General Characters.*—This hæmorrhage may proceed from the mucous membrane of the *air-passages*, or from the *air-cells*. In the one instance, it is not necessarily a dangerous disease; in the other it is highly dangerous, in as far as it is likely to be very profuse. The greater number of cases of hæmorrhage from the *air-passages*, arise simply from an effusion of blood from the mucous membrane of the bronchial tubes. The blood which is spit up is florid,—generally of a bright scarlet colour; and it is frothy. It is spit up with a tickling in the throat; the pulse is quick; and there is heat in the chest. This is the description of hæmorrhage, which takes place most frequently in young adults; between the age of puberty, and the full adult period of five-and-thirty. It occurs, particularly, in that period during which the chest expands,—in which we “spread,” as they say. The first part of life is disposed to hæmorrhage from the *nostrils*; the second to hæmorrhage from the *lungs*; and the third to hæmorrhage from the *abdomen*.

*Diagnosis.*—The disease, in general, is easily made out. The only difficulty is to distinguish between it and hæmorrhage from the stomach; but the latter is usually marked by a discharge of *black* blood. The blood is either discharged from the veins of the stomach; or it lies in the stomach so long after its escape from the vessels, that it acquires a venous hue. From the one cause or from the other, blood, when discharged upwards from the stomach, is generally black; and has also generally lain there long enough to be coagulated;—it is in clots, larger or smaller. Frequently, too, it passes through the pylorus, and is seen in the *feces*. Besides that, it frequently comes up with the food,—with the contents of the stomach; and, when it does not, still it comes up with sickness and nausea, if not with downright vomiting. We know that people may have a discharge from the stomach without vomiting: sometimes a quantity of fluid comes to the mouth, and even portions of food come up without vomiting; and so it is with the blood. Occasionally, however, it comes up with decided vomiting. There is frequently a great uneasiness about the *præcordia*, and a fulness about the liver and stomach. These symptoms are all absent in hæmorrhage from the lungs. The blood, too, is florid; and, instead of being mixed with food, it is frothy; and is necessarily mixed with air, in consequence of the parts from which it comes. These parts will not allow it to stay so long as the stomach; and it generally comes up as soon as it is poured into the passages; and therefore it is seldom coagulated. Occasionally, however, there is a little coagulum; for it will sometimes lie sufficiently long to become solid and black, before it comes up. In addition to this, we have pectoral symptoms in hæmoptysis; instead of nausea and vomiting, we have a “stitch” in the side, a little cough, and a tickling in the throat. On listening to the chest, when the blood is in the *air-passages*, we hear sibilous and sonorous rattles.

*Causes.*—This species of hæmorrhage occurs more particularly in those persons disposed to consumption; with a fine soft skin, soft hair,\* and a sanguineous temperament; and, among these, it occurs more particularly in those who have a florid colour. The disease sometimes occurs in those who have evident signs of inflammation; sometimes it occurs where there is hardly any thing particular to be perceived about the individual; and sometimes it occurs in those, in whom there appears to be great strength of system. It is produced by all the causes of inflammation.<sup>a</sup> A blow on the chest, or catching cold, will give rise to it; but it very often takes place without any observable exciting cause. Violent exercise, and excitement of mind or body in any way, will occasionally produce it; but sometimes it occurs without any apparent cause.

*Duration and Effects.*—It will return at certain periods,—at intervals of a month or a twelvemonth; and at last it will cease altogether; and the patient will then become the subject of consumption. It is very common for consumption to take

\* See Page 112.

place in patients who have had several attacks of hæmoptysis; but this is not a necessary occurrence. I know many persons who expectorated blood, fifteen or twenty years ago, and who are now quite well. If a person spit blood, he should avoid every thing which causes an irritation of the chest; but he ought not to condemn himself; for I have known persons spit a considerable quantity, again and again, and yet afterwards do perfectly well.

*Morbid Appearances.*—When these patients die, we find nothing unusual on examination. If we examine a person who has died of phthisis, and who expectorated blood before there were marks of phthisis, there will be found nothing to account for the hæmorrhage. It is a mere effusion from the mucous membrane; which will pour out blood without a rupture of the large vessels. Small ones will sometimes throw out a gush of blood. When treating of hæmorrhage in general, I mentioned that we sometimes open persons who have died of hæmorrhage from the stomach and intestines, without being able to find a vessel ruptured. It was clearly an effusion from a thousand minute orifices.\*

## SECTION II.—HÆMORRHAGE FROM THE AIR-CELLS.

Sometimes, however, hæmorrhage from the lungs is not of this description. It does not take place from the mucous membrane; but it is a particular disease, occurring in the air-cells; and in that case the hæmorrhage is generally very profuse; far more so than in other cases.

*Morbid Appearances.*—On examining patients after death, (for they frequently die of the disease in this form,) we find that certain parts of the lung have become exceedingly hard; and, if they be near the surface, the lung is seen through the pleura looking very dark. The lung appears variegated; and there are large black patches here and there. If they be deep in the substance of the lung, we cannot discover their extent; but on taking hold of the lung, hard patches are felt;—some as large as nuts, and some as large as walnuts. On cutting into them, we find they are of a deep-red colour; and no doubt, in former times, they have been mistaken for so many large circumscribed inflammations. These parts of the lung may be from one to four cubic inches in extent, and even much larger; and the redness is a deep damask-hue. Nay, it is sometimes so intense as to be black;—as dark as a black clot of blood. This portion of the lung is not only hard but heavy; and it will not crackle under the finger.

On cutting a portion of the lung in this condition, we observe the same granular appearance which, I stated, takes place in inflammation of the substance of the lungs.<sup>b</sup> This granular appearance, before the part is completely solidified, no doubt arises from blood being effused into the air-cells, and there coagulating. The blood coagulates in each air-cell; the minute coagulum of each cell becomes a little grain, and furnishes this granular appearance. The diseased parts are usually quite circumscribed; so that the surrounding portion of the lung is in every respect healthy. In inflammation of the substance of the lung, the diseased appearance is gradually lost in the healthy lung; but in this disease, in almost every instance, the affection is entirely circumscribed; so that within a hair's breadth of it (I might almost say) the lung is perfectly healthy. The case is really one of severe ecchymosis; only that the blood is effused, not into the cellular membrane, (as it is in ecchymosis of the surface of the body,) but into the air-cells. That the blood is effused into the air-cells, and not into the cellular membrane of the lungs, is proved by the blood being spit up. If the blood were not in the air-cells, but in the cellular membrane, it could not be expectorated.

*Symptoms.*—The great symptom of this affection, during life, is spitting of blood. Besides the symptom of repeated and copious hæmorrhage, there is cough, difficulty of breathing, heat in the front of the chest, flushing in the face, and at

\* See Page 137.

<sup>b</sup> See Page 754.

length great paleness of it. There is also a tickling sensation of the bronchia;—just as when hæmorrhage comes from the air-passages.<sup>a</sup> We cannot tell whether the blood comes from the mucous membrane, or from the air-cells, by any of the *general* symptoms; but when it is effused in very large quantity, there is a *probability* that it comes from the air-cells. It is said that as much as ten pints of blood have been discharged from the lungs, in this way, in forty-eight hours: and Laennec says that he has seen thirty pints thus spit up in fifteen days.

The disease may exist in so slight a manner, that no external hæmorrhage takes place. I have known this state of the lungs to occur, without any spitting of blood. The blood has been effused into the air-cells, coagulated there, and produced the hard lumps I have described; and, not having been followed by subsequent attacks, no blood has been expectorated. Old persons, who were never known to have spit up blood, have died from other diseases; and this appearance has been found in their lungs. As this lesion evidently results from sanguineous exhalation into the air-cells, and perfectly resembles the cerebral sanguineous exhalations which produce apoplexy, Laennec has named it “pulmonary apoplexy.”

I think all will agree with me, that this is an exceedingly absurd name. So far as there is great local congestion of blood and effusion, the phenomena are the same as are observed occasionally in apoplexy. But apoplexy is not a state of parts. It is a loss of sense and motion; occurring, for the most part, suddenly. Apoplexy is a stroke that causes persons to fall down senseless and motionless. In the words of Cullen,—“*Motus voluntarii fere omnes imminuti; cum sopore, plus minus profundo; superstitie motu cordis et arteriarum.*”<sup>b</sup> That is what we mean by “apoplexy.” If a person be said to have apoplexy, and we ask the individual how he knows it, the answer is,—“He has lost all sensation and power of motion.” There he lies in an insensible state; and we cannot rouse him.” Apoplexy does not consist in the morbid state of the brain; but in the symptoms which we observe; and those symptoms will take place from depression of bone, or from an effusion of fluid. Any thing which compresses the brain will produce, not congestion of blood, but a loss of sense and motion. Nothing of this kind, however, occurs here. There is no loss of sense or motion in this disease; and therefore it cannot be apoplexy. Merely because apoplectic symptoms arise from a congestion of blood in the brain, or from hæmorrhage into it, Laennec has thought proper to call this state of the lung “apoplexy.” Apoplexy will frequently arise from a secretion of *pus* pressing upon the brain, or from a secretion of mere *serum*;—without any congestion,—without any fulness of the vessels. This is the case when part of a vessel becomes ossified; so that it splits across, and allows the blood to escape into the brain. Thus we may have hæmorrhage without apoplexy; and we may have apoplexy without congestion, and without hæmorrhage. I cannot but think, therefore, that it is an extreme abuse of terms, and likely to cause great confusion, to call this disease “apoplexy of the lungs;” for there is no resemblance whatever between it and apoplexy,—properly so denominated.

*History of the Disease.*—It is not long that this disease has been known. Dr. Forbes, in his translation of Laennec, mentions (in a note) that, “in 1816, M. Léveillé appears to have read a memoir on this subject before the Academy of Sciences at Paris; and, in 1817, Dr. Hohnbaum, of Hildburghausen, published three cases of sudden and fatal effusion into the substance of the lungs.”<sup>c</sup> He says, the lungs were found distended with dark-coloured blood, partly coagulated and partly fluid; and were almost too large for the chest. In one case, the same kind of blood was found in the bronchia; and in the other in the pleuræ. The cases appeared to be nothing more than a laceration of the blood-vessels; and the patients appeared to

<sup>a</sup> See Page 762.

<sup>b</sup> “The voluntary motions almost all diminished; with stupor, more or less profound; the motion of the heart and arteries remaining.”—“*Synopsis Nosologiæ Methodicæ; Classis 2* (‘*Neuroses*’); *Ordo 1* (‘*Comata*’); *Genus 41* (‘*Apoplexia*’). See Note (a) to Page 25.

<sup>c</sup> “A Treatise on the Diseases of the Chest, and on Mediate Auscultation; by R. T. H. Laennec, M.D. Translated by John Forbes, M.D.” Part I; Book 2; Chapter 5. (Third Edition; Page 192.)

die from the effects partly of internal hæmorrhage, and partly of oppression of the lungs, induced by the effusion of blood. They died of syncope and asphyxia. From the suddenness with which it occurred, and its appearing to arise from a laceration of the vessels of the lung, producing congestion, Dr. Hohnbaum gave the name of "pulmonary apoplexy" to this particular case. But we must consider, that neither sudden death nor effusion constitutes apoplexy; for apoplexy is nothing more than a loss of sense and motion. In apoplexy the motion of the heart may continue; but volition has ceased, partially or entirely. There can be no doubt, however, that Laennec was the first *on the Continent* who gave a full and accurate account of the disease; which he did in 1819. The disease was really not understood fully, till Laennec wrote upon it at that time; and he then pointed out the common connection of this particular state of the parts, with profuse hæmoptysis. Yet it is singular, (and I may be excused for mentioning it, since there was no merit in it,) that I myself published an account of this affection, and gave the symptoms during life, and the appearances after death, some two or three years before that.

*Case.*—The case (which will show the course of the disease very well) was that of J. G., aged thirty-five, by business a gardener:—a mild and extremely steady man. He had laboured for two years under dyspnœa, pyrexia, cough, pain of the chest, and bloody expectoration. At length, profuse hæmoptysis came on. Various remedies were prescribed, but in vain; and he ultimately died exhausted. On opening the body, the surface of the lungs presented numerous hard, circumscribed, very dark patches, of various sizes,—from that of a sixpence to the size of a crown. A person not of the profession, would have supposed them so many mortifications. Blood, however, when accumulated in the small vessels, often causes (as Dr. Baillie has pointed out<sup>a</sup>) a counterfeit appearance of mortification in the stomach and intestines, and in many other parts. Such was the nature of these patches. On cutting perpendicularly through them, the hardness and dark colour were found extending into the lungs (an inch or less); in a form equally circumscribed as on the surface. The intervening spaces were perfectly healthy. This Laennec also remarked: Nearly the whole of the interior lobe of the right lung had undergone the same change as the circumscribed portions in the other lobes. This change consisted in a prodigious congestion of blood, which could not be squeezed out, and which gave the dark colour and hardness. The slices were quite diaphanous; and of a beautiful red colour. No other change,—no disorganization, was in any part discernible. It seemed as if the most minute vessels in various parts, had become dilated, as in *nævi materni*; and had thus allowed the escape of the blood. Had the symptoms been those of acute inflammation, and the blackness not been in detached portions, there would have been nothing singular; nor would there, had the disease been simply chronic inflammation;—indicated by a frequent pain at the anterior and lower part of the chest, always yielding to blisters, and a large quantity of bloody fluid found in the cavities of both pleuræ after death. But it is surprising that this should occur in patches; and should have induced no suppuration,—no disorganization; but merely hæmoptysis and pain.

There was no great discovery here. I opened the man; the appearances were provided for me; and I described them. I pride myself on one thing;—that I did not call it "apoplexy of the lungs." I gave it no name.<sup>b</sup>

*Signs afforded by Auscultation.*—The employment of the ear, in addition to the general symptoms, may be useful in this disease. It is always desirable, when a person spits blood, to know how much disease exists in the lungs; and it is desirable to know whether the blood comes from the bronchial membrane, or is the consequence of such a state of the air-cells as we have noticed;<sup>c</sup> because the

<sup>a</sup> In his "Morbid Anatomy," Chapter 8; Section I.

<sup>b</sup> The work in which the case was published, was called the "Annals of Medicine and Surgery." I made an extract from it in my work on Diseases of the Heart (Page 32);—the original publication being now very scarce.

<sup>c</sup> See Page 763.

latter form of hæmoptysis is far less manageable than the former. In this kind of hæmoptysis (called "pulmonary apoplexy"), when only a little effusion has taken place, there is a crepitous rattle; but in hæmoptysis from the air-tubes, there is not; and for this reason,—the blood is not in the air-cells. When it is in the *tubes*, we have no crepitous rattle; for that always arises from an accumulation, of some kind or other, in the *cells*. In effusion of blood in the air-cells, we have crepitous rattle *at first*; but where the blood is more *abundantly* effused, we cannot have crepitous rattle; because no air can be admitted. The crepitous rattle, I have no doubt, arises from the air passing through the fluid; and from the air-bubbles bursting one after the other. When so much blood is effused into the different air-cells, that no air can be admitted into them, and the part becomes firm, there is no crepitous rattle; nor, indeed, any rattle at all. No respiratory murmur, and no morbid respiration is heard; for no respiration can take place long in that part. All that can be detected by the ear is, that the part is not healthy. On striking over the part, it sounds dead; and on listening, there is no sound of respiration; and we learn very well, by the ear, what is the extent of the mischief. In the case I met with, the whole of the inferior lobe of one lung had become quite solid. In those days, the stethoscope was not invented; and therefore I knew nothing of the symptoms that would have presented themselves, if I had resorted to auscultation. But if I had employed the ear in that case, no respiration would have been heard over a great part of the chest; and on striking, there would have been no hollow sound; and therefore I should have known the extent of the mischief. The extent of mischief, in this disease, may be accurately learned. We may ascertain how much of the lung is solidified, by the extent of a *dead*, instead of a *hollow* sound, on percussion; and the extent to which there is no respiratory murmur. With regard to the *treatment*, that must be the same, whether the blood come from *one* part, or from *another*; and therefore it must be for the sake of the *prognosis* that we employ the ear, and make a distinction between the two cases;—the one being a manageable kind of affection, and the other extremely *unmanageable*.

[Later observations have not confirmed the idea that spitting of blood is the great symptom of pulmonary apoplexy. On the contrary, in the great majority of cases where the hard masses, or hæmorrhagic engorgements, described by Dr. Elliotson, have been found after death, no spitting of blood has taken place. In the few cases where a very profuse hæmorrhage is met with, no value can be attached to the latter as a diagnostic sign, since the same symptom is met with under other circumstances. The general absence of hæmoptysis in cases of pulmonary apoplexy is not astonishing, when we recollect that the blood is effused into the pulmonary tissue. In instances however, where the effusion is very great, rupture may occur, and blood may then escape in considerable quantities. Cases are reported in which the rupture has taken place into the pleura. We should further recollect that pulmonary apoplexy may be accompanied by hæmoptysis, at the same time that the latter is no consequence of the former, for both species of hæmorrhage, that into the bronchial tubes, constituting hæmoptysis, and that into the proper pulmonary tissue, constituting pulmonary apoplexy, may be the joint result of a common cause, most usually of some circumstance which occasions obstruction to the passage of blood through the lungs. Pulmonary apoplexy indeed, is especially met with in connection with organic diseases of the heart, particularly where there is obstruction to the passage of blood through the left side, with hypertrophy. Besides its occurrence in the course of some chronic affection, it is also met with in fevers, where its production must in great measure be attributed to that condition of the blood and tissues generally which favour the production of hæmorrhage.]

As regards the diagnosis of the disease, it is exceedingly obscure. In very many cases, its presence is revealed only by a post-mortem examination. There is nothing characteristic in the physical signs to which it gives rise, and their combination is not often such as to render the diagnosis clear. [T. S.]

## SECTION III.—TREATMENT OF HÆMOPTYSIS.

*General Treatment.*—On the immediate occurrence of hæmorrhage from the lungs, it is right to treat it as inflammation;—to bleed in the arm freely; and to set the patient upright, and keep him so; in order to make him feel as faint as possible. We should keep him in that position, instead of allowing him to lie down. It is safe to apply ice to the front of the chest; and this, I think, should always be done. There can be no impropriety in it. As soon as we have bled, until ice can be procured, we should throw cold water on the chest; and endeavour to produce a contraction of the end of the vessels;—in the same way as we proceed in the case of the womb. But generally the bleeding soon stops; for a patient seldom dies of hæmoptysis at the time. Bleeding at the arm, throwing open the windows and doors, and taking the clothes off the chest, answer very well. The patient should not be allowed to move. He should be made easy and comfortable; but he should not be allowed to move, or to speak. I have often made persons persevere, for a fortnight together, after dangerous hæmorrhages;—making them write for whatever was wanted. It is proper to starve the patient; to give him nothing but plain water, milk and water, lemonade, or things of that description; and it is surprising how patients, in this disease, bear cold. I know not a single instance of a person suffering inflammation of the chest, from all this exposure; notwithstanding that, in other circumstances, he would (in all probability) have suffered severely.

*Acetate of Lead.*—The best internal medicine, by far, is the acetate of lead; and this must often be given in considerable quantities, before it will stop the hæmorrhage. Within a month, I have had three cases of hæmoptysis; in which I have been obliged to give as much as three grains every four hours, before I could fully stop the discharge of blood. It is always safe to begin with *one* or *two* grains, every *six* hours; but if the hæmorrhage does not stop, but returns every day, it would be right to give such a quantity as this every *four* hours; and if that does not stop it, we may give *three* grains every *three* or four hours, with perfect safety. In all the three cases, the last mentioned doses were given; and no inconvenience was felt, except from constipation; which was remedied, every day, by some laxative. If we do not attend to the state of the bowels, and procure a motion every day, the patient may become the subject of colic; but by administering croton-oil, or castor-oil, or some purgative that contains no sulphuric acid, there will seldom be any colic or pain of the bowels; which is very troublesome. Some persons give opium, to prevent griping; but I have not done so; because I have not found it necessary.

*Mode of administering Lead.*—Some persons give the lead in a *liquid*, and some in a *solid* form. I have not exhibited it liquid, because it is very nauseous; and it answers just as well solid. It mixes up with the extract of colocynt into pills, very well; and I have seen the stomach bear it, if given in a pill, much better than in the fluid form. That is the case with all acrid and nauseous things;—the stomach can bear a pill the best.

*Hydrocyanic Acid.*—If the patient's stomach be disposed to reject it, it is useful to give one or two minims of hydrocyanic acid, three or four times a-day. If we are giving the lead only three times a-day, then we might give hydrocyanic acid three or four times; but if the lead be administered every four hours, then we cannot give the prussic acid so frequently. The dose required to prevent vomiting, is exceedingly various. In some it will be prevented by one minim, three or four times a-day, taken before the lead; and in other cases, two, three, or four minims, will be required. Of all medicines to prevent others from irritating the stomach, I know of none equal to hydrocyanic acid.

Some apply blisters over the chest; and they are very useful in these cases *at last*; but the application of cold, by means of ice, is better. If the means which I have recommended be adopted, we shall generally be able to control the affection. Treat it, in the first instance, as an *active* inflammation; and when the hæmorrhage

is very considerable, treat it as a *passive* inflammation; or rather combine the two modes of treatment. Do all that can be done to prevent an excitement of the pulse, by bleeding from time to time, and keeping down the circulation; and at the same time adopt the treatment for passive inflammation, by producing a constriction of the vessels.

## CHAPTER IX.

### FUNCTIONAL DISEASES OF THE LUNGS.

BEFORE I describe *organic* diseases of the lungs,—those in which there is a new deposition, or a transformation, or lesions of the substance,—I will consider *functional* diseases of those organs. I will speak first of asthma, and then of hooping-cough. Asthma is often connected with bronchitis and hooping-cough; and very often with inflammatory diseases; but not *necessarily* so. Both asthma and hooping-cough are frequently unconnected with inflammation; nor is there any appearance, after death, that will explain the symptoms. They are frequently specific and functional diseases.

#### SECTION I.—ASTHMA.

*Definition.*—By “asthma”<sup>a</sup> is meant a spasmodic difficulty of breathing;—a spasmodic affection of the organs of respiration, below the larynx and trachea. It is frequently united with organic diseases, or with inflammatory states; and frequently it is merely the result of irritation; so that we may have it without any organic disease, or any inflammation at all.

*Symptoms.*—In a case of asthma,—pure, genuine asthma,—there is a violent sense of constriction of the chest, with a loud wheezing respiration;—heard without putting our ear to the chest, or employing a stethoscope. We hear a patient, at some distance, wheezing and breathing for his life. Such an attack as this, is soon accompanied by a short and difficult cough; but as the sense of constriction goes off, the cough becomes freer and deeper; and there is some expectoration.

During this attack, the face is pale, elongated, and pinched; the nose and extremities become cold; the pulse is found to be small and quick; and I have frequently observed it to be irregular. The skin, throughout the body, becomes rough,—from the retrocession of blood from it; horripilation takes place; and the patient looks as if he were dying. He is cold and pale, and gasping for breath; and in such an agony, from the want of it, that one would think him dying; yet, in the greater number of cases, there is no danger whatever.

*Usually occurs in the Night.*—Such an attack as this, may last only a few minutes; or it may last several hours. It generally takes place in the middle of the night. The gout, when it first attacks an individual, generally does so in the middle of the night;—that is to say, at two or three o’clock in the morning; and this is generally the case, likewise, with asthma. When it first invades, the patient jumps up in bed; throws off the clothes; draws aside his curtains, if he have any; often goes to the window and throws it open also, as he does the door; and stands at the window, to get as much air as he possibly can. After a certain time, he finds that he breathes more easily, can take a deeper inspiration; begins to cough more deeply, and to expectorate; and then he goes to bed again, a great deal better. Very often, at the same time the next night, the scene is repeated.

<sup>a</sup> From *ασθμαζω*, to gasp for breath..

*Premonitory Symptoms.*—When a person is subject to this occurrence very often, the breathing, for the most part, is not quite free in the intervals. It is generally difficult; the patient feels that all is not right; and, at the same time, there is generally a great degree of flatulence. A large quantity of wind undoubtedly is produced in the stomach. It could not be generated so rapidly by any chemical process;—for persons in this condition, just like hysterical women, become, in a moment, filled with wind; which comes forth in torrents, apparently interminable; and this occurs without any thing being in the stomach, to promote the production of it. I think there can be no doubt (and John Hunter was of this opinion) that air can be secreted like a liquid; for we see a woman in a moment, from a passion of the mind, swell out and pour forth torrents. I believe the wind, in these cases, is always inodorous. The gases from the alimentary canal, have been analyzed by the French; and their nature has been ascertained from the contents of the stomach and intestines. An account of this may be found in Majendie's work; but whether the wind just referred to has been analyzed, I do not know. I think it has not. At the same time, there is generated a very large quantity of liquid, which is quite pale;—containing very little saline or animal matter. They are as pure specimens, both of wind and water, as can be produced (I suppose) from the animal body.

Some persons have these attacks only at certain seasons of the year; and some only in particular places. If they be subject to the affection, they are rendered far more liable to it by eating what is ill-suited to their stomach;—eating articles which they have found not to agree with them. Sometimes indigestion precedes an attack of this description; sometimes there are symptoms of disturbance of the nervous system,—such as sleeplessness and headache; and sometimes there is a great itching of the skin. These circumstances occasionally precede the disease.

*Attacks Persons of all Ages.*—The occurrence of the disease is very various. Some have it only for a few nights; and some for many weeks. It is a disease which attacks all ages. I have seen it, over and over again, in infants at the breast; where, from the very slightest degree of bronchitis,—the slightest catarrh, they have been seized, at different periods of the day, with violent wheezing; and that wheezing has ceased almost as suddenly; and therefore I have no doubt it was asthma. I have seen several instances of it, as I suppose, in boys below puberty and above it; and very frequently it attacks young adults. Persons may be subject to a recurrence of this affection for many years; and then it may cease entirely, without being followed by any other disease. A patient may, at one period of his life, entirely cease to be asthmatic; and this complete cessation of the disease may occur at all ages. With some persons, asthma occurs only in particular seasons, from particular circumstances, and from particular states of the weather; but with some the tendency to it is so strong, that they are sure to have it wherever they are. There are always exciting causes sufficient to produce the disease in them;—so extreme is their liability to it.

*Sometimes attended with Pain.*—I have sometimes seen it attended with very great pain. There has appeared to be a violent spasm of the respiratory muscles; so that patients have had violent pain; and yet, without any bleeding,—simply from stimulating remedies,—this pain has ceased.

*Varieties.*—Although this which I have now described, is the regular form of the disease, yet (like epilepsy<sup>a</sup>) it sometimes puts on very great irregularity. Some persons, in the fit, will make a crowing noise. Some will have a number of deep inspirations successively: and then they will suddenly cease to breathe. There is every sort of variety that can be imagined; but still, no doubt, they all deserve the name of “asthma.”

*Complications.*—The disease is literally pure spasm, and does not necessarily depend upon any organic cause. But it may be combined with any inflammatory disease of the chest; and it may be combined with any *organic* disease of the chest. Even the slightest pressure, in some people, will cause this affection. Mr.

<sup>a</sup> See Page 598.

Lawrence (as I before mentioned) has described a case, in which violent paroxysms of asthma were induced, simply by an aneurism of the innominate;—causing the least possible degree of pressure upon the trachea.<sup>a</sup> The disease with which asthma is most commonly united, is chronic bronchitis. When persons labour under the latter affection, besides constant difficulty of breathing, they are subject to great aggravations of this difficulty, from time to time;—particularly at night. As in this case they spit up a great deal, the affection is called, by the old writers, “*humoral asthma*.” But we continually have chronic asthma without chronic bronchitis; just as we may have the latter without any tendency to a spasmodic affection. Sometimes asthma is united with pleuritis and pneumonia; and on bleeding such patients, we have buffy blood; but in a case of genuine asthma, it is rare for the blood to be buffy. I do not know that it *ever* is so. Asthma is frequently seen united with diseases of the heart; but then it is to be remembered, that nothing is more common, in organic diseases of the heart, than for *chronic bronchitis* to exist. The heart is seldom organically diseased, to any considerable extent, without the bronchia being more or less inflamed.

*Diagnosis.*—The disease is easily distinguished from hydrothorax. On striking all over the chest, we have a clear sound; and, on listening, we have respiration all over the chest;—which we cannot have if any part of the cavity be filled with water. It is distinguished from bronchitis, by the absence of sonorous and sibilous rattle, except in the upper parts. Down below, throughout the rest of the chest, we do not hear those peculiar sounds of bronchitis; or, if we do hear something like them, they suddenly cease; and then there is the sound of health; but while bronchitis lasts, we have sonorous and sibilous rattle; and these only subside either from the interference of art, or the disease itself ceasing. In general, a loud respiratory murmur is heard all over the chest;—louder than it should be. The absence of other diseases, together with the suddenness of the attack, the suddenness of its cessation, and its extreme aggravation from time to time, will enable us to form our diagnosis.

*Prognosis of the Paroxysm.*—The prognosis in this disease, so far as the *paroxysm* is concerned, is generally good; but I have seen people die from pure spasmodic asthma. I recollect a young man, who had been asthmatic, being brought to the hospital in a great fright; and, when I saw him, he was dying. He could only breathe while on his knees and elbows. No signs of any other disease were found during life. He was cold and pale, and the pulse was not to be felt; and, in the course of two or three hours, he died. He had been accustomed to asthma; but this fit produced such a severe asthmatic state, that he did not survive. On opening him, no signs of disease were found; but the lungs were all distended; had lost their contractile power, so as to be unable to collapse; and were as light as a feather. I have read accounts of death from asthma; but it is a rare occurrence indeed.

*Prognosis as to its Termination.*—The prognosis, however, must be unfavourable as to the *termination* of the disease. Some persons will be liable to it for life, if they live in particular situations, in spite of all that can be done. We have a prognosis to make as to the *paroxysm*, and one as to the *duration* of the disease. The one is favourable, and the other unfavourable; but then the prognosis respecting the distant event, must depend upon the existence of other diseases. People labouring under asthma, often live to a great age; and the disease often ceases of itself. But we must always consider, in these cases, that there may be some other disease;—chronic bronchitis, chronic pneumonia, or disease of the heart; or there may be a tendency to phthisis; and all these things must be taken into the account, in forming a prognosis. Dr. Heberden<sup>b</sup> mentions two cases of the cessation of asthma, after it had existed some time: and he also mentions other cases of persons suddenly ceasing to be asthmatic; and never having another attack, though they have lived thirty years afterwards. I have myself known instances of its cessa-

<sup>a</sup> See Page 720.

<sup>b</sup> In his “Medical Commentaries,” Chapter 11. (First Edition; Pages 62 and 63.)

tion, after having existed a considerable time. But we can never prognosticate this. If it turn out so, it is all very well; but I think we have no means whatever of *predicting* that it will thus terminate.

*Predisposing Causes.*—The predisposing causes of the disease are not known. Very often it attacks those who are thin and pale; but they have pure, simple, spasmodic asthma. It as frequently, however, attacks those who are short and full,—bulky; and these generally have a combination of asthma and chronic bronchitis. They expectorate a great deal;—have “*humoral asthma*.” Of the real predisposition, however, we certainly do not know the nature. We know it is often hereditary. Asthma attacks many, whose parents (one or both) or whose grand-parents have had the disease. It runs in families.

*Exciting Causes.*—With regard to the *exciting* causes of the disease, they are (in general) cold and damp, and especially fogs. Some persons have it only in cold weather; others have it only in damp, foggy, moist weather; but there is a great variety in this respect. Some persons have it only in summer, and are all the better for cold weather; and some never have it but in particular situations. Most people are better in the country, if it be a dry place; but some are better in London; so that persons who have made their fortunes, and retired to the country, have become asthmatic; and have been obliged to return, and live in London again. I have read of cases, where parties have been obliged to go back to an old house in Thames Street. I recollect that particular street;—as damp and dirty as any in London.

*Hay-Asthma.*—In some persons, this disease is only induced (as it would appear) from particular exhalations from the vegetable kingdom;—the emanations from grass in flower. These are the people who have asthma only in summer; but by far the greater number have the disease aggravated in winter, and are pretty well in summer. Some, however, are never asthmatic till about May or June. I should think all these cases may be resolved into that particular form of disease, which has been called “hay-fever,” or “hay-asthma.” In some cases, there is a simple spasmodic affection of the breath; and in others, there is a violent catarrh, united with the spasmodic affection. This is a disease which has only been noticed of late years; and respecting which I have some curious facts to adduce.

*History of Hay-Asthma.*—Certain writers have spoken of what they call “a summer cold;”—“catarrhus æstivus.” The first medical composition that I read upon the subject, and the first that I ever knew to exist, was by Dr. Bostock, the celebrated chemist. It was from him I learned that some writers spoke of catarrhus æstivus; but I do not know to whom he alludes. Dr. Bostock states, in the tenth volume of the “*Medico-Chirurgical Transactions*,”<sup>a</sup> that at a certain time of the year he begins to sneeze,—has a “running” of the eyes, and all the other symptoms of catarrh; and that these continue for a certain length of time, wherever he is, and whatever he does. In a second paper, published by him in the same work,<sup>b</sup> he again refers to the subject; and relates his own case at considerable length. Before that time, I had heard people talk about “hay-fever” and “hay-asthma.” I was told that certain distinguished personages had “hay-fever.” It appears to be quite an aristocratical affection;—not at all visiting hay-makers, or those who have to do with hay and straw. I never met with such a thing in practice; and it appeared to me to be a highly gentleman-like, and indeed (I may add) *noble* affection. I could not tell what to make of it; and I disregarded it entirely;—supposing it to be a sort of aguish or hypochondriacal affection, of which those who had little to do, frequently became the subject. I happened, however, to be attending in a family, where the mother of the lady was said to have been the victim of it many years. She was a very sensible and superior woman; and she stated that, at a certain time of the year, when the grass came into flower, she was dreadfully distressed in breathing; and was obliged to leave her house, and go to as barren a place as she could find at the sea-side; and there she obtained comparative ease. She

told me this had been the case for many years; and that she had tried every thing in vain; for nothing did her good. She was not the only member of the family afflicted with it; for an uncle, some of her nephews and nieces, and some of her cousins, laboured under it. It was decidedly an hereditary family matter.

As there are some curious features in these cases, I alluded to them in a clinical lecture delivered at St. Thomas's Hospital. I knew that the course of which that lecture formed a part, was being published;<sup>a</sup> and I thought the shortest way to make the subject known, would be to mention it then. The consequence was, that I received several exceedingly kind letters, from gentlemen unknown to me; giving me facts upon the subject; and as the matter is very interesting, I will insert a few of them.

*Mr. Gordon's Cases.*—One of these letters was received from Mr. Gordon;—a surgeon residing at Welton, near Hull, Yorkshire. He stated that, in the "Medical Gazette," he had described the very same thing. I was not aware of it at the time; or I should have felt it a great pleasure, as well as my duty, to refer to it. He says:—

"I have this evening received Number 186 of the 'London Medical Gazette,' dated June 25 [1831].<sup>b</sup> It contains<sup>c</sup> the report of a clinical lecture which you delivered at St. Thomas's Hospital, in March last,<sup>d</sup> on the subject of hay-asthma.

"In consequence of your expressing a wish to receive information on this extraordinary complaint, I have taken the liberty of troubling you with this letter. I beg leave to state, that I have witnessed several instances of hay-fever, and hay-asthma, and, in the eighty-seventh number of the 'London Medical Gazette,' bearing date August 1, 1829,<sup>e</sup> I published a short account of the nature, symptoms, causes, and treatment, of these curious disorders. In that memoir I have observed, that the best preservative against their attack, is the cold shower-bath. For the last two seasons, however, while employing this, I have administered the sulphate of quinine, with the sulphate of iron:—the former in doses of two or three grains, the latter in doses of one grain, three times a-day. The success which has attended this prophylactic treatment, has exceeded my highest expectations. With two of the most severely afflicted of my patients on whom it has been tried, it has answered so effectually, that both of them have this year [1831] been able to walk through a rich meadow, without suffering in the slightest degree; although formerly, if they had ventured out into such a situation, they would have brought upon themselves all the agonies of spasmodic asthma.

"The symptoms I have related, were taken principally from the cases of\*\*\*\*\*. These two gentlemen have been annually attacked with hay-asthma, for the last fifteen or twenty years. They consulted Dr. B., and most of the eminent English physicians, as well as several practitioners on the Continent; but derived no relief from what was prescribed for them. By means, however, of the shower-bath, the quinine, and iron, they have, for the last two years, obtained a complete emancipation from their tormenting disorder."

*Another Description of Hay-Asthma.*—Another letter is from a practitioner at Bristol, who says,—"I knew nothing about hay-fever, as any definite disease; but your description of it is, with little exception, a very accurate detail of what I have suffered, every June, for several years."—Here was a gentleman who had been ill every summer, for several years, without being aware what his particular complaint was.—"Were I not," he proceeds, "at the present time annoyed by this troublesome affection, I should probably not have found leisure to give you the trouble of reading any thing on this subject.

"The attack generally begins, with me, at the latter end of May; with great itching of the eye-lids;—particularly at the inner canthi; from which I regularly, during this month, extract some cilia, which grow very near the cornea, and increase the irritation. My most troublesome symptom is sneezing. It is of a violent kind; and

<sup>a</sup> In the "London Medical Gazette;" Volumes 7 and 8.

<sup>b</sup> Volume 8; Page 384.

<sup>d</sup> March 31, 1831.

<sup>c</sup> At Page 411.

<sup>e</sup> Volume 4; Page 266.

often continues eight or ten times. The defluxion from the nostrils is most copious at these periods of the day; while, in the intervals, I have no catarrhal symptoms. Expectoration of clear mucus is also considerable. My sneezing attacks are sure to come on while I am visiting my patients;—to my great annoyance. This comfortless state generally continues five or six weeks; but is never sufficient to interrupt any of my employments, or render any confinement *necessary*; though I am always free from it when in the house. How far grass or hay has any thing to do with this affection, I cannot satisfactorily determine. There certainly are several hay-fields within a quarter of a mile of my house. The *air* seems to make me worse; and an open window is my abhorrence, while I am thus indisposed. Last week I spent an hour or two in a friend's hay-field, with a party of ladies; but the syllabub, the ladies, and the pastoral sports, had no amusement for me; and I was glad to get to a corner of the park, where my streaming eyes and nostrils, and noisy sternutations, might escape both remark and commiseration. Certainly, during that afternoon, in the hay-field, was the worst attack I have had; but whether it was the *air* which was cooler than usual, or the *hay*, I could not tell. I must however confess, that my *fancy* on the subject has always leaned more to the effect of some subtle particles, of an irritating nature, than to the ordinary causes of catarrhal affections. My lungs are rather asthmatic;—formerly I had a good deal of asthma. I have never found time to try any remedies; but shall certainly bear in mind yours, should I have this visitation next year."

*Dr. Bulman's Case of Hay-Asthma.*—I have another letter from Dr. Bulman, of Newcastle-upon-Tyne. He has given me several cases; of which the following is one:—"D. B., aged sixty-six, is of a spare but robust habit, and free from any constitutional or hereditary affection;—except, perhaps, the gout. He has been liable since his seventh year, if not sooner, to annual attacks of the disease so ably described by Dr. Bostock, under the name of '*catarrhus æstivus*.'<sup>a</sup> The disease invariably commences (about the second or third week in June) with a sense of uneasiness, heat, and itching in the '*tunica conjunctiva*;' but the itching is more particularly severe along the tarsus, and in the '*caruncula lachrymalis*.' On examination, this membrane is found to be considerably inflamed; but, except in the severer attacks, the inflammation does not extend to the eye-ball. The symptoms before mentioned are attended with watering of the eyes, increased secretion from the Meibomian glands, a sense of fulness or rather distension of the eye-ball, intolerance of light, and weight in the forehead. The itching gradually increases in violence, till it becomes almost insufferable;—compelling the patient, notwithstanding every resolution to the contrary, to rub his eyes; by which it is always considerably allayed.

"In the course of a few days, but sooner if the patient has exposed himself to the sun, the inflammation extends to the Schneiderian membrane of the nose; and is attended with itching and stuffing of the nostrils, increased secretion of mucus, and violent paroxysms of sneezing; which are also excited by dust of any kind, exposure to the heated external air, effluvium of new-made hay, and the odour of the bean-flower;—perhaps, also, by other odours. As this disease continues to advance, the membrane of the fauces and lungs is affected;—giving rise to a sense of dryness and extreme itching or pricking in the throat, to slight cough, with tightness of the chest, and difficulty of breathing; but there is little or no expectation.

"There are several paroxysms daily; commencing with intolerable itching and tingling of the eye-lids, and followed by the most violent fits of sneezing, accompanied by a copious discharge of mucus from the nasal passages. After this the patient obtains a longer or shorter respite; for the paroxysms occur at uncertain intervals; save that one invariably takes place about an hour after rising in the morning. The tightness of the chest and difficulty of breathing, though sufficiently distressing, have seldom been very urgent; but on two occasions they rose

<sup>a</sup> See Page 771.

to such a height, that the patient conceived himself in danger of instant suffocation. In severe attacks the eye-lids become œdematous. During the whole course of the disease, the patient is languid and listless; and, though restless, is averse to motion. His temper is more irritable than natural; but his pulse is scarcely, if at all, affected. His bowels are regular, and his appetite rather increased than diminished.

"The disease continues till about the end of July, or the beginning of August; when it almost imperceptibly declines; and it is remarkable, that the patient is then able to expose himself to the hottest sun, without the recurrence of any of the above detailed symptoms;"—showing, of course, that it does not depend upon the temperature;—"and indeed, during the violence of the disease, exposure to the open air early in the morning, and in the evening after sun-set, causes but little inconvenience. The patient has had attacks of this disease in France, Switzerland, and Italy. In the two former countries it was as severe as in England, but not more so; and it is extraordinary, that in Italy, notwithstanding he was daily exposed to the powerful sun of Rome, in the month of June, the disease, though it began earlier, was nevertheless considerably milder, and also of shorter duration, than elsewhere.

"Most of the internal remedies mentioned by Dr. Bostock,<sup>a</sup> have been tried; but in vain. Bathing in salt water, both cold and tepid, has been had recourse to. The former is apparently without effect; the latter has seemed serviceable only so far as it has relieved the tightness of the chest, and the difficulty of breathing. Of local remedies, the only one which has proved of any efficacy, is the Unguentum Hydrargyri Nitratis, properly diluted. This, though it occasions considerable pain when applied to the eye-lids, has always greatly allayed the itching and smarting; and has even seemed (probably by being carried into the nostrils with the tears) to diminish the irritability of the Schneiderian membrane, and hence to lessen the violence of the sneezing;—a most distressing symptom. The Vinum Opii was tried, many years ago, without any benefit; as in the case of Dr. Bostock.<sup>b</sup>

"With respect to a residence at the sea-side, it may be observed, that the only instance of the disease attacking the patient previously to the usual period, was in the last week of May, 1829, during hot weather;—while he was residing, for a few days, in an airy house, situated on a cliff overhanging the German ocean. The attack, however, was slight, and lasted for two days only; but again returned at its usual period in June. As to diet, the patient is decidedly worse when living low.

"The above detail was written some months ago, and I am happy to state, that the patient almost entirely escaped the disease this year [1831];—by merely commencing, some time previously to the expected period of attack, to anoint the eye-lids at bed-time with the ointment; and by bathing them occasionally, during the day, with a collyrium composed of rose-water and acetate of zinc; and, after this had dried, smearing them with simple spermaceti-ointment;—to remove the stiffness left by the collyrium.

"I have only heard of one example of this curious disease, in this neighbourhood.<sup>c</sup> The patient is a gentleman of fortune; and the instant he approaches a hay-field, he is attacked. I have never been able to hear of the disease in the lower walks of life; though my situation, as physician to two extensive charities in this town,<sup>d</sup> has afforded me ample opportunities of meeting with it, did it exist among them. I may add, that none of the patient's family,—that is to say, neither his father, mother, brothers, nor sisters, though originally amounting to thirteen,—were ever affected in the slightest way by this distressing complaint."

*Mr. Poyser's Case of Hay-Asthma.*—There is another case, with which I have been favoured by Mr. Poyser, of Wirksworth:—"Mrs. H., of middle age, of a full and rather corpulent habit, has been subject for many years to this periodical com-

<sup>a</sup> "Medico-Chirurgical Transactions;" Volume 14; Page 445.

<sup>b</sup> "Medico-Chirurgical Transactions;" Volume 14; Page 446.

<sup>c</sup> Newcastle-upon-Tyne.

<sup>d</sup> The "Newcastle-upon-Tyne Infirmary," and the "Newcastle-upon-Tyne Dispensary."

plaint. 'The attack generally commences about the middle of June,'—the old time, "sooner or later; according to the heat or closeness of the weather. A sensation of heat and irritation is first experienced in the eyes and nostrils; accompanied with sneezing, fever, and restlessness. These symptoms (if the complaint increase) are succeeded by a sense of constriction about the chest; aggravated very much by exertion; and increasing, towards night, to a regular asthmatic paroxysm. In the severer attacks of the complaint, there is a permanent wheezing and difficulty of breathing; with an inability of moving, or of remaining in a recumbent position; and accompanied by pain, fever, quick pulse, and a great degree of general indisposition; lasting for some weeks; and leaving great debility, with an œdematous state of the feet, ankles, &c. The treatment has been conducted on general principles."

'To show the hereditary nature of this affection, I will introduce another extract from Mr. Poyser's letter:—"Mrs. P. A., also the mother of a large family, has had this complaint several years. The symptoms, in her case, resemble very accurately those described by Dr. Bostock;<sup>a</sup> namely, a sensation of heat and fulness in the eyes, accompanied with redness and discharge of tears. These sensations go on increasing; and a fulness in the head is experienced, with irritation of the nose and violent sneezing. To the sneezings are added a farther sensation of tightness of the chest, and difficulty of breathing; with a general irritation of the fauces and trachea. These symptoms are worse by paroxysms, and are often traced to changes of the weather and other causes; they do not, however, as in the instance of Mrs. H., go on to regular asthma. The complaint wears itself out toward the middle of July. This lady decidedly considers the cause of her complaint to be an emanation from the flowers of grass. It begins when grass comes into flower. There is a perceptible increase, or paroxysm, when she is exposed to these effluvia; and when the flowering time is over, she can go into a hay-field with impunity; which she could not previously do.

"The father of this lady is immediately seized with violent and continual sneezing, and inflammation of the nose and eyes, when he goes into or approaches a hay-field; but the symptoms go off when he is removed from the smell of the hay. He therefore carefully avoids the exciting cause, and escapes the disease. Three of the sons of Mrs. A. are also subject to this disease; and their symptoms are similar to hers, though less severe. One of these young gentlemen is now at Geneva; and had the complaint there this summer [1831]. A younger son (a boy about ten years old) is made asthmatic by the smell of Guinea-pigs."

We see, therefore, what the character of this complaint is;—that it is not merely spasmodic asthma, but excessive irritation of the mucous membrane of the eyes, nose, and the whole of the air-passages. It is a combination of catarrh and asthma.

I have no doubt whatever, that it arises from vegetable matter diffused in the atmosphere; that it is derived from the flowers of some plants; and that, in a great number of instances, it comes from grass. The lady to whom I have referred,<sup>b</sup> wrote me a letter, in which she details the whole particulars of her case; and, as it contains many interesting facts, I subjoin it:—"I was first affected with the disease in 1798; and from that period have annually suffered from it more or less. It usually attacks me about the latter end of May, and continues till the middle of July, and sometimes till the close of that month; but this has occurred when the weather has been unfavourable, and the hay-harvest has been particularly late. I have never suffered after the hay has been got in.

"The first symptoms are irritation of the nose, violent sneezing, and all the usual attendants of 'a cold in the head.' These are succeeded by spasms affecting the breath; which have often been so severe as to threaten my life, and are the most distressing part of the disease. Violent irritation of the eyes, throat, and the whole

<sup>a</sup> "Medico-Chirurgical Transactions," Volume 14; Page 437.

<sup>b</sup> See Page 771.

interior of the head, has been experienced when passing by fields where hay was making; which symptoms have all disappeared very soon after entering a room, and excluding as much as possible the external air.

"I believe the complaint with me to arise principally, if not entirely, from the farina of the grass. It has commenced sooner or later according to the season; and my first symptom has generally occurred when walking in the fields, and not till grass is *in flower*; and from that time till the hay-harvest is completely finished, I suffer whenever I am exposed to the air.

"I have tried the sea-air, and also London. The former I found most beneficial; although the latter was productive of considerable relief. Ramsgate and Harwich have suited me best; which I attribute to the small quantity of grass grown in the neighbourhood; and to the bracing air, which has invigorated my general health. At all places by the sea, I have been immediately sensible when a land-wind blew, and felt instant relief when it came off the sea again; and two years ago, when this was the case at Harwich, during nearly the whole of the six weeks I spent there, I suffered scarcely any inconvenience. I walked out daily; went frequently on the water; and bathed regularly in the sea. During other seasons, I have been obliged to shut myself up entirely in the house; and not to allow a window to be opened, or to permit any one who had been into the air to come near me.

"My children, in approaching me after being in the hay-field have often brought on a fit of sneezing, or a spasm of my breath; and this was once effected by their sitting down by me to tea, after playing in the barn where the new made hay was stacked, some time after the season was over. Once, at Harwich, when walking on the shore, I became suddenly affected; which occasioned some surprise, as no grass was apparently near; but, on the following day, I found that hay had been making on the top of the cliff, at the time I was walking under it.

"At Cromer, two years since [1829], I was suddenly seized with shortness of breath, &c., after the complaint had subsided, and all the hay in the immediate neighbourhood finished; and upon going into my bed-room, I saw an immense stack making, in a yard near the house, with hay which had been brought there from a field five miles distant. In 1817, I was perfectly well till the grass was cut in our own fields; when my breath became so seriously affected, that it was thought necessary to remove me directly from the infected air; and I was with difficulty taken from my bed to the carriage which was to convey me to Harwich, twenty miles distant: but when I arrived there, I was so much relieved by the change of atmosphere, that I walked with ease up two pair of stairs to bed; and had no return of illness that season.

"In packing baskets with hay, I have frequently had fits of sneezing, and tingling in my hands; and have every reason to believe, that the seeds of the grass are poisonous to me. I have long ceased to have medical advice for the complaint; and, by avoiding the exciting cause as much as possible, and using palliatives on the first attack, I have of late years suffered less than formerly. I always confine myself entirely, while the hay is making near me; and at other times I walk with salts, or some other pungent scent, in my hand. When I feel the irritation commencing, if I snuff it up, I can frequently keep off a fit of sneezing. My breath is relieved by sedatives; and smoking stramonium will always check the asthmatic spasms.

"My uncle (Mr. \* \* \* \*, of \* \* \* \*) and his son, were affected about the same time as myself;—the former with sneezing only, and the latter with all the symptoms. They both attribute it to the grass; and the son is obliged to come to London when his hay is making. A cold season suits me best, and the symptoms are aggravated by a close air; which may perhaps arise from the obnoxious particles hanging in the air, and being thus inhaled in larger quantities. I have no disposition to asthma at any other period of the year; and scarcely ever have a cold, or occasion to use a pocket-handkerchief. My habit is relaxed; and I am always benefited by a cold bracing atmosphere. I have occasionally found my breath

considerably relieved by going out of the air, into a crowded assembly; and from our own house in the country, to one in a narrow street in the middle of a town."

The disease has certainly increased rapidly during the last twelve years; and has attacked persons of all ages. Most of those with whom I have conversed on the subject, believe it to be occasioned by the farina of the grass, or something poisonous to them, which floats in the air at that time; and which comes when the grass begins to flower, and departs when the hay-harvest is over. It is conceived, by some persons, that it is the sweet-scented grass which is productive of this affection; at least, many persons have decidedly been affected when they have gone near sweet-scented grass in flower; and some ascribe the greater prevalence of the disease now than formerly, and consequently the notice of its occurrence, to the introduction of some new species of grass into this country.

*Treatment of Hay-Asthma.*—Seeing that the emanations from the grass (the pollen, in all probability) is a compound, though I do not know its constitution, I fancied that it might be destroyed by the chlorides;—in the same way as some animal matter. I therefore requested a gentleman who had the disease to try it; and he did so with the most perfect success. This was the first case that I ever saw of the disease. A gentleman came to consult me upon it, about three years before I saw the lady. I told him, at once, that I knew nothing of the affection; and sent him away as he came;—so that neither he nor I got any thing by the interview. I told him that I had heard of such a thing as hay-fever, existing among distinguished lords and ladies, but I could not conceive what it meant, and therefore I could give him no advice. I casually met him, after I had read Dr. Bostock's paper;<sup>a</sup>—and I requested him, as a favour to myself, to try the effect of a solution of chloride of lime or of soda. I directed him to place it in saucers about the bedroom; to have rags dipped in it and hung upon the backs of chairs; to wash his hands and face with it, night and morning; and to carry a small bottle of it with him; and to smell it repeatedly in the course of the day. He complied with my request; and the result was highly satisfactory. The irritation of the ears, (for in his case *they* also were affected,) the tingling and smarting of the eyes and nose, all ceased; and by using this precaution, he got through the summer exceedingly well. Whether the chloride acted by destroying the emanations, or by lessening the irritability of the mucous membrane, or of the skin, I do not know. The chlorides, if well diluted, diminish the morbid irritability of the surface; and therefore they might, in this case, have acted in that way. The treatment, however, was perfectly successful. The lady<sup>b</sup> said that she had used every thing, but in vain; and I could not prevail upon her to try the remedy.

In consequence of making this known in the clinical lecture to which I before referred,<sup>c</sup> it is said by Dr. Poyser,<sup>d</sup> that one of the sons of the lady affected with the disease,<sup>d</sup> employed the chloride of soda. Mr. Poyser says,—“The chloride of soda has been of great use to this gentleman; removing, at once, the sensibility of the nostrils and eyes; and thus allaying the sneezing, cough, and inflamed and watery state of the eyes.” But he adds,—“Mrs. P. A.<sup>d</sup> has not experienced any perceptible advantage from the chloride.” Three out of four, however, did. When persons are also subject to spasmodic asthma, I should recommend them to breathe through water impregnated with the chloride; and a larger quantity ought then to be employed about the bed-rooms, than when they have hay-fever alone.

*Ipecacuanha a Cause of Asthma.*—Some persons are peculiarly affected by other substances. Many persons have a peculiar susceptibility of ipecacuanha;—this is by no means uncommon. If ipecacuanha be powdering in a chemist's house, some persons will be seized with a violent paroxysm on entering it. I have known an instance or two of this description. I heard a physician say that there was a case related on which he could depend,—though I would not myself vouch for its accuracy,—of a person who had such a susceptibility of ipecacuanha, that

<sup>a</sup> See Page 771.

<sup>c</sup> See Page 772.

<sup>b</sup> See Pages 771 and 776.

<sup>d</sup> See Page 774.

on entering a room and being seized with asthma, he declared that there was ipecacuanha about. It was at first denied; but at last some one recollected that there was a box of ipecacuanha-lozenges in a table-drawer. That was going very far; but it is a fact that some persons are seized with asthma, if ipecacuanha be near them.

*The Smell of Different Animals.*—As I shall not have another opportunity of doing it, I may mention here, that other persons are peculiarly susceptible of various things. Some are affected by the emanations of an animal. Shakspeare alludes to some men who cannot bear a gaping<sup>a</sup> pig;<sup>b</sup> and some cannot bear a cat;—they are made miserable if a cat be near them. It does not produce asthma; but the emanation from a cat has such an effect upon them, that they are quite wretched. Mr. Poyser (as I mentioned<sup>c</sup>) states, that the son of a lady who had hay-asthma, is made asthmatic by the smell of guinea-pigs. When he is in a room where they are, he is immediately seized with difficulty of breathing. I have a note from a gentleman, in which he informs me that a nobleman with whom he is acquainted, is affected by sneezing and asthmatic affections, by coming in contact with a hare, or rather the *fur* of a hare; and remains ill for several days afterwards. He experiences great suffering, whether the hare be dead or alive.

*Dr. King's Cases.*—I have another letter on the subject of hay-asthma,—from Brighton; but I will only give a portion of it. Dr. King says:—"I know a member of parliament, who has come to Brighton every summer for some years, in order to avoid the disease at home. A lady also comes from Clapham, for the same purpose; and with the same good effect. The lady, however, whom I saw with it, told me that she knew a cobbler's wife who had it; and that several persons of the lower orders, to her knowledge, had the disease. Last year [1830] I met, at Lewes, a farmer's wife, subject to the same complaint; and obliged, every hay-season, to take refuge in a town. She bears up against it as long as possible; and shuts herself close up in her room, till a sense of suffocation comes on,—as in common asthma; when she is obliged to throw open the window, by which a fresh dose of poison is let in; and the same routine is gone over again, till she is obliged to fly. On quitting the regions of hay, she experiences immediate relief. I dined lately in company with a lady, who went into convulsions as soon as her plate was put before her;—owing to its containing some peas which had been boiled or dressed with mint. We carried her out of the room; and she did not feel quite well all the evening. Her daughter, who sat next her, was not similarly affected."

These are circumstances worth knowing; because, if we were not acquainted with them, we might ascribe cases of this description to whim and fancy. It would be very odd if they were confined to the higher orders only. It is a thing exceedingly improbable. The fact is, the lower orders consider the hay-fever as merely a common cold; and they do not apply for medical advice unless they are seriously ill. They do not think of applying to a public charity, because they are seized with a violent sneezing; or if they do, it is a solitary case, and is treated as asthma;—the nature and causes of the disease not being known.

*Cases recorded by Laennec.*—Laennec had no idea of it; but he mentions one or two curious circumstances. The following fact, he says, was communicated to him by one of his colleagues;—as affording a curious instance of nervous affection, in a man not subject to asthma:—"A man, forty years of age,—slightly hypochondriacal, but otherwise in good health,—wished to go on horseback to pay a visit some leagues distant from his house. As soon as he left the town where he resided, which is situated in an extensive plain, he felt an immediate oppression on the chest, from the impression of the country air. He took no notice of this at first; but the dyspnoea having greatly increased, and being now attended by a sense of faintness, he determined to return. He had scarcely turned his horse, when he found himself better; and in a few minutes he recovered both his breath and his strength. Not suspecting any relation between this momentary uneasiness and his

<sup>a</sup> Squeaking.

<sup>b</sup> "Merchant of Venice;" Act 4; Scene 1.

<sup>c</sup> See Page 775.

journey, he once more attempted to advance; and was again soon attacked with the dyspnœa and faintness. On turning towards the town, these passed off. After having made repeated attempts to proceed, and always with the same result, he finally returned; and in just as good health as when he set out. I have lately met," continues Laennec, "with a case very analogous to the one just related; only that in this the symptoms were more severe, and the cause was different. Count H——, a man of robust constitution, and although now eighty-two years of age, still possessed of a degree of vigour unusual even at the age of sixty,—has been subject from his infancy to attacks of asthma; and is habitually somewhat short-breathed. Since his fiftieth year he has had a slight cough; and in the morning a pituitous expectoration, intermixed occasionally with some yellow sputa. The asthmatic attacks have always been unfrequent with him; but they have invariably come on if any person has inadvertently shut his bed-room door, or if his night-lamp has by chance gone out. As soon as either of these accidents occurs, he immediately awakes with a feeling of oppressive suffocation; and after a few minutes he becomes insensible. On the occasions alluded to, the attack is got rid of by opening the doors and windows, lighting the candles, and carrying the patient into the open air. I presume it is the smell of the lamp which causes it; and perhaps the emanations from his own body,—the smell of his own perspiration when he is shut up.

We find, therefore, that in many instances of asthma, there is a violent external exciting cause; but it varies much in its power in different individuals. A predisposing cause, in many persons, is bronchitis; and, in others, various organic diseases of the chest. In some persons, without any external excitement at all,—without moisture, or coldness, or confinement from the air,—there will be an asthmatic paroxysm;—simply from an irritable state of the mucous membrane, and from organic disease. I have already alluded to one case where, from the mechanical pressure of a small aneurism, a paroxysm came on, independently of all external circumstances.\*

*Treatment during the Paroxysm.*—The treatment of this disease may be divided into two parts;—one part relating to the treatment during the fit; and the other to the way of preventing its recurrence. In the fit, if the patient be plethoric, it may be well to bleed; but in general this is not necessary. One of the best things that can be done is to give the patient a full dose of opium. Frequently a very large quantity is borne;—on account of the exceedingly deranged state of the system. Forty, fifty, or sixty drops of laudanum, are frequently not more than sufficient to relieve the fit. I once had an extraordinary case of this kind; where such a dose was given without any effect. A drachm was then given, but still without any effect; and so also were two drachms. Seeing this to be the case, the medical gentleman who was attending the patient, grew out of patience, and gave half an ounce; which was merely sufficient to get rid of the paroxysm. When the next paroxysm came on, however, that dose failed entirely; and six drachms were given, and produced tolerable relief; but not enough, and at last many drachms were given for a dose, with no more effect than that of putting a stop to the paroxysm. These are states of the system in which ordinary doses are of no use; but, in general, from forty to sixty drops are borne very well; and are sufficient. It is useful to combine the laudanum, in these cases, with a dose of æther; and if we mix them up with ammonia, or with musk, or assafoetida, we shall generally add to their good effect. But opium generally answers the purpose. Should the patient be plethoric, however, and have chronic bronchitis and fulness of the chest, it would be very wrong to give a large dose of this description, lest it should produce apoplexy; and it would be right to take away a certain quantity of blood. Some patients are relieved by cupping, and some by dry-cupping.

*Treatment after the Paroxysm.*—When the paroxysm is over, we may endeavour to prevent its return, by giving a dose of some preparation of opium, together

\* See Page 720.

with æther: but in a smaller quantity than in the former case. Some persons have told me, that they have seen very great relief from cantharides, in this complaint and in hooping-cough. Whether they really are beneficial I cannot tell; but the advantage of opium, æther, musk, and assafœtida, is unquestionable. Some have found very great relief from smoking stramonium. I have seen many persons, who have derived benefit from smoking the leaves and stalks of stramonium, chopped up together. Some have found the smoke of *tobacco* serviceable; but far fewer than those who have derived benefit from stramonium. It is of very great use to make patients drink strong coffee, without milk and sugar. It is an old remedy, but a very good one. There ought to be no grounds in it, because they may disturb the stomach; and that organ, in this complaint, is generally much disposed to indigestion. If it should so happen that a paroxysm comes on from a hearty meal, it will be found very serviceable to give a good emetic, either of mustard or sulphate of zinc;—something which will not nauseate the patient long, but will empty the stomach as quickly as possible.

I am supposing, all along, that the patient is free from chronic bronchitis;—has simple pure asthma. If, however, there be any chronic bronchitis present, squills, digitalis, colchicum, and ipecacuanha, will all be useful;—some by increasing the flow of urine, and others by increasing the secretion from the air-passages. Some have found relief from opium and prussic acid, and others from hyoscyamus and conium; but if an immediate effect be desired, I think there is nothing equal to opium and stramonium. There is no rule for these things; for some persons are relieved by *one* article, and some by another. It is right to consider this as a spasmodic disease, which may be removed; and if it can, it should. It may arise from a full stomach; and then an emetic is the best remedy. It may arise from grass; and then the chlorides scattered about the room, I conceive would be the best remedy.<sup>a</sup> But if we cannot remove the exciting cause immediately, or at all, then the best mode of treatment is to employ venesection and opium.

*Prophylactics.*—With regard to the *prevention* of the disease, besides the remedies just mentioned, and besides removing the patient from the exciting cause if it be known, it is of great use to pay attention to the stomach and bowels. Every body knows, that if the abdomen be distended, the diaphragm cannot descend freely, and we can scarcely breathe; and asthmatic people suffer, in these circumstances, to a very great degree. Dr. Wilson Philip has spoken highly of galvanism in this complaint, and no doubt it does good; but we cannot expect it to be universally efficacious, when we consider that asthma is often united with organic affections, and with chronic bronchitis. When persons are very weak, tonics are necessary,—particularly iron. Dr. Bree used to exhibit the sesquioxide of iron particularly in the disease;<sup>b</sup> but I have not found it useful, except as a *tonic*. With regard to the inhalation of chlorine, it may be had recourse to in every form of asthma. We may impregnate water with it, and make the patient breathe through it, and in that way inhale it. The same means may be adopted with regard to prussic acid and conium. Some have found benefit from tar; and others from tanners' liquid, put in one corner of the room. Another way of giving persons the advantage of these things, is to impregnate water with them; and to make patients breathe through the water, three or four times a day.

## SECTION II.—HOOPING-COUGH.

*Synonymes.*—The next disease which I shall describe, and which (in some respects) is very much allied to the last, is hooping-cough. The disease is so called, from the peculiar noise attendant upon the cough. Sometimes it is called "*chin-cough*," because it particularly attacks children; and "*chin*" (I suppose a

<sup>a</sup> See Page 777.

<sup>b</sup> "Practical Inquiry on Disordered Respiration; distinguishing Convulsive Asthma, its Specific Causes, &c. By Robert Bree, M.D."

corruption for "*kind*") is the German for "*child*." In Latin it is called "tussis,"—"cough;" or, to show its intensity, "pertussis,"—"much cough."

*Symptoms.*—This disease is easily known when it has been once seen. There are occasional fits of violent coughing, with short expirations,—a volley of them; and then one deep, long, hooping, crowing inspiration; and these are many times repeated. A quantity of viscid phlegm is spit up; and very often the child vomits. The cough is exceedingly severe; every muscle is put into action; the face grows red; the eyes "run;" and then the child, although unable to stand, and apparently about to be strangled, runs about and plays an instant afterwards, as if nothing were the matter with him. This is very commonly seen: and the cough will come on day after day. At first, there is generally some catarrh and bronchitis with it; and these are of various intensity, as is also the cough. Sometimes the bronchitis is very considerable; so that the child has a constant difficulty of breathing, a constantly quick pulse, and constant heat; and is exceedingly ill. The disease, although to a great degree spasmodic, and sometimes almost entirely so, is occasionally, on the other hand, inflammatory in a high degree. When it has been inflammatory, and the child recovers, the spasmodic cough will frequently continue, even for months after the inflammatory state has subsided.

*Premonitory Symptoms.*—The first notice of the disease, is generally occasioned by the extreme violence of the cough, or by a hoop. Very frequently it is not noticed at all, till the child hoops; and then there is no doubt of the nature of the disease. In fact, we are never justified in saying that the disease exists, till the child hoops. If the disease prevails in the neighbourhood, and the child coughs more violently than usual, in all probability, it will "turn" (as people say) to the hooping-cough. But if the disease be not fully formed, one cannot say with certainty that it is the disease, unless the child hoops.

*Duration and Prognosis.*—If the bronchitis be violent, or if it continue for a great length of time, though not violently, the child may die. As a mere spasmodic affection, hooping-cough does not generally destroy life. In the greater number of cases where children die, there is a violent or extensive bronchitis, and a violent or extensive inflammation of the substance of the lungs.

The disease may destroy a child in two or three weeks, or it may not destroy it for many weeks; but after the disease has lasted six or eight weeks, it generally gives way. It seldom continues longer. Children, however, from the very slightest cold, are apt to hoop again. Some will hoop occasionally during the greater part of a twelvemonth; and some, when they have once had the disease, will be observed to hoop at a more distant period even than that, if they catch a severe cold.

When a child vomits, it is generally considered a good sign. If there be no vomiting with the cough, it is observed by those who have most experience, that the child gets worse. Dr. Gregory knew a lady, who never hooped in the disease; and therefore it was hardly "*hooping-cough*." The disease prevailed in the family, and she had as violent a cough as the rest; but at the time she ought to have hooped, she always *fainted*.

The danger is in proportion to the other symptoms;—that is to say, the symptoms of affection of the head, and of bronchitis and peripneumonia. The younger the child, the greater the danger. It is a very dangerous disease when it occurs in infants. Those who suppose that the disease arises from contagion, consider that it remains latent, from a few days to a few weeks; and they suppose that the disease itself, when it occurs in an individual, is not capable of communicating contagion beyond a month or six weeks;—just as is the case with other contagious diseases. Gonorrhœa, for example, after a certain lapse of time,—although nobody will venture to fix the period,—is not contagious.

*Morbid Appearances.*—On opening children who have died of this disease, we occasionally find very little the matter in the lungs. The child may have died from something else; for the disease has a great tendency to produce hydrocephalus, convulsions and various affections of the head;—such affections as we see in

children.<sup>a</sup> It is one of the great calamities attending the disease, that the effects of it are so fatal. There is such continued difficulty of breathing, and such violent cough, that the vessels of the head are over-distended; and the consequence is such congestion and irritation of the head, that hydrocephalus continually occurs. I know that violent coughing will overstrain the vessels of the head, and produce great mischief; for I saw an infant that had never been well from the moment it had coughed violently. It was so strained, that the parents (from time to time) fancied it would die. From the instant of the coughing, the head drooped, and convulsions came on; of which it ultimately died; although, till seized with this violent cough, it was comparatively well,—having nothing the matter with the head; and having only a common cough at first;—such as other children in the family had. Thus children die from hooping-cough; or from the *effects* of it, rather than from the disease itself; and yet, after death, we can discover very little wrong in the lungs. But frequently, indeed *generally*, on examining the lungs, we find a large quantity of mucus in the bronchia. The mucous membrane is red, soft, pulpy, and increased in thickness; so that there is clearly bronchitis. Frequently, also, the lungs are very solid. The air-cells have become inflamed; and the lungs are very much hepatized. I have opened children who have died from hooping-cough; and nearly the whole of the lungs have been like liver. They did not collapse; and, on pressing them, we could scarcely diminish their bulk in the least. When bronchitis takes place, on listening to the chest, the common signs of that disease are found to be present;—there is the sonorous rattle which occurs in the breathing of adults; and we hear the respiratory murmur excessively loud and rough throughout the chest,

*Causes.*—By far the most frequently it affects *children*; but it also affects *adults*. I heard that the late Archbishop of Canterbury<sup>b</sup> had it, a short time before he died. It is frequently an epidemic disease. It does not, in general, occur more than once; except in a mere spasmodic form;—when the parts are thrown into such a condition as to produce hooping, although the real disease does not return. Hooping-cough is supposed, by some, to depend on a specific contagion. Some deny this; but others assert it. I was always taught that this was its source, and I never thought of doubting it; but others have done so, and I suppose they have a reason for it. Any irritation whatever will provoke a paroxysm, when a patient has the disease. If a child be put in a passion, or we move it about quickly, or give it any thing stimulating, then a paroxysm will take place. There may be various exciting causes of a *paroxysm*; although the peculiar exciting cause of the *disease*, I presume, is only one;—either a specific contagion, or something peculiar.

*Pathology.*—[There has been great diversity of opinion respecting the nature and essential seat of pertussis. Cullen, Guibert, Hoffmann, Hufeland, and most other German authors, consider the disease as essentially nervous;—depending on irritation (not inflammation) of various parts of the nervous system, particularly the phrenic and pneumogastric nerves; and causing spasmodic action of the larynx, diaphragm, and stomach. Leroi, Webster, and Begin, ascribe the disease to inflammatory irritation of the brain and its membranes. Watt, Badham, Dawson, Dewees, Guersent, Laennec, and most other French authors, hold the disease to be essentially bronchitic or catarrhal, with the addition of convulsive action of the

<sup>a</sup> I (Dr. Elliotson) was suddenly called to an infant in convulsions, which had begun some hours before. It had been labouring most severely under hooping-cough for a month. I instantly took away a large quantity of blood from the head by leeches, but was too late; the convulsions, insensibility, squinting, &c., never ceased; and the child died in two hours. On cutting into the brain, innumerable large orifices of blood-vessels appeared, and the arachnoid membrane of the ventricles was a uniform scarlet tissue of vessels. Although the hooping-cough was violent to nearly the last hour, the lungs and trachea were perfectly free from the smallest mark of inflammation or any other disease; a little mucus only was found in the ramifications of the bronchia. This case explains why prussic acid is so generally serviceable in hooping-cough. Convulsions are a common effect of hooping-cough, and here arose from it as a disease purely spasmodic.

<sup>b</sup> The Rev. Dr. Manners Sutton.

diaphragm and larynx; excited, according to some, by an excessive sensibility of the inflamed bronchial membrane. A third view, particularly maintained by Desruelles, is that whooping-cough depends on inflammation of the bronchi, speedily causing irritation in the brain; whence is reflected convulsive excitement of the diaphragm, muscles of the larynx, &c.; which gives to the cough its peculiar character. Dr. Copland<sup>a</sup> considers the disease to be essentially a nervous irritation; commencing in the respiratory surfaces, and (through the nerves, chiefly the pneumogastric) transferred to the "medulla oblongata;" whence it again affects the respiratory apparatus, and sometimes the stomach; and that predisposing or concurrent causes may readily convert this irritation, at either of its seats, into inflammation.

In reference to these different views we<sup>b</sup> may remark, that in many instances they do not sufficiently regard the physiological character of those morbid motions, which form the chief feature of whooping-cough. Thus we find much ascribed to the phrenic nerve and diaphragm; when it is obvious that these agents of inspiration are little, if at all, concerned in the motions which constitute the cough. We<sup>b</sup> regard whooping-cough as originating in a specific irritation (almost always inflammatory at first) of the lining membrane of the upper portions of the air-passages. This irritation is in the first stage constant, and accompanied with cough and expectoration, like those of common inflammatory catarrh; but in the second stage it peculiarly increases the irritability of the laryngeal constrictor and bronchial muscles; and of the nerves which excite the contractions of these, as well as of the expiratory muscles which are sympathetically associated with them;—those, in fact, which are concerned in the act of coughing. The peculiar cough of pertussis resembles that excited by a foreign body directly irritating the glottis; in fact, it is properly called "*pertussis*;" for it consists of an exaggeration of all the actions of an ordinary cough, and of nothing more; and there is no more reason for seeking its cause in the brain or spinal marrow, than there is for referring excessive vomiting or dysenteric straining to this seat. It is unnecessary to go further than the respiratory apparatus, for an explanation of the phenomena of whooping-cough. The irritation which at first extends to the vessels and is more constant, becomes afterwards purely nervous; and, like other local nervous affections,—such as neuralgia, spasms, nervous colic, &c.,—manifests its effects only occasionally, perhaps under the influence of some additional exciting cause. The various complications which so much increase the danger of whooping-cough, we would regard chiefly as the effects of the violent cough; sometimes assisted by predispositions to particular diseases, or by co-operating causes. Any one who has witnessed the severe paroxysms of whooping-cough, can scarcely wonder that it may produce in the head, in the lungs, and in the abdomen, serious congestions: which previous tendencies, or additional exciting causes, may readily convert into inflammation and its effects; hydrocephalus, pneumonia, and intestinal disease.<sup>c]</sup>

*Treatment of the Inflammatory Stage.*—The treatment of whooping-cough is twofold;—accordingly as it respects the *inflammatory* or the *spasmodic* condition of the parts. The most important thing, by far, is to remedy the inflammatory state;—the bronchitis or peripneumonia. If it be found that there is a constant oppression of the breathing, with spasmodic attacks of increased difficulty, and occasionally a violent cough, and that there is an accelerated pulse, and pyrexia, together with sonorous, sibilous, and crepitous rattle,—it will be evident that there is inflammation of the bronchia, or the substance of the lungs;—the air-tubes, or the air-cells, or both. Of course that inflammation must be remedied in the usual way. We might give all the antispasmodics, all the narcotics, and all the other medicines that are supposed to have a direct influence over the spasm, and yet do no good. In fact, we should make the patient worse; and if nature were not to get the better of us, and cure the individual, there is every probability that great mischief would

<sup>a</sup> "Dictionary of Practical Medicine;" Volume 2; Page 242.

<sup>b</sup> Dr. C. J. B. Williams.

<sup>c</sup> "Library of Medicine;" Volume 3; Pages 97 and 98.

be done. It is therefore highly important to ascertain the existence of inflammation; and to remedy it, if possible, in the usual way;—by taking blood from the neighbourhood of the chest; occasionally by bleeding in the arm, if the patient be old enough; but particularly by *local* bleeding, and the exhibition of mercury, and of emetics.

*Emetics and Leeches.*—In the greater number of cases, the inflammation is such as will yield to the application of a few leeches, and the exhibition of emetics; but it is of great use, at the same time, to clear out the bowels by calomel,—provided the inflammation is severe; and to give it steadily in small and repeated doses. The inflammation is frequently not so severe, but that an emetic every day, or night and morning, will be found sufficient for all the purposes of remedying the bronchitis; still I would not trust to it in severe cases.

In this, as in most diseases of children, the warm-bath is of essential service. It is thought by some, that the friction of tartar emetic ointment over the chest, is more useful than the application of blisters. I rather feel disposed to think that this is the case; and that blisters are not of very great utility in the affection.

*Regulate the Diet.*—It is of great importance not to allow children to overload the stomach; for the cough is generally much more troublesome after meals than before. When there is any inflammation, the food should (of course) be exceedingly light;—affording scarcely any nourishment; and the patient should not be allowed to distend the stomach with liquids. During the whole period of the disease, even when the inflammation is gone, the food which is given should be very compendious,—not bulky. It is also of great use, in this disease, to prevent children from moving about a great deal; for running will frequently excite the cough; and it is also of great use to keep the child quiet mentally; for a fit of passion will bring on a violent cough. The bronchitis will sometimes continue for a great length of time. The breathing will be difficult for some weeks; there will be more or less feverishness; and the child will waste away; but by the steady employment of antiphlogistic regimen, with a moderately open state of the bowels, many cases will do exceedingly well;—notwithstanding the bronchitis may continue, though not in a violent degree, for some time.

*Treatment of the Spasmodic Stage.*—Next to the employment of emetics, narcotics are of very considerable use. Emetics will not cure the disease; because there is, in many cases, violent inflammation, and we must treat that in the usual way; but there is hardly a case of hooping-cough, that will not be much mitigated by the continued use of emetics. In the first instance, a large number of cases may be trusted to them, and to the administration of narcotics. Prussic acid is very useful in this complaint; not in subduing inflammation, but in subduing the tendency to cough. We may give it to the youngest child; but of course it should be in a small quantity. If the child be young, we may put one minim to one or two ounces of almond-emulsion; and one tea spoonful of this mixture will sometimes be found as much as is proper. This is one of the most convenient modes of exhibiting it; and from the sixteenth to the fourth of a minim may be given, three or four times a day. After the disease has lasted some time, opium is more or less useful, given in a small quantity. “Dover’s powder” is one of the best forms. The extract of conium and hyoscyamus may be given in small doses, rubbed up in mixtures or emulsions; but I think prussic acid is one of the best things. It will not cure the disease; it has no specific power over it, any more than any other narcotic; but it does remedy spasmodic irritation of the air-passages, exceedingly well; and very often better than other narcotics.

*Tonics.*—After a certain time has elapsed, and no bronchitis exists, or so slight a degree of it that it requires no inflammatory treatment,—when there is debility and irritation of the air-passages, rather than any thing else,—tonics may be given. Various *metallic* tonics have frequently been employed. I do not know that any one is so good as iron; it seems to me to be the best we have. The sulphate is a form in which the medicine may be given to children very conveniently, dissolved in various mixtures; and, as they are fond of sweet things, the sesquioxide mixed

with treacle, may be very easily given them. I am not aware that it exerts a particular power over the cough; but, when the disease has existed some time, such remedies are very useful.

*Friction.*—Some persons place great reliance upon friction, with some external application; and narcotics are frequently applied in this way. I believe that a very good remedy is a quack medicine, called “Roche’s Embrocation.” Any stimulant not sufficient to abrade the cuticle, and produce inflammation, if it have united with it a quantity of opium, will be found exceedingly serviceable. Friction along the spine is particularly recommended.

*Cold-Bath and Change of Air.*—After a time, there can be no doubt of the use of the cold shower-bath; but one of the best things is change of air. Every old woman says so; and I believe she is perfectly right. I have known (as every one must) many cases, where the cough continued in spite of all the medicines that could be given, and all the physicians that could prescribe them, till the residence was changed; and then the cough speedily diminished. This will not do good at the beginning. It is only when the disease has existed some time, and is disposed to cease, that a change of air will cause it to disappear, better than any thing else.

*Inhalation of Tar or Chlorine.*—The inhalation of tar-fumes has been recommended; but as these are acrid, it would be a wrong practice during the inflammatory stage; though when the disease becomes merely spasmodic, they may be of use. The mode of employing the tar, is to put it in a pipkin in the room, and to let the fumes ascend so as to impregnate the air. In doing this, great care should be taken that the fumes are not too strong; or they will *cause* irritation, instead of *subduing* it; but, with proper precautions, it is a remedy that is of great use. I dare say chlorine, used about the room in the same way, would be beneficial; but great care is required not to use these things to the degree of producing irritation.

Hooping-cough is a very troublesome disease to treat. We may save life by subduing inflammation; but with regard to removing the complaint, we may find ourselves very much baffled. Much good, however, may be done, with respect to the spasmodic part of the affection, by good management;—by giving light food, and a very moderate exhibition of narcotics. Of all these prussic acid is the best; for although its exhibition is not very satisfactory, I am persuaded it is *more* satisfactory than that of any other narcotic.

## CHAPTER X.

### PHTHISIS PULMONALIS.

I SHALL now describe an *organic* disease of the lungs, for which unfortunately we can do little or no good; and which causes more destruction in this country, than any other affection whatever. It is “consumption.” I shall commence by describing, not the symptoms, but the changes of structure which takes place in the lung itself.

*Definition.*—This disease is called, in *common* language, “consumption,” or “*pulmonary* consumption;” and, in *medical* language, “phthisis pulmonalis,” or simply “phthisis;”—“*pulmonalis*” being understood. The word “*phthisis*” is derived from φθω, *to consume*. This disease is apparently of a scrofulous nature. The substance which is deposited is precisely that which takes place in those parts which are said to labour under scrofula. Some have made varieties in phthisis, as being tubercular or not; but by “*phthisis*” is now meant, not an *ulceration* of the lung, but a *scrofulous disease* of the lung; which *may* produce ulceration; and which *will* produce ulceration, if it continue long enough. But ulceration not connected with this disease, is not called “consumption.” An abscess may be formed

from common inflammation, rare as it is; but that is not called "phthisis;"—it would be called simply "an abscess in the lungs," or "a vomica." By "*phthisis*" is meant a deposition of a serofulous substance in the lung; and all the organic changes to which its presence, or the state which produces its presence, gives rise.

## SECTION I.—PATHOLOGY OF PHTHISIS.

*Deposition of Tubercles.*—The deposition, in this disease, takes place in minute granules; which are grayish, semi-transparent, and pretty firm; lying close to each other, over a certain space in the substance of the lungs. Although at first they lie distinct from each other, yet they are close. They increase in size; and they likewise increase in number, and, as they increase in this twofold manner, they of course approximate. The space between them diminishes; till they coalesce, and form a mass. When they increase in size and number, they possess less semi-transparency;—they become opaque and yellow. This change is first observed either at the centre, or on some part of the surface; and from the point at which it commences it gradually pervades the whole "tubercle," as it is called.<sup>a</sup> When the tubercles are few, they seldom exceed the size of an almond each; but the masses produced by their aggregation, may be very large. I have often seen the whole of one lobe of the lung, and I once saw the whole of one lung, converted into a solid tubercular mass. Laennec conceives that, in such a case as this, the tubercular deposition has taken place in a diffused manner;—that there has not been a formation of distinct separate tubercles, but that the substance was diffused in the texture of the lung; and he calls this mode of deposition "tubercular infiltration."<sup>b</sup> Whether he is right or not, I do not pretend to say.

*Their Shape and Situation.*—The shape of the tubercles is round, and rather oval; and this might incline us to suspect, that their situation is the air-cells. That they may be formed within the air-passages, is proved by the dissection of glandered horses by Dupuytren and Andral. The bronchial tubes were filled with granules, mixed with pus and tubercular substance. Hence it is clear that these substances may be found in the air-passages; and Andral says, that he also found a tubercular mass in the minute twigs of the bronchia, where no ulceration existed; of course, therefore, the deposit may be formed in the air-cells. Many have said that this deposition takes place in the cellular membrane of the lungs; but when we consider its situation, and consider that it is found in the minute bronchial twigs, and not leading to ulceration, it is probable that it is formed in the air-cells. Cruveilhier says that, after injecting mercury into the bronchia of a living animal, he found each globule of the metal surrounded by a concrete substance, formed of white granules, in various parts of the lungs. By injecting the mercury into the bronchia, it reached the air-cells; and he afterwards found granules, formed of tubercular substance, around the globules of mercury. Still it is to be remembered, that a similar effect is produced in the cellular membrane, by injecting mercury into an artery; and that flakes, precisely similar to those in the lungs, are seen in the spleen, and in the cellular membrane of various parts. I will not, therefore, take upon myself to pronounce, whether tubercles exist in the one or the other. They may exist in both; but there are arguments on both sides.

*Softening of the Tubercles.*—After a longer or shorter time, the tubercular mass softens,—generally first in the centre: and the greater part becomes a fluid, resembling pus, in the midst of which are seen particles of the original solid and friable deposit. The membrane which is often found around the deposition, likewise secretes pus. Long after the tubercle is gone, the membrane which surrounds it continues to secrete pus; and the cavity enlarges by ulceration. The openings of the bronchia, which had been lost by the deposit surrounding them,

<sup>a</sup> See Page 190.

<sup>b</sup> See Dr. Forbes's Translation of Laennec's Treatise on Diseases of the Chest; Part 1; Book 2; Chapter 7. (Third Edition; Pages 278 and 282.)

blocking them up, compressing them, and causing them to ulcerate,—are seen opening into the cavity of the abscess, on all sides. Bands of pulmonary substance, and blood-vessels (shrunk and obliterated), are seen leading across the cavity. with tubercular deposit upon them; while a great number of blood-vessels are completely obliterated, and run flattened along the sides.

*Usually Commences at the Superior Part of the Lung.*—While some tubercles are advanced to this degree in one part, others are less advanced; and others, again, are exceedingly minute (having been recently formed); both at a distance, and in the neighbourhood. We see them in all states, in the same lung: but it is an established fact that, in by far the majority of instances, the greatest deviations from a healthy structure, exist at the superior part of the lungs; and the first tubercles are, in the greater number of instances, deposited there. The reason why there is the greatest devastation at the upper part of the lung, is because the tubercles are first deposited there. In proportion to the duration of the tubercle, in general, is the change it has undergone; and if tubercles, therefore, be deposited in the upper part first, we may expect the third stage to be arrived at there, sooner than at the other parts. The reason of the tubercles being first deposited in the superior part, is not known; unless it be that the superior part of the chest is more exposed to the vicissitudes of temperature, than other parts. It certainly is a fact, with respect both to males and females, that the upper part of the lungs is less covered by dress than the lower. In ladies, and in women of all ranks, the neck is bare; and so is the upper part of the chest; and with regard to ourselves, we have the breast more open than the lower parts; except when close square waistcoats are worn. But whether this will explain the circumstance I have mentioned, I will not pretend to say.

Some have made observations upon which lung is most affected with tubercles. Laennec says the *right*, but the majority of authors say the *left*; and therefore I suppose that one side is as much subject to them as the other. I have never made any observations on the matter.

[The upper and back part of the lungs is the most common seat of tubercle, and the left side is more frequently affected than the right;—an observation first made by Stark, and corroborated by Carnichael Smyth from an examination of the cases recorded by Bonetus and Morgagni, and more recently by Louis from his own experience. The last author found tubercles exclusively confined to the right side in two cases only, and in five to the left; of thirty-eight in which the upper lobe was totally occupied by large excavations and tubercles, so as to be impermeable to air, he met with twenty-eight in the left and ten only in the right lung; and in eight of perforation of the pleura, he found seven on the left and one only on the right side. When to these observations we add the result of Reynand's experience,—who, of forty cases of pneumothorax, found twenty-seven on the left side, and thirteen only on the right,—I consider that there is sufficient evidence to confirm the conclusion, that the left lung is most frequently affected.<sup>a</sup>]

*State of the Lung around Tubercles.*—The intervening portions of the lung, dividing the tubercular deposition, are not always healthy;—being frequently turgid with blood, and with a bloody serous fluid; and sometimes they are indurated, and of either a red or a gray colour. The bronchial membrane, on being slit up, is frequently found red; and evidently smeared with a far greater quantity of mucus than in health. Thus there is evidently peripneumonia,—inflammation of the substance of the lungs, in many cases; and likewise bronchitis. I think there can be no doubt, that by far the greater quantity of expectoration in phthisis, is derived from the bronchial membrane;—much more than from the abscess; and the fluid secreted by the bronchial membrane is, as in common bronchitis, of all degrees of consistency, and of all degrees of quality.

*Dr. Stark's Researches on Phthisis.*—Admirably as the morbid anatomy of phthisis has been investigated by the French, I am bound to do justice, on this

<sup>a</sup> "A Treatise on Pulmonary Consumption. By Sir James Clarke, Bart, M. D." Pages 128 and 129.

subject, to one of our own countrymen; as I formerly did<sup>a</sup> on the subject of the enlargement of the air-cells, to Sir John Flower, and Dr. Baillie,—a truly eminent physician of the last generation. In the “Medical Communications,”<sup>b</sup> there is a very admirable paper on the Morbid Anatomy of Phthisis, by Dr. Stark; who was a very clever young man, and fell a victim to his ardour in investigating Morbid Anatomy. Dr. Stark, more than fifty years ago,<sup>c</sup> pointed out that phthisis was essentially a tubercular affection;—a fact which, though known to Hippocrates, had been passed over by almost every other ancient writer;—Greek, Roman, and Arabian; and by many of the moderns. Sydenham himself considered tubercles and abscess, as rather the *effect* of disease, than the actual disease itself. Boerhaave was not acquainted with the subject. Dr. Stark, in his paper, traced the tubercles from their original minuteness and solidity, to their enlarged and softened state. He asserted that the chief seat of the affection, was the superior and posterior part of the lungs; and particularly, he says, the *left* lung;—agreeing therefore with a great number of writers, in opposition to Laennec.<sup>d</sup> He stated that the bronchial ramifications were never obstructed or obliterated, but opened into the cavity; but that the blood-vessels suddenly became constricted near the orifice; and even obstructed by a coagulum; so that an injection would not pass into the abscess from the large blood-vessels, or flow into the blood-vessels around the abscess. He found that the injection rendered the surrounding parts quite hard; so that the diseased parts which appeared firm before, became soft by contrast. He also mentioned, that the parts unaffected by the tubercles, but immediately around them, are generally red and firm; so that he found, between the effects of the tubercles and this induration, that about one quarter only of the lungs, in extreme cases of phthisis, remained fit for duty. He ascertained that the tubercles generally have a capsule; and that adhesions of the costal and pulmonary pleura, generally exist where an abscess is within. We find, on opening persons who have died of phthisis, and when the tubercles exist near the surface,—especially if they be softened down,—that there are adhesions on the outside of the surface of the lung, attaching it to the pleura. This is a provision of nature, to prevent the escape of the contents of the abscess into the cavity of the membrane. The care taken by nature to prevent sudden and speedy death,—which would take place, if the blood-vessels were not filled up by a coagulum, and flattened down upon the sides; and the equal care taken to prevent sudden death from inflammation of the pleura, occasioned by the escape of pus from any of these abscesses,—is certainly very striking; but both circumstances were pointed out long ago by Dr. Stark. The French are not aware of his existence; having, till of late, read but little of English literature.

## SECTION II.—SYMPTOMS AND PROGRESS OF PHTHISIS.

The symptoms of phthisis vary, according to the progression of the tubercles. This is the case both with the general symptoms, and with those which are to be learned by the ear. When the tubercles are only in a solid state, and are not united together into groups, we can learn nothing of their existence from the ear. We can only *presume* their existence, from the general state of the patient; and therefore cannot be *sure* that tubercles are formed. When they are sufficiently numerous to constitute groups, then, on striking that part of the chest, we hear a different sound from that which is audible, when nothing but air is present. When the part is softened, and a cavity is produced, various other sounds will be heard. The part will sound different from what it would, were there no cavity at all, and no unnatural state of the parts; but where the air enters a healthy part, and leaves

<sup>a</sup> See Page 750.

<sup>b</sup> “Medical Communications, by a Society for the Promotion of Medical Knowledge.”

<sup>c</sup> In 1788.

<sup>d</sup> See Page 787.

it again. From what I have said respecting the morbid anatomy,<sup>a</sup> the cause of the different symptoms I have to detail will be evident. There must necessarily be more or less pain, cough, expectoration, and at last hectic; and we shall see that the sounds in the chest must all perfectly correspond.

*General Symptoms: Hæmoptysis.*—This is, for the most part, a very slow and insidious affection. Long before any other symptom occurs, it is very common for the individual to be seized with hæmoptysis,—“spitting of blood.” This, as I mentioned when speaking of hæmoptysis (or “hæmoptoe,”<sup>c</sup> as it is sometimes called), is usually from the bronchial membrane.<sup>c</sup> The blood is of course frothy, scarlet, and mixed with air. Occasionally it is in considerable quantities; but, for the most part, it is not to any great amount. The patient frequently has several returns of this, before any other particular symptom of phthisis presents itself. When phthisis occurs, there is then, for the most part, little or no more spitting of blood.

*Cough.*—Whether this has occurred previously or not, one of the first symptoms noticed is a short tickling cough;—such a cough as the patient denies even to exist. It is observed by his friends, while he himself for the most part complains little of it; or, if questioned on the subject, denies it altogether. The cough is short, tickling, and hacking, rather than very severe. With this cough there is generally spit up only a little mucus;—either at the same time, or soon after its commencement.

*Stitch in the Side.*—It is very common to hear the patient complain of “a stitch in the side,” generally low down; and one would think it was a slight pleuritic affection; only that sometimes the stitch is undeniably felt beyond the chest in the parietes of the abdomen. I have known a very violent stitch, before any other symptoms of phthisis, low down in the abdominal muscles, out of the way of the chest; so that these pains, though they are occasionally pleuritic, are, I have no doubt, very frequently muscular.

*Cough increases at Night.*—The cough is generally worse when the patient gets into bed; owing, I presume, to the coldness of the sheets; or when he rises in the morning;—from the coldness of the atmosphere of the room, compared with the warmth of the bed. There is felt a little shortness of breath on motion;—on any exertion, the patient finds that his breath is not so good as before; and he complains of languor.

*State of the Surface.*—The flesh becomes soft; so that on taking hold of the arm of a patient, even at this time, we find it is flabby. The hair loses its strength; so that it cannot be kept in order as before. This occurs particularly in females. There appears to be a softness of the hair; which will not allow it to remain in the way in which it has been placed.

*Feverishness.*—There is also observed, about this time, a little feverishness. The pulse is found to be quicker than natural; and this comes on particularly after the least exertion. An exertion which before would quicken the pulse only perhaps ten beats, will now quicken it twenty or thirty, in a minute. On falling asleep, it is very common for patients to find that they sweat in some one part of the body;—in the calves of the legs, for instance, or upon the chest. The power of resisting external temperature is diminished; so that the patient complains of chilliness.

*Character of the Sputa.*—The expectoration, although only mucous originally, now becomes sanguineous. Perhaps the patient never had hæmoptysis, but the complaint has begun with the general symptoms I have mentioned; but he tells us, on one of our visits, that what he has spit up was brown, or tinged with blood. That is another form, in which a discharge of blood takes place. Very frequently there is the hæmorrhage which I before mentioned; but more frequently, perhaps, there is no such thing as any decided hæmoptysis; but the mucus, after a time, becomes a little streaked with blood.

<sup>a</sup> See Pages 785 to 788.

<sup>b</sup> From *αἷμα*, blood; and *πύω*, to spit.

<sup>c</sup> See Page 762.

*Second Stage.*—There is now more cough, more dyspnœa, and more debility than before; and the patient begins to find, that he lies more easily on one side than on the other. The patient finds his strength decrease; or, if he do not himself allow it, yet it is evident to others. He cannot make the same exertion as before; and it is also pretty evident that he loses flesh. Occasionally there is a sharp pain in the side, of a pleuritic character;—so as to make it necessary to take away a little blood. There is clearly inflammation of the pleura. If the patient be a female, menstruation is almost sure to decline. The catamenial discharge loses its natural redness; becomes paler than it should be; and, as well as being thus impaired in quality, becomes more scanty in quantity; and, more frequently than not, ceases altogether.

*Incurvation of the Nails.*—Generally, as these symptoms proceed, the ends of the fingers become enlarged. The last joints of the fingers look broader than they did before; the whole appear tumid, and the nail is particularly prominent. The eyes, too, become very clear. There is a whiteness and transparency of them, which did not exist before;—the sclerotica looks of a more intense white than natural. The nails sometimes become very considerably incurvated. The whole nail is more convex than before; and, I believe, rather softer,—like the hair; and that part of the nail which is unattached to the cutis, is in many instances very much bent. The hair, which at first is only soft, and with difficulty kept in order, now generally falls off.

*Change in the Character of the Sputa.*—The expectoration, from being mere frothy mucus, now becomes a little green, or a little yellow, and more abundant; and, instead of being long and stringy,—like the expectoration of health,—it becomes short between the fingers. Now and then the expectoration becomes fetid, the strength very much declines, the sweating at night becomes very profuse, and the expectoration decidedly sinks in water; whereas, before, either the whole of it or the greater part swam. Shreds are seen in it, whiter than the rest; like curdy lumps, or fragments; and, in some few instances, we may observe earthy matter in it. The latter is, by no means, so frequent an occurrence as the former; but it occurs now and then.

*State of the Tongue.*—The tongue will sometimes remain in a healthy condition; but in most instances it becomes loaded with mucus, and is foul and yellow, on the one hand; or becomes red at the edges and tip, on the other. Sometimes it is of an intense redness all over; so that it looks like a piece of beef.

*Third Stage: Hectic.*—There is now an increase in the pulse at two periods, at least, in the day;—that is, in the middle of the day and in the evening; but decidedly in the evening. There is a great exacerbation of it, together with heat of the body, after every meal. The pink sediment of hectic<sup>a</sup> appears in the urine; and the pulse is constantly much quicker than it should be; perhaps seldom below ninety, and frequently above a hundred. The mind and the appetite remain unimpaired. Persons labouring under this disease, will frequently eat heartily to the very last;—have a perfectly good digestion; and their mind is as alive and active as it ever was;—perhaps more so. Patients generally have hope. They will not believe they are in a dangerous state;—they do not think that their case is consumption. On the other hand, when people are not active, and think they are labouring under phthisis, in nine cases out of ten there is no danger whatever. A remarkable feature in the disease is this hope. Even medical men, who have fallen victims to phthisis, have insisted, up to the day of their death, that they had not ulceration of the lungs; and that they should get well. This has been observed in intelligent men, as well as in those who were most stupid. It is not a matter of judgment, but of feeling; and hope is quite characteristic of this disease, though it is by no means an *invariable* circumstance. Now and then persons despond;—being quite aware that the disease is well established and confirmed; but, in a much greater number of instances, there is the most lively hope.

<sup>a</sup> See Page 268.

*Colliquative Purging and Sweating.*—In the greater number of cases, the intestines suffer very much. Perhaps, at the beginning, the intestines are a little dormant; but as the disease proceeds, and especially at the last, the intestines fall into a state of diarrhœa; and the purging very frequently alternates with the sweating. The purging is so severe, that it may be said to melt down the patient, and therefore is called “*colliquative purging*,” and the sweating is so profuse, that it is called “*colliquative sweating*.” The expectoration becomes more yellow and green than before; and it also becomes more abundant. The cough becomes more severe; the legs become œdematous; and the body wastes exceedingly. The hectic flush is seen, decidedly, upon the cheeks and palms of the hands;<sup>a</sup> and the exhaustion is such, in some cases, that the patient frequently faints. He feels exceedingly languid. The patient is, at last, confined to his bed in all cases; but, in some instances, there is great tendency to syncope, and dyspnœa from debility; so that stimulants are required. Just before death, the brain is sometimes affected; so that there is frequently delirium, three or four days before death.

*Varieties in the Symptoms.*—The progress of all these symptoms, is exceedingly various. Sometimes only a few weeks, but in other cases, many years elapse before the patient sinks under the affection. I am convinced that I have seen cases, where there were no symptoms of phthisis; and yet the patient has died from ulceration of the lungs, in the course of three months. I recollect one instance of this particularly. On account of some anomalous symptoms in the abdomen, the patient was frequently examined by me. He was two or three miles from London; and, on carefully examining his chest, I found that he was free from cough, and from all the symptoms of phthisis generally; as well as from those symptoms which can only be learned from auscultation. He then began to expectorate, showed signs of phthisis, and died. On the autopsy we found ulceration. All this occurred in the course of two months. The public at large are aware of this state; and they give to such cases as these, the epithet “*galloping consumption*.” On the other hand, the disease will last, there can be no doubt, for very many years; that is to say, persons will have cough, and expectorate; yet it will not increase, but decline from time to time; and so they will go on, till at last they expectorate a great deal, and die in the usual way. Dr. Gregory, of Edinburgh,<sup>b</sup> used to say that he knew a case, where a person was in a state of consumption for fifty years; but it is impossible to say that the patient laboured under *phthisis* all the time; it might have been only *bronchitis*. But it is a fact, that there is very great variety as to the duration of the disease. It is generally quickest in those who have the finest skins, and are nearest the period of puberty; or who are not very much beyond that period. The disease is frequently suspended, on the other hand, by pregnancy, and by suckling; and now and then it has been suspended by other diseases, as by ague or insanity. These, however, are only occasional circumstances.

*Auscultatory Signs.*—We are now prepared to understand those symptoms, occurring during the progress of this disease, which are acquirable by the ear. At the first period of phthisis, there is nothing (in my opinion) to be learned by the ear. It is from the general appearance of the patient, and from the general symptoms of which he complains, that we suspect the presence of phthisis. At the onset, it is at most only a matter of *suspicion*. We cannot be *certain* of it. It is easy to perceive that this must be the case, when we consider that, in the first instance, the tubercles which constitute this disease, are exceedingly small and exceedingly few;—leaving a large portion of pulmonary structure perfectly healthy. It is only when the tubercles increase to a certain size, and approximate,—so as to form a mass, or when a considerable portion of the pulmonary structure is beset with tubercular deposit, that we can expect to discover any audible change.

*Percussion in the First Stage.*—The parts in which the symptoms acquirable by the ear may be noticed, in the first instance, are below the clavicles. This may

<sup>a</sup> See Page 96.

<sup>b</sup> See Note to Page 239.

be observed before the tubercles have softened; but when they become sufficiently large and numerous to occupy some space, on striking over the part where such deposit exists, we do not find the hollow sound of health, but a greater degree of dulness than there was before. In proportion to the size of the tubercular deposit, is the dulness of the sound; and we may save ourselves a great deal of trouble, by beginning our examination at the clavicle, and immediately under it. Still, if we have any suspicion, and yet the parts below the clavicle sound well, we should examine other parts; because now and then the deposition, instead of taking place there, occurs in other situations. In the great majority of cases, however,—I may say in nine cases out of ten,—the change takes place just below the superior portion of the lungs; and therefore we should commence our examinations there.

*Stethoscopic Signs in the First Stage.*—Besides this dull sound on percussion, if we listen with the stethoscope, and make the patient speak, we find the voice resound there in an unnatural manner. The solid substance of the tubercles, is so much better a medium of conveying sound, than the loose structure of the healthy lung, that the sound is louder where these tubercles exist than elsewhere. The voice will not come through the tube, as if the patient's mouth were at the other end of it, speaking to us; but we hear the sound echo; and it is louder than natural. There is no pectoriloquy; but we have what is called "bronchophony;"—the same sound that is heard on putting the stethoscope over the large bronchia.<sup>a</sup> But it is to be remembered, that the voice naturally sounds louder under the clavicle than elsewhere, on account of the large tubes being there; and therefore we should not depend on this symptom alone. It should be united with the dead sound on percussion, in order to satisfy us that there is bronchophony dependent upon tubercular deposition. It is well to compare the sound on each side; for the deposition generally takes place more on one side than on the other; and frequently it occurs *only* on one side; and our suspicion will be increased, as to the really unnatural loudness of the voice, if we hear it louder on the one side than on the other. The difference of the two is frequently very manifest.

*Pectoriloquy.*—But when the tubercular mass softens, and a portion is discharged,—so that the cavity is emptied, or nearly so,—a new symptom occurs. The bronchial tubes, we know, enter this cavity; and as the air enters it, the same state of parts exists there as in the trachea;—that is to say, there is a large space, into which, on inspiration, the air enters; and consequently, when the patient speaks, the same sound is heard that occurs on putting the stethoscope over the trachea. If we place the stethoscope over the trachea, we have the voice traversing the tube, as though the mouth were at the other end; and just the same occurrence takes place, when we put the stethoscope over a cavity in the lungs;—we have the phenomenon called "pectoriloquy."<sup>a</sup> If we make the patient cough, a mucous rattle is heard;—the same sound as if air were forced through soap-suds. It is a gurgling sound, arising from air agitating a viscid fluid.<sup>b</sup> But as the contents grow less and less viscid,—as the curdy matter of the scrofula is more and more spit up, and mere mucus forms more and more the contents of the cavity, the gurgling is heard louder, and is found to be freer. Then, if we make the patient breathe quickly, and at the same time rather deeply, we hear the same sound that we do if we make him breathe quickly, and put the stethoscope over the trachea. In the latter case, we have the sound of the air evidently going through a large space; and the same circumstance occurs in the former instance;—merely arising from the part being of the same description as the trachea. We have the same phenomena with respect to simple respiration, the same phenomena with respect to the voice when the patient speaks, and the same phenomena when we make him cough, that we have when we place the stethoscope over the trachea;—that is to say, we have pectoriloquy. We may, however, have the same symptom of pectoriloquy in the most perfect health, if we listen over a certain part of the chest;—especially in thin

<sup>a</sup> See Page 712.

<sup>b</sup> See Page 709.

persons. On placing the stethoscope between the clavicles of a person who is thin, we have pectoriloquy; because the large bronchia going to the lungs, emit the sound of a tube, even if the individual be healthy. We must not, therefore, pronounce a person in a state of phthisis, simply because there is pectoriloquy between the clavicles; but when it is heard decidedly in other parts of the chest, then there can be no doubt as to the nature of the case.

*Percussion in the Second Stage.*—When the disease has reached this stage, we no longer have the dull sound on percussion, that we had in the first instance.\* The tubercular solid mass, which gave the dull sound on percussion, no longer exists; and consequently there can no longer be the phenomenon which it produced. That phenomenon was a dull sound, from the part being solid. The part is now hollow; and, on striking over it, we find the sound as hollow as in health, and perhaps *more* so.

*Pectoriloquy does not indicate the nature of the Cavity.*—It is to be remembered, that though we have pectoriloquy, and thus have a large space which ought not to be there, yet the phenomenon does not show the nature of the cavity; and it is only from the general symptoms, that we are satisfied it is the cavity of phthisis. In gangrene of the lung, a part of the latter is sometimes separated and discharged; leaving a cavity which may give rise to pectoriloquy. But then we know that it arises from gangrene by other circumstances;—such as the great debility of the patient, and the fœtor of the expectoration. In chronic bronchitis, the bronchial tubes may be very much enlarged at one spot;—as large as the bronchia themselves, or approaching to their size; and in that case we shall have pectoriloquy; but then there will not be present the general symptoms of phthisis, and thus we may suspect the nature of the case. No reliance, then, is to be placed on the ear alone: the symptoms which are *audible*, are only to be taken in conjunction with those which are *general*. Persons find fault with auscultation unjustly, who suppose it is employed to the exclusion of attending to other symptoms. No person who uses his ear, is justified in making so absurd an application of it. He ought to be careful in adopting all the means of making observations within his power. A person may be labouring under ulceration of the lungs; and yet he may not afford the sign of pectoriloquy. If the cavity be near the surface of the chest, and the walls of the cavity be very thin, and if the bronchial tubes that open into the cavity, have mouths so small as to bear no proportion to the cavity itself, we may have a large cavity, and yet no pectoriloquy at all. Here, again, is an instance of the fallacy of the observations made by the ear alone, to the exclusion of the other symptoms. Like every body else who has attended to these matters, I have over and over again opened patients, and found a large cavity after death; where, before the fatal termination of the case, there had been no pectoriloquy at the affected spot. The walls of the cavity must be a certain thickness, for the phenomenon of pectoriloquy to be produced; and the bronchial tubes opening into the cavity, must bear a certain proportion to it; for when the cavity is near the surface of the lung, and the substance of the lung has been entirely destroyed, so that there is merely pleura forming the parietes of the cavity, we cease to have pectoriloquy. If, however, we had seen the patient before the cavity became so large, as to be out of proportion to the bronchial tubes opening into it, and the walls became so much diminished, then we should have had pectoriloquy. But we may not have been called in before the patient arrived at this state; and therefore may not have had an opportunity of observing the successive changes.

*Metallic Tinkling.*—When an excavation is very large indeed, we sometimes have another phenomenon;—which is called “metallic tinkling.” By this is meant a sort of silvery, ringing, metallic sound, when the patient coughs, speaks, or breathes; but particularly when he coughs;—a clear metallic ringing, which can hardly deceive us. But the sound is not peculiar to this affection; for when the surface of the lung is ulcerated, and air escapes into the pleura, that being a very large

\* See Page 792.

cavity, it just gives us the same phenomenon. When air enters into the pleura, we have metallic tinkling, from the presence of the air and fluid together; but if it so happen that there is a large cavity in the lung, that will come to the same thing; and the air and fluid entering into it, will give rise to the same sound. The cavity, however, is seldom so very large as to produce it.

*Value of Auscultation in Phthisis.*—We seldom examine a patient at that point when much information is to be derived from the ear. In the first stage of the disease, there is nothing to be learned from it; and as the disease proceeds, the case is generally perfectly clear, without the use of the ear; but if a set of symptoms do present themselves to the ear, they are as worthy of being observed as those that present themselves to the eye; and the mere trouble of examining them, can be no excuse for not observing them. Unfortunately, in the great number of instances, the case is too severe to render such examination necessary; but cases do occur where the disease is not so severe; and some will say that the affection is *bronchitis*, while others assert that it is *phthisis*. Persons are said every day, by those who do not use the ear, to be in a state of phthisis, when they are not; and *vice versa*. Now if the ear be used after a certain time, and we ascertain the existence of a cavity; this, in conjunction with the other symptoms, will render the case clear. The examination must not be too late; or the phenomenon of pectoriloquy may have ceased. It is of great importance to be able to say that there is pectoriloquy; for a practitioner may have said that it is not phthisis at all, and he will stick to it; but if, on listening, we hear pectoriloquy, we may be sure that he is wrong; and may be able to convince him of it. It is a fact that some practitioners who have taken a predilection for other organs,—particularly the liver, or the viscera of the abdomen,—may declare that there is no such thing as phthisis present; while it is evident enough that the patient's lungs are rotten. Now if, in a case like that, we can induce a person to listen to us, and can show him the difference between the sounds in health, and those in this disease, we may open his eyes, and bring forward such an argument as cannot be resisted. It would be unphilosophical not to know these things; and not to attend to them if they do exist.

*Complications.*—Besides those morbid appearances and those symptoms which I have now mentioned, as occurring in phthisis, a variety of others occur in different patients. Some have very great disturbance of the digestive organs; some have tenderness of the epigastrium, tenderness of the abdomen where the small intestines lie, and tenderness likewise of the liver. Some have very little appetite; but a large number have an *excellent* appetite; and eat and digest well, to the last moment of their existence. It is very common for a fistula to form by the side of the rectum; and it is very common to find, after death, a considerable inflammation of the mucous membrane of the intestines. It is by no means uncommon to find the intestines ulcerated; to find a scrofulous deposit in the mesenteric glands; and to find the liver more or less diseased. The French have attended very minutely, to the proportionate occurrence of these different morbid affections of other parts. We find in the work of M. Louis (a physician now living in Paris), the most accurate information on this point.<sup>a</sup> It is very common to find the trachea ulcerated;—to

<sup>a</sup> We subjoin the following summary, from Louis's admirable work on Phthisis (translated by Dr. Cowan), of the various complications which occur in phthisis, and their relative frequency:—

"Tubercles and pulmonary excavations were, in one-tenth of the cases, coincident with recent inflammation of a portion of one or both lungs, of the pleuræ; or with the effusion of a notable quantity of limpid fluid in the thoracic cavity.

The trachea presented ulcerations, often of considerable size, in rather less than one-third of our [M. Louis's] observations. Its mucous membrane was merely reddened, sometimes slightly softened or thickened, in one-fifth. The larynx was ulcerated in rather more than one-fifth, and the epiglottis in a nearly similar proportion.

The pericardium contained a marked quantity of clear fluid in one-tenth of the cases, and presented traces of chronic or recent inflammation in many others. The heart was pretty frequently softened; the aorta was red in the majority of young patients, and its structure more or less modified after the age of forty.

In one-twelfth of the patients the stomach was dilated, and situated lower down than natural.

have a scrofulous deposit in various parts of the trachea; particularly about the larynx. In some instances there is soreness, violent cough, and every other mark of chronic disease of the larynx; whereas, in other cases, there is no hoarseness, or other sign of affection of the larynx or trachea; except a little inflammatory irrita-

Its mucous membrane was red, sometimes mammillated, a little softened, and thickened anteriorly, in nearly the same proportion. In one-fifth it was more or less extensively thinned. We found it in the same proportion very red, softened, and sometimes thickened in the great cul-de-sac; it was ulcerated, of a more or less grayish tint, and mammillated in many others, &c.; so that it was only healthy in one-fifth of our examples.

In the small intestine there were ulcerations, varying in number and extent, in five-sixths of the patients. They were nearly as frequent in the large intestine; of which the mucous membrane, often red, and in one-half of the cases thickened, was either wholly or partially of the consistence of mucus; so that we have only three times seen it perfectly healthy.

The tuberculization of lymphatic glands was less frequent in the neck, loins, mesocolon, and axilla, than in the mesentery; where it existed in various degrees in one-fourth of the cases.

The liver had become adipose in one-third of the examples. The parietes of the gall-bladder were occasionally thickened and ulcerated; and when this was the case, as also in some other circumstances, it contained calculi.

The spleen was softened, and under or above its natural volume, in a great number of instances. It was tuberculated in one-sixth. This last alteration was nearly equally frequent in the kidneys, where we sometimes discovered cysts.

In many individuals the prostate was tuberculated; in one of these there was an example of tubercular exhalation in the interior of the vesiculæ and seminal ducts. We have once seen the internal surface of the uterus converted into tuberculous matter.

From one to six pints of clear serous effusion in the abdomen existed in one-fourth, and a small quantity of pus, or some false membrane in the pelvis, in four of these instances. We have seen several cases of tubercular peritonitis. In one the great omentum and the mesocolon presented a mixture of gray, bluish, semi-transparent and tuberculous substance.

The cerebral arachnoid was often partially thickened; presenting more or less numerous granulations in its upper portion, especially near the falx. In two cases it was lined by a yellowish and soft false membrane. The tissue uniting it to the "pia mater" was infiltrated, and the ventricles distended by a very appreciable quantity of serum, in three-fourths of our examples. The same fluid was found in the inferior occipital fossæ; but less frequently, and not so abundant. In one-seventh the brain was injected; in one-twentieth, its consistence was generally diminished, and in one instance to a remarkable extent. Its partial and pulpy softening was observed in the same proportion. All the serous membranes were thus very frequently the source of effusion; and it is in the lateral ventricles of the brain that this was most generally observed. The same membranes were also liable to acute inflammation, coming on towards the close of life; and this was most frequently the case for the pleuræ.

In some instances, many of the morbid states just glanced at,—as the softening and thinning of the gastric mucous membrane, and the ulcerations of the intestines,—were sufficient of themselves to have caused death, independently of the lungs. The period to which the commencement of these different alterations could be referred, was very variable. Pneumonia, pleuritis, softening and redness of the great cul-de-sac of the stomach, pulpy softening of the colon, peritonitis, arachnitis, partial and pulpy softening of the brain, could all originate a few days previous to death. The greater part were the result of inflammation;—plainly proving that *weakness*, so far from being an obstacle, is (on the contrary) favourable to inflammatory action. The other alterations, dated much further back, sometimes to the very commencement of phthisis; as, for instance, softening with diminished thickness of the mucous membrane of the stomach; and, in some cases, the large intestinal ulcerations.

These various morbid changes admitted also another division; some were peculiar to phthisis, others were not so; but were present in different degrees, after a variety of other chronic affections.

Among the first class may be enumerated ulcerations of the larynx, and more especially of the trachea and epiglottis; ulcerations of the one or both intestines (principally of the small); and the adipose state of the liver: so that by seeing an ulceration in either of the organs mentioned, &c., we should be able to assert, independently of all farther investigation, that the patient had died of phthisis. These ulcerations, wherever they were situated, in their mode of production presented many points of resemblance. When the mucous membrane was destroyed, the sub-mucous layer gradually thickened, and became uneven; after a time, it ulcerated, and then the muscular coat in its turn began to thicken: this was, like the former, subsequently destroyed (though its total destruction was extremely rare); so that in proportion as one of the coats of the intestine became ulcerated, the succeeding one thickened; and, by thus opposing greater resistance to its destruction, protracted the fatal termination.

The last morbid alteration peculiar to phthisis, were *tubercles*, wherever they might be

tion, indicated by an excessive secretion of mucus. Now and then, serofulous tubercles are found in the brain, or at least under the "pia mater;" but, for the most part, the head remains perfectly free.

### SECTION III.—DIAGNOSIS AND PROGNOSIS.

*Diagnosis.*—With regard to the *diagnosis* of the disease, it must be made out by general observations respecting the patient;—general observation as to predisposition, and as to constitution. Then, again, as to the *progress* of the disease, if a person has had, for a great length of time, cough, which has generally increased; if there has been a falling away in flesh; and the individual has not passed the middle period of life, but is between eighteen and thirty;—if these symptoms occur, and there has been phthisis in the family, we have still greater reason to suspect the formation of tubercles. If, in females, there be a suppression of the menses; if, in males or females, the ends of the fingers become enlarged, and there are frequent attacks of hæmoptysis, together with a continual cough,—the case will be rendered still more suspicious. By means of the stethoscope we may ascertain, after a time, whether there is a cavity or not; but the diagnosis of this disease is too easy, after the affection has once formed.

*Prognosis.*—The prognosis, in these cases, must always be unfavourable. If one part of a lung be beset by tubercular deposition, it is possible that the substance may soften, be expectorated, the part heal, and the patient do very well. It is possible that, notwithstanding the presence of pectoriloquy, and other signs of confirmed phthisis, yet the patient *may* recover. Such things, however, are exceedingly rare. I doubt whether it is a common thing for these excavations to heal; but it is a far more uncommon thing for the patient to get well; because, in general, the disease is constitutional; and if one excavation should heal, a crop of tubercles occurs in some other part, and goes through successive changes; and under these the patient will sink. On opening a patient who has died of phthisis, we almost almost find tubercles in various stages; and if we could heal one lung entirely (as it has been proposed to do, by making an opening into the chest, and causing the lung to collapse) I doubt whether we should do much good; because the other lung is generally beset with tubercles, which will regularly go through their stages in the same way.

*Cicatrization a rare Occurrence.*—Laennec says, that he has frequently seen a cicatrix in the lungs;—that a cavity had existed and healed; that the sides had come together; and the part become solidified and hardened;—just as is the case with a cicatrix on the surface of the body. The appearance spoken of by Laennec, as indicative of a healed cavity, is a depression, or a puckering, on the surface of the lung; just as in a cicatrix on the surface of the body, when there has been an abscess below. If there be merely superficial ulceration, we know that a scar is left; but in proportion to the depth of the ulceration on the surface of the body, and in the parts immediately below the surface, so is the depth of the cicatrix and of the puckering. This appearance is sometimes seen on the surface of the

found. We [M. Louis] have never observed them in *a single* instance in any organ, without their existing in the lungs; so that their presence in these last viscera, seems a necessary condition for their development in other parts. Another fact which strengthens the idea of this dependence is, that, with one single exception, we have always seen the tuberculous matter more advanced in the lungs than elsewhere; and when tubercles existed at the same time in different parts of the body, these were always at the *same degree of development*; and it would be difficult to conceive this uniformity, in parts so distant from each other, and so various in structure, unless we admit the influence of one and the same cause, acting simultaneously on a great number of organs; thus making tuberculous deposition quite independent of those occasional causes, which we are apt to suppose active in certain cases.

As our object, however, is not to support one opinion more than another, we [M. Louis] will remark, that we have found one exception to the law we have established. It was in a case of typhus. No tubercles existed in the lungs; and yet there was a small quantity of tuberculous matter in the mesenteric glands." (Pages 115 to 118.)

lung; and Laennec says that, on cutting down on such a part, we find below it induration, to a greater or less depth. My reason for doubting this is, that we see exactly the same appearances upon the liver. Almost every month, if we open many bodies, we find a puckering on the surface of the liver;—a depression, with a puckering all around it; and, on cutting into it, the substance of the liver appears unnatural as to colour. But there is no ulceration; in fact, there *could* have been no ulceration,—no suppuration; for there are no signs of there having been any matter. The peritonæal surface of the liver will fall into a state of chronic induration; here and there it will become indurated and hard, and it is commonly puckered; and there we have the appearance of so many scars. The same thing will take place in the lungs. They may seem puckered, and the pleura may be very hard there; but that is not a sufficient reason to my mind, for believing that there is a cicatrix. It is common, when there has been a slow thickening of the pleura,—to say nothing of inflammation,—to find the lobes glued together, and the pleura between the lobes thick, and almost cartilaginous. Sometimes there is a puckering on the surface; and, on cutting down, we find a cartilaginous hardness to some depth;—from cohesion of the different lobes. Independently of that, the pleura will fall into the same sort of disease as the peritonæum over the liver; and will produce just the same appearances. On reading Andral, I find that he has come to the same conclusion as myself; and I have no doubt that others have done so likewise. It is said that, now and then, a cicatrix may be produced; but I am sure it is a rare occurrence.

*Evacuation of the Tubercular Deposit.*—But sometimes people, without any cicatrix, get rid of this tubercular deposit. When it has occurred only at one spot, an open cavity remains; and the patients live for a long time. It is so common, however, for tubercle after tubercle to take place in the lungs, and go through successive changes, that people generally do not live. It certainly does happen, sometimes, that the lining membrane of these cavities becomes hard, secretes a quantity of mucus, and so remains during the rest of life. No further mischief is done; pectoriloquy is always heard; and the patient is only troubled with cough and expectoration. But this is comparatively rare.

*Terminating in Pneumato-Thorax.*—Now and then,—but this likewise is an uncommon occurrence,—death will take place from ulceration extending outwards through the pleura. In cases of this description, the patient is generally seized with a sudden difficulty of breathing. On striking the chest, there is a very clear sound; and (as may be supposed from the air escaping from the lungs to the pleura) the lungs become more and more collapsed. If it occur on the left side of the chest, the force of the air will be such, as to drive the heart to the right side. This is called "*pneumo-thorax*;" but, as I shall afterwards point out, it should be termed "*pneumato-thorax*." I shall describe this more particularly, when I come to diseases of the pleura; but it is to be remembered that, now and then, ulceration is not confined to the lung itself; but that the pleura becomes ulcerated, or is rendered so thin, that it gives way; and then we have air and fluid in the pleura. In general, nature prevents this,—however near to the surface the cavity may be,—by causing adhesions. I mentioned<sup>a</sup> that when a tubercle is near the surface of the lung, the pulmonary and costal pleuræ (one or both) throw out lymph, and become glued together; so that ulceration may go on within, and yet neither air nor fluid can escape into the pleura. But now and then nature fails. A tubercle exists near the surface; the ulceration goes on; no adhesions take place; a perforation is produced by the ulcer; and the phenomenon of air and fluid in the pleura occurs.

#### SECTION IV.—CAUSES OF PHTHISIS.

*Hereditary Predisposition.*—There can be no question, that the disposition to

<sup>a</sup> See Page 788.

this disease is frequently constitutional, and frequently hereditary. Those who are most subject to it, are usually fair persons; with light hair, a sanguineous temperament, soft skin and hair, and long pointed fingers. Their flesh is flabby,—not firm; and the pupils of their eyes are large. They are frequently thin and tall; but whether they are tall or not, persons of this description are slender, with a long neck. Frequently, too, such persons have been subject to hæmorrhage from the nose when young. There is another description of persons subject to phthisis;—comprehending those who are not tall, but short; and who have not light hair and a fair skin, but are rather swarthy, and have dark hair and dark eyes. These also have large pupils, and their skin is rather soft; and, instead of having *long*, they have *short* fingers and nails. Like the others, they are of a lax fibre;—their muscles being flabby; and persons of this latter description generally have a tumid upper lip. There are, therefore, two descriptions of persons most liable to phthisis. Both, in general, have a soft skin, soft hair, a flabby fibre, and a pale look; but those of one set, if they be not tall, are slender; and generally have light hair and a florid complexion; and are disposed to hæmorrhage; whereas the others are short, with dark hair, a tumid upper lip, and short truncated fingers. This form of body is (of course) constitutional; and it likewise may be hereditary.

*Age.*—A certain age is more liable to the disease than any other. In this country, scrofula is more likely to occur, in the lungs, between the age of eighteen and thirty, than at any other period. When it occurs later than this, it is perhaps more frequently the result of unfavourable external circumstances, acting upon constitutions moderately disposed to it, than of the mere intensity of the predisposition.

*Food, Temperature, and Clothing.*—There can be no question that it is greatly predisposed to by bad food, bad lodging, and bad clothing. Many would escape the disease, were it not for their being exposed to wet and cold, being badly protected in the way of lodging or of clothing, and not fortified with the means of resisting wet and cold, by good food. The latter keeps up a good fire within; and compensates, in a great measure, for the unfavourable state of the atmosphere. Hence the disease is much more frequent in countries which are wet and cold, than in others; and it is more frequent in countries which have cold and wet alternating with warmth, than in those which are simply cold. For example: I believe it is not so common in Russia, as in many other warmer parts.

*Alternations of Temperature.*—Alternations of temperature, especially cold and moisture (united) alternating with a warm temperature, seem to have the greatest effect in exciting the disease; and to be the great predisposing cause,—next to hereditary, constitutional disposition; or the want of food, clothing, and lodging. It is far less frequent in *tropical*, than in *temperate* climates. Indeed, it is said that real strumous phthisis is unknown in the tropics, or is confined to European settlers; who bring the disposition to it from unfavourable climates. It is a disease seen, more or less, in all parts of the world, or nearly so; either occurring among the inhabitants, or among those who come from countries where it is very common. Some ascribe the comparative rarity of the disease (I only say “*comparative rarity*”) in Russia, to the circumstance of the people having good clothing;—being clad with furs and other warm materials, and eating plenty of animal food. All the inhabitants of cold climates, eat a large quantity of animal food; while those who inhabit warmer regions, care little about it, and live principally on vegetables. The diets of Italy and Russia are completely different. To show the effect of clothing upon the disease, it is said that it was unknown in Scotland, before the people changed their dress from woollen to cotton. I suppose that is an exaggeration. It is alleged, that formerly, in Scotland, the people were all dressed in woollen,—as the Romans were; but that since they have changed it for cotton, the disease has become very prevalent. The disease is said to be the least prevalent among butchers, fishermen, and fishwomen (in Scotland, called “*fishwives*”). The cause is said to be, that these people eat plentifully of animal food.

When the predisposition is very strong, the most favourable external circum-

stances can scarcely keep away the disease. We see a family, brought up with every care in guarding against cold,—having good food, good clothing, and good lodging, and attention paid to the slightest indisposition; and yet, one after another, —especially if they be females,—they become the victims of this disease. On the other hand, where the disposition is not so strong, by taking great care to avoid vicissitudes of temperature, to dress very warmly, and to be well nourished, people escape it. If persons who have this disease in their respective families, who themselves are disposed to it, and perhaps afterwards (one or both) die of it, intermarry, the affection is almost sure to be transmitted to the offspring. Every one must have seen instances of the death of children, whose mother died some years before of the same disease. Where two first cousins marry together, the predisposition derived from this unfortunate mixture becomes so powerful, that a very phthisical offspring is generally the result. Whoever belongs to a phthisical family, should endeavour to “cross the breed,” by marrying some one that is not phthisical; because, although it is delightful to marry a lady delicately beautiful to all appearance,—having white teeth, a fine skin, soft hair, and so on,—yet misery is almost sure to be the consequence. The disease is almost certain to begin; and the offspring perish one after another.

*Exciting Causes: Cold and Wet.*—The immediate exciting cause of the disease, when one is apparent, is generally that of any common inflammation,—any common cause of catarrh. Exposure to cold, more particularly cold and wet, especially when applied partially, and (again) especially when the body is overheated, is the most common exciting cause. Persons with a strong predisposition, catch cold from the slightest causes;—from something that would be insufficient to give another individual cold; and what would be mere *catarrh* in one person, becomes in the other the commencement of *phthisis*. Sometimes tubercles have already existed in the lungs; and these merely produce inflammation in the organ. In other cases, inflammation is induced in the air-tubes; and, the disposition being strong, the debilitating effects of the inflammation lead to the production of the tubercles.

*Mental or Physical Exhaustion.*—Whatever exhausts the body, many produce the disease. When persons are predisposed to it, they will have it come on without catching cold at all; but simply from over-exertion of the body, or over-exertion of the mind. But where there is mental exertion, there is almost always anxiety. It is seldom that a person is occupied mentally without anxiety; and therefore anxiety may, in a great degree, be the cause of the disease. There can be no doubt that the depressing passions will produce the disease. I have seen a case where, in a predisposed family, an individual has become the victim of phthisis, decidedly from the very time that some great source of grief occurred to him.

*Powdery Substances.*—Powdery substances in the atmosphere, have excited this disease;—not simply in cases where there was a strong predisposition to it;—but where the powdery dry substance is of a hard nature, (such as portions of metal, or of stone,) the disease is produced with scarcely any discoverable predisposition. There are certain occupations, in which fine particles of stone are diffused through the atmosphere; and others in which fine particles of *steel* are so diffused; and the persons exposed to these, very frequently die of phthisis; so that, in some parts of the country, where these trades prevail, few men, who work at them, live beyond forty; and many die much before that time.

*Contagion?*—It has been supposed that the disease will arise from contagion; but it is in foreign countries that this idea prevails. It is believed in Languedoc, Spain, and Portugal; and the clothes of patients who have died of this complaint, are there burned by the civil authorities. Morgagni was so frightened at the contagiousness of this disease, that he never opened the body of a person who died of it; but that was evidently the result of a little nervousness, rather than of his better judgment. It is mentioned as being contagious by Morton, a writer on this disease in our own country; but it was not so considered either by Hippocrates or Celsus. I do not believe that it is in the slightest degree contagious. Like others

practising medicine, I have seen hundreds and hundreds of cases of the disease, but I never saw an instance, in which there was a shadow of probability for the doctrine of contagion. I have seen husbands nurse their wives, and wives their husbands; and I am quite sure that where the survivor has become phthisical, the proportion has not been greater than we might expect, where a disease is so prevalent as phthisis. It is not uncommon for persons in the same family to fall into it, where there is great anxiety. I hardly recollect a case where the husband has died of phthisis, and the wife has fallen a victim to it immediately afterwards, where there has not been a predisposition to it. I have seen so many hundreds of examples of the reverse, that I do not think the proportion is greater than it would be, if it were a matter of absolute certainty that the disease is not contagious at all.

*The Presence of other Diseases.*—The presence of other diseases will excite this. It is very common for phthisis to come on after inflammation of the lungs, and after severe bronchitis, peripneumonia, or pleuritis; but it is certainly very often the case, that the inflammatory disease which has preceded it, has been the result of a general predisposition to disease in the region of the chest.

*Sedentary Occupations.*—Sedentary occupations, of all descriptions, must be unfavourable in this disease; because, in sedentary occupations, there is a want of fresh air, as well as of due exercise. In such occupations, too, there are generally many persons collected together; and unhealthiness, of all descriptions, must be engendered.

*Great Respiratory Exertion.*—With some, the exciting cause has been great respiratory exertion;—such as excessive public speaking, excessive reading aloud, excessive blowing of wind-instruments; and some have had symptoms of phthisis, which have declined after giving up the flute, or some other wind-instrument.

*Mercury.*—The disease has frequently been excited by mercury. It is very common for us to see persons who have been in the foul wards of an hospital, and undergone a considerable administration of mercury, fall into a state of phthisis.

*Excessive Venery.*—Excess in venery is likewise, by no means, an unfrequent exciting cause. I have seen many young men die of phthisis, a twelvemonth after their marriage; although they have shown no signs of it before.

We sometimes have an abscess of the lungs;—sometimes an abscess of the *liver*, making its way, and producing an adhesion to the diaphragm, and of the diaphragm to the lungs, and so on; but all this is not *phthisis*. Where, however, there is a great predisposition to the disease, this may be the exciting cause.

*Statistics.*—It is said by Dr. Young, in his work on Consumption,<sup>a</sup>—and I dare say we may depend pretty much upon his estimate,—that one-fourth of the inhabitants of Europe die of phthisis. Dr. Young's Treatise is a sort of Bibliographia Phthisica; for the author refers to every work on the subject written previously to his own. Years ago it was calculated, that fifty thousand persons died of the complaint, in Great Britain, every year. The mortality in this country is greater than in Paris. Whereas one in *four* dies of this complaint in Great Britain, only one in *five* dies in Paris, and at Vienna, only one in *six*.

## SECTION V.—TREATMENT OF PHTHISIS.

The *treatment* of the disease must be totally different in different circumstances. Very little can be done, in general, after it has gone on to a certain length. We can then do something to alleviate suffering, it is true; but before it has occurred, unless the predisposition be very strong, I think we can do much in preventing it;—provided the person's situation enable him to follow our directions.

*Prophylactics.*—The great mode of preventing phthisis, when there is a predisposition to it, is by invigorating the body as much as possible;—by taking care that the individual shall have plenty of fresh air;—shall go out every day; have

<sup>a</sup> "A Practical and Historical Treatise on Consumptive Diseases. By Thomas Young, M. D., F. R. S."

just exercise enough, without producing fatigue; have a good portion of rest at night, and never be deprived of it; eat plenty of animal food of the best quality; and take malt liquor, or a certain portion of wine, if it can be borne. Malt liquor is the most invigorating; while, for the most part, wine merely stimulates, and in most cases does harm. The state of the mind is also of very great importance; and the utmost care should be taken to commit no excess in study, exercise, vengery, or any thing else; so as to do nothing that can do harm, and yet maintain all the functions of the body.

*Warm Clothing.*—The utmost attention should be paid to clothing. A large number of females, in this country, fall into consumption chiefly through their own fault. The poorer classes cannot dress well,—cannot be expected to take that care of themselves which they ought; because they have not the means; but the rich, and the middle classes, do every thing they can to fall into consumption. They do not wear sufficient petticoats. They wear silk stockings, and the thinnest shoes, and so walk out; or if they do not walk out thus attired, they stand on the steps of the door, and often go some yards on the pavement, before they get to their carriage. They will go from the hottest rooms without any thing about their feet. They take little sleep; have party after party every night; and then, at last, fall into a state of consumption. Neither themselves nor their friends will believe, that this want of rest and this extreme excitement have been the cause of it; but I am quite sure they have. I think I have saved the lives of several young ladies, by insisting on their following my advice of wearing plenty of flannel;—flannel-drawers, flannel-waistcoats, and high dresses. I have seen several who appeared to have every disposition to phthisis; but who, by wearing flannel next the skin, from their collar-bones to below their knees, have passed that age at which phthisis (in all probability) would have begun; and they have ultimately done well. I have taken care to add to this good living. Many wish to make themselves look slender and genteel: and therefore they starve themselves, as well as dress in thin clothing. They should take meat once or twice a-day; and an allowance of malt liquor.

*Cold Shower-Bath.*—If we can do all this, we may in many cases prevent phthisis; especially if, in addition, we can make patients use the cold shower-bath. Many cannot bear a cold shower-bath, at first; but they can bear a shower-bath *tepid*; and by degrees they can bear it *cold*. I saw a young gentleman, whose brother died of phthisis. He expectorated blood at the same time as his brother; and they appeared equally disposed to phthisis. In one, the disease ran on very fast; and he died. The survivor was spitting blood continually; and the pupil of his eye was large. I prevailed upon him to begin the use of the shower-bath; and he has done so all the winter. The result is, that he has lost his cough, spits no more blood, and is now a strong young man. No doubt, if he take care of himself, and commit no excess of any description, he will go on well. I do not know any means so powerful in “hardening” the body, as the use of the cold shower-bath; but it is to be remembered, that we cannot “harden” *every* person, and that we may kill many in the attempt. Some ladies, in order to strengthen themselves, will go out of doors in the most frosty weather; and by that means often injure themselves. We may make the most delicate hot-house plant hardy, by lowering the temperature gradually; but what will *harden* one, will *kill* another; and what will not “harden” *one* person at all, would be quite sufficient to “harden” *another*; and therefore the greatest care should be employed. Some try to “harden” themselves by having the window open; and they glory in having snow on their coverlet. Some can bear it; but a great number never could bear any thing of the kind. Still, I am sure, it is proper treatment to “harden” people as much as can be borne.

Some persons are so disposed to an inflammatory state, that it is not at all admissible to give them wine, beer, and meat. The utmost we can do is to clothe them well, make them guard against catching cold, and order the shower-bath. Some persons are so disposed to hæmorrhage,—hæmorrhage from the nose, and then hæmorrhage from the lungs,—that nothing stimulating can be allowed. There are

such cases; but I know that, in the greater number of instances, by fortifying the constitution well, and adjusting the means used to fortify it to the state of the constitution, we may do great good.

*Maintain a Uniform Temperature.*—When the predisposition is very strong, it is not only necessary that the patient should most carefully avoid catching cold, by wearing warm clothing when he is out of doors, and by avoiding all danger arising from wet feet, but the temperature of his room should be prevented from falling too low. In many cases it is necessary that the bed should be warmed; but others, not so delicate as that, should have a fire in the room, either when they go to bed, or when they get up,—once in the twenty-four hours,—for the purpose of thoroughly warming it. Some persons are so delicate,—so disposed to phthisis, that we can hardly allow them even to go out during the winter; and a certain degree of artificial temperature must be maintained in their rooms; but these are cases where the predisposition is extreme, and the debility very great.

*Removal to a Warm Climate.*—It is also of great use where there is a strong predisposition, to send patients to a warmer climate than our own,—to a thoroughly warm climate. One of the best places to which they can be sent is the West or East Indies. If that be too far, one of the best places is the south of Spain, or the south of France. Many parts to which people are sent, are very objectionable. Lisbon, for example, is very cold in the winter; and both Venice and Naples have high mountains in the neighbourhood; and therefore are not good. If we cannot send patients to the East or West Indies, the south of Spain and the south of France are certainly among the most proper places. But many cannot go even there; and for them the warmer parts of England are the only situations left. I need not mention, that parts of Cornwall and Devonshire are the most suitable; and I believe Penzance is particularly so. Nearer to London, one of the best places is Hastings. Many persons have an idea that if, instead of living in London, they go to Brompton, they are more protected from the disease; but I do not know whether there is any thing in that opinion. I have heard practitioners found fault with, for allowing their patients to live in London, and not sending them to Brompton.

But all this must be done before the disease is fully formed; for when it is once established, to send patients away from home, and thus expose them to all the misery of the journey, is not only very absurd but very cruel. It is horrible to see the grief it occasions; and the patient dies of consumption after all. It is much better, when the disease is once formed, to allow patients to remain at their own home, where there is every comfort around them.

*Iron.*—[In a letter addressed to the Royal Academy of Medicine, M. Coster announces that (from certain experiments) he hopes to prove that:—1. It is possible, even in the face of predisposing causes, to prevent the development of a tubercular diathesis. 2. Even where the formation of tubercles has commenced, their progress may, in a great number of cases, be arrested.]

The following are a few of the experiments upon which M. Coster has built his hopes:—"Two years ago he placed a number of dogs, rabbits, &c., in the circumstances most favourable for the development of the scrofulous diathesis. Thus, many of the unfortunate animals were shut up in dungeons, without light, incapable of moving; and exposed to a moist cold, by means of wet sponges which were hung up in the cages. Some of the animals placed in these conditions, were fed on their ordinary diet; others were fed with ferruginous bread, containing half an ounce of carbonate of iron to the pound. All the former became ill,—the greater part tuberculous; but not one of those fed on the bread containing iron, presented a trace of tubercles."

*Antiphlogistics.*—When the disease has formed, the treatment must be very different in different circumstances. We generally have to subdue or mitigate inflammation. There are frequent attacks of pleuritis, bronchitis, and peripneue-

monia. The pleuræ, or the lungs (including the air-cells and bronchia), or both, are commonly found in a state of inflammation. Persons are continually seized with violent "stitches in the side;" and it is necessary to take away a little blood; four or six ounces, sometimes more; or to cup the part, or to blister it. We find the blood buffed, and have to treat the case, for a time, as one of inflammation of the chest, but conjoined with little power of the constitution. In these circumstances, of course it is necessary that the diet should be low. If patients be seized with hæmorrhage, it is often necessary to treat them in the same way. It is generally necessary to bleed the patient, to some little extent; and to keep him on low diet. When there have been attacks of inflammation or of hæmorrhage, it is necessary, for some days, to pursue antiphlogistic diet; but these may all subside, and we may have recourse to nutritious diet again, or now for the first time, if we have not resorted to it before. It is right, however, not to take alarm at every pain, which a phthisical patient may have in the side; for many such attacks will go away, without any strong antiphlogistic measures; and many will go away from the application of a blister, or of a mustard-poultice, which is one of the best things. If, however, that will not remove it, it is requisite to bleed; and to treat it in the common antiphlogistic manner.

*Diet.*—Supposing, however, that there is no inflammation or hæmorrhage to subdue; and that the patient is free from pain, and has been so for some time,—then we have to support him as well as we can, and to lessen the irritation. It is often indispensable to give meat and malt liquor. Many persons in phthisis, are the better for having meat. Wine (as I said before<sup>a</sup>) has a tendency to stimulate; and therefore should not be given; but ale will often be proper. In a great number of cases, we have to consider that the patient is just in the same situation as an individual having a large abscess in the extremities; which abscess, from pouring forth an immense quantity of fluid, has exhausted him. In that case, we must allow meat and beer, in order to support the patient; and we must administer opium, to lessen the irritation; and, in phthisis, the treatment must be conducted precisely in the same way.

*Tonics.*—In this state of things it is very useful, when there is no inflammation, —no hæmorrhage, to give tonics; and of all tonics iron is by far the best. The use of what is called "Griffith's Mixture,"<sup>b</sup> is well known. There was a Dr. Moses Griffiths, who made a mixture of iron and myrrh; which is a very good form. But the myrrh is nauseous; and, after making a number of trials, I am satisfied that the iron will do as well *without* the myrrh, as *with* it. The sulphate of iron answers exceedingly well; and when it is recollected how often in this disease there is cough, out of proportion to the regular irritation that takes place, we may see that the iron may relieve the cough, even to a greater extent than it supports the constitution. I mentioned before, that many cases, which have been supposed likely to end in phthisis, have given way to the exhibition of iron.<sup>c</sup> If the sulphate purge the patient too much, or excite the pulse, we may give the sesquioxide; which is rather the milder form of the two. If we exhibit two or three grains of the iron, three times a day, patients will gain strength up to a certain point; and their cough will diminish. The relief, it is true, is only temporary; but we do good for a time; and it is our duty to protract life, without considering whether it is useful to the patient or not. We are to follow the invariable rule of saving or protracting life, whenever it is in our power to do so.

*Sponging or Bathing.*—Though we may not be able to use the shower-bath, we may do great good, and produce great comfort, by sponging the patient well with vinegar and water, cold or tepid. We may even thus check the hectic sweats, better than by any other means. When the disease is fully formed, a *tepid* bath is frequently borne, though patients cannot bear a *cold* bath.<sup>d</sup> Tepid sponging is very beneficial; and it is said to be better, if vinegar be mixed with the water.

<sup>a</sup> See Page 801.

<sup>b</sup> Answering to the "Mistura Ferri Composita" of the Pharmacopœia.

<sup>c</sup> See Page 736.

<sup>d</sup> See Page 801.

Many persons, when they have expectorated pus, have, from *tepid* sponging, come to bear *cold* sponging; and have found the greatest relief from it. That is to say, when hectic heat is upon them, they find it very comfortable; and the feelings of the patient should always be consulted.

*Anodynes.*—Among the means of lessening irritation, opium is one of the very best. I need not say, there are other things used for that purpose;—such as hyoscyamus, conium, and extract of lettuce; all of which do a certain portion of good, and are very often even more eligible than opium; because the latter may disagree. I believe the best preparation opium, is muriate of morphia, for it has seldom more than one unpleasant effect; namely, constipation; and even that is often a good thing in phthisis, because there is generally a disposition to relaxation of the bowels. A quarter of a grain of muriate of morphia, is equal to a grain of opium; and is more certain in its operation, than any other form of that drug. A solution of it is very cheap.

*Inhalations.*—We may sometimes lessen the irritation, by making the patient inhale the vapour of various drugs;—by having a vessel three parts filled with warm fluid, and making a patient inhale through it. There must be two tubes to the vessel,—so that the air may pass through the body of the fluid by means of one, while it is drawn out by means of the other. The tube which admits the air must go the bottom of the liquor,—so as to convey the atmosphere through it; and the tube to be inhaled from, must be fixed above the liquor.<sup>a</sup> The agents which have been chiefly tried are, first, a very minute quantity of iodine, mixed with hydriodate of potassa; and, secondly, chlorine. I have seen more *mitigation* from the chlorine than from the iodine; but I have never seen a case *cured*. I have used them both perseveringly; but I never saw a case of phthisis cured by these means; and I do not believe that a case ever *was* cured. I have known a single drop of tincture of iodine, put into a pint of fluid, produce great irritation; but chlorine is borne much better. The mitigation afforded by it, however, is but temporary. The mode of using it is this:—into three-fourths of a pint of water, drop four or five minims of a saturated solution of chlorine. It is best to begin with one or two minims, and to increase the quantity gradually, as the patient can bear it; but if we at last arrive at a quantity which he cannot bear, we must then desist, and go back to what he can bear. Some have recommended the exhalations of tar. Tanners, as well as butchers, are said to escape the disease; and I have employed the liquor from tan-pits, in which there is an infusion of oak-bark. I have made people inhale it; and some have found considerable relief. Others, however, have found the smell so unpleasant, that they could not go on with it. I have not used it long; but as to its curing the disease, I should imagine that is out of the question. I believe that no means whatever will effect so desirable a purpose.

*Removal of Urgent Symptoms.*—The great indication, when phthisis is once established, is to subdue inflammation if we can;—whether it occur in the form of pleuritis, or bronchitis, or peripneumonia. Besides this there is an indication, on the other hand, to support the strength by nourishing food and tonics; and a third

<sup>a</sup> The particularity of this description is by no means uncalled for; and a medical man, when he orders a patient to inhale vapours, must give his personal attention to the manner in which it is performed, if he wishes to have his intentions efficiently carried out. On one occasion, in a large hospital, when a patient with ulcerated sore-throat had been ordered to inhale steam, I found him with the tin-inhaler comfortably tucked under the bed-clothes, with a cork stuffed into the air-tube. The consequence of this was, that the patient was obliged to remove his mouth from the instrument after every inspiration; and, after all his laborious efforts, the supply of steam was very insufficient. The nurse (in every respect an excellent one), on being questioned as to the use of the cork, very naturally replied that it was “to keep in the steam;” and added, that she had been in the hospital eleven years, and never saw an inhaler used in any other way. There is nothing surprising in all this. Nurses are not expected to understand the principles of pneumatics. On instituting an inspection of the other inhalers in the hospital, every one of them was found duly provided with a cork.—*Dr. Rogers.*

indication is to subdue irritation by narcotics. It is necessary to attend to another indication;—the removal of urgent symptoms of various kinds.

We continually find a person sweating so profusely, that his strength is thereby greatly diminished; and this may often be subdued by washing him all over with tepid vinegar and water, several times a-day; or by the exhibition of sulphuric acid; and sometimes, again, by acetate of lead. We also frequently have to subdue another evacuation; which is purging. This, of course, is to be accomplished chiefly by astringents and opium. Unfortunately, the more we subdue one evacuation, the more we increase the other. Frequently, when we check the sweats, the purging becomes more intense; so that while lessening the sweating by tepid ablution (with vinegar and water, for example) it is safe to give astringents, lest diarrhœa should suddenly begin. Diarrhœa is one of the most tiresome symptoms in consumption; and very frequently astringents and opiates do not succeed in arresting it,—on account of the inflammatory state of the mucous membrane; and yet the patient is too weak to bear leeches; and suffers so much altogether, that it is very painful to apply blisters. In many cases, fomentations or poultices of bran applied to the abdomen, will be as good means as can be adopted. Frequently the largest doses of opium (such as will produce great stupor), and the largest quantity of astringents (such as almost overload the stomach), have no tendency to check the diarrhœa. For a long time they may succeed; but at last, in most cases, the diarrhœa becomes so severe and obstinate, that they lose their effect. A remarkably large quantity of astringents and opium may be given, with little or no benefit. However, we must do our best; and astringents and opium are certainly the best modes of checking the diarrhœa. Frequently there is ulceration of the intestines; and, among the astringents, sulphate of copper answers better than any other. It has a tendency to produce sickness; but that may be subdued by hydrocyanic acid. If we exhibit sulphuric acid, it is generally necessary to guard it by laudanum; for its acriminious qualities, when given by itself, tend to increase the affection of the bowels.

*Empirical Remedies.*—Certain remedies have been boasted of as being capable of curing consumption; but there is no reliance to be placed on any of them. We are continually asked about the propriety of Iceland-moss, and things of that description. There is no harm in them. On the contrary, they are good so far as they are nutritious and bitter; and are very proper things to be given; but there is no hope of saving a patient by them. It has been stated, that a large quantity of vinegar has cured the disease. Some persons give, in the course of twenty-four hours, about seven ounces of vinegar mixed with seven ounces of water, and sweetened with two ounces of refined sugar; but fair trials have been made with it without success. The balsams have also been recommended; but sometimes they heat the system exceedingly, and increase the inflammatory state. Myrrh has been recommended by some; but I believe it does no more good than any other tonic. We have also had the sulphate of copper strongly recommended; and it does alleviate the symptoms. I think I have seen it, when guarded by opium, not only check the diarrhœa, but diminish the copiousness of the expectoration; but it has no specific virtue. Some have recommended us to give a person an ague; but so many persons who have ague die of consumption, and consumption is so common in aguish parts, that there is no reliance to be placed on this; and it would be great cruelty to give a person another distressing disease (such as ague), for the mere chance of doing good once, perhaps, in a thousand cases. Little more can be done than to lessen inflammation, support the strength, lessen irritation, and subdue urgent symptoms; for, after all that can be done, persons generally die of the complaint. The disease goes on progressively, and we can lessen suffering; but that is all; although, as I have already said,<sup>a</sup> the disease may, no doubt, be *prevented* by great care.

*Elongation of the Uvula.*—Symptoms arising merely from elongation of the

<sup>a</sup> See Page 800.

uvula, have very often been mistaken for real phthisis. This is a little point worth knowing. When the uvula is elongated,—hanging from the pharynx,—it sometimes produces constant cough; and this leads to a constant expectoration of mucus, and in some cases to emaciation. It happens, now and then, that extreme emaciation has been the consequence of an elongated uvula. Patients, from the constant cough and expectoration, have become emaciated; the tongue has become white; flying pains have taken place in the chest; loss of appetite has occurred; the pulse has become small and unequal; a pain has been felt in the larynx, from constant efforts being made to expel the mucus;—all of which symptoms have arisen from an elongated uvula: and therefore, whenever we are consulted by a patient labouring under these symptoms, it is right to look into the pharynx.

*Treatment.*—The complaint may be promptly remedied by snipping off the lower half of the uvula, with a pair of scissors. The pain is but momentary; there may be a little bleeding; but the operation is perfectly safe.

It is very seldom that such severe symptoms will occur as to be mistaken for phthisis; but sometimes such a circumstance has taken place. Very often, however, persons have a tiresome cough, which has been mistaken; so that blisters have been applied to the chest, when the symptoms have arisen from nothing more than an elongation of the uvula. With regard to local applications, the best are those which unite astringent with stimulating properties; but in cases where these fail, the operation of curtailing the uvula should be had recourse to.

[There are few subjects within the range of medical science, that modern investigation (powerfully aided by the stethoscope) has more strenuously sought to elucidate, than that of which we have just completed Dr. Elliotson's masterly exposition. The fearful ravages of pulmonary consumption; the insidious nature of its approach; the rapacious cruelty with which, as if in bitter mockery of our dearest sympathies, it loves to select the young and the beautiful for its victims; and the little avail hitherto attending our exertions to wrest the prey from the merciless spoiler;—all this has combined to impart to its investigation no ordinary share of interest.\* Nor have the difficulties attending the pursuit caused the zeal of its followers to relax; for obstacles in the path of the real votary of science, instead of paralyzing exertion, only lead to greater effort. It is a heartless apathy, equally unworthy of the philanthropist and the physician, that can look at the mass of disease yet unsubjected to the control of medicine, without humiliation at its extent, and anxiety for its diminution! And who shall say that its diminution, nay its final extinction, may not ultimately be accomplished? There are depths in science, and in medicine too, of which our present means of investigation only serve to show the profundity; but who will venture, either in the one case or in the other, to set bounds to the future advancement of knowledge? With the recollection of what has been already done, is there one in the whole range of diseases, against which the power of medicine shall be declared for ever unavailing? A conquest so noble as this, however, is not to be attained at once. It must be the result of patient and laborious investigations; of multiplied and varied experiments; of impartial and repeated observations. We must be content to ascend the steps, if we would ever attain the summit. It is on this account that every devoted student of medicine must hail, with pleasure, the light which has been thrown on this and kindred subjects, by the French school; and to those who have devoted their lives to an unflinching warfare with disease and death, and to the grateful task of soothing the pangs of suffering humanity, will be adjudged, by every properly constituted mind, a higher meed of applause, than to heroes and conquerors the most successful and renowned.]

\* Various points of interest relative to this subject, are discussed by Dr. Graves, in two lectures which form part of one of his clinical courses;—courses distinguished no less by attractive vivacity of style, than by intrinsic excellence of matter. See the "London Medical and Surgical Journal," for March, 1833. (Nos. 61 and 62; Volume 3; Pages 230 and 262.)

† Dr. Rogers.

## CHAPTER XI.

## DISEASES OF THE PLEURA.

## SECTION I.—ACUTE PLEURITIS.

I now proceed to consider diseases of the pleura; and, in the first place, the most common affection of it,—*inflammation*.

*General Symptoms.*—When the pleura is inflamed, there is (of course) pyrexia. If the inflammation be idiopathic,—if it be consequent on some local irritation, it usually begins with shivering; and is followed by quickness of the pulse, and all the symptoms of pyrexia. The pleura is a serous membrane; and therefore, in most cases, we have a firm hard pulse;—not invariably, but generally. Then, as to the *local* symptoms, we have almost always severe pain,—an acute, stabbing, sharp pain;—the least attempt at a deep inspiration augmenting this pain exceedingly. This pain is not increased on the *least* pressure. We may press the integuments down upon the ribs, without aggravating it; and we may press moderately between the ribs; but if we press very firmly between them, and still more firmly upon the ribs themselves, we (of course) press upon the pleura, and then the pain will be increased. In severe cases there is extreme pain, so that hardly any pressure can be borne; and I have known persons unable to lie on the side, on account of the pressure exerted by the part against the bed.

*Distinguished from Rheumatism.*—A case must be very severe, for pain to be felt on *slight* pressure. In truth, we may generally distinguish pleuritis from rheumatism of the muscles of the chest, among other means, by this;—that in the latter case the least touch causes pain and soreness;—such a pressure as will not affect a patient labouring under pleuritis;—pressure on or between the ribs, and at the back or front of the chest. In acute rheumatism, for the most part, there is profuse sweating;—such as there is not in pleuritis; but there is not, in rheumatism, that general disturbance of the constitution, which occurs in pleuritis. In pleuritis, the whole constitution is very much disturbed; and there is not, by any means, that severe pain which there is in rheumatism. In general, we can make out the difference of the cases very well. The pain, in pleuritis, is only felt at the lowest part of the chest;—or, at least, low down in the chest;—not in front, nor at the back; but towards the side. I suppose the disease has had its name (“*pleuritis*”) from the pain being observed to be situated in the side (*πλευρα*); and not from the pleura being inflamed.

The respiration is rapid in this disease, because the patient cannot make a deep inspiration; and, to compensate for the want of depth, he breathes the more quickly. The pain is increased by coughing, and by speaking. Sometimes, on account of its severity, patients cannot speak at all. In general, we make out the nature of the disease sufficiently, without listening to the chest. This affection is one of the best marked of any with which I am acquainted. There can be no difficulty, except in distinguishing it from rheumatism; and, in general, by attending to the points just referred to, no difficulty will be met with, even on that head.

*Varieties in the Symptoms.*—The seat of the pain will sometimes vary in the course of the disease. It will sometimes cease on one side, and be felt by the patient on the other; and it is said that, now and then, the pain is not felt in the part which is found inflamed after death. The pain is felt in the opposite side during life; and opposite to that in which we find marks of inflammation after death. It is said, though I do not recollect seeing such a case myself, that sometimes no pain has been felt at all; and the practitioner has been surprised to find, at the autopsy, violent marks of inflammation. Usually the patient lies best on the oppo-

site side; but sometimes he can lie more easily (or lie *only*, indeed) on the affected side. The cough which attends this disease is usually dry, and not very frequent; and sometimes it is altogether absent.

*Auscultatory Signs.*—On listening to the affected part, we generally find less respiration there, than there should be. The part is not much expanded in respiration. The ribs, at that part, do not move so much as in other parts of the chest that are healthy. Less respiration occurs there; and, on that account only, there would be less respiratory murmur; but there is sometimes considerable effusion of lymph, or of serum; and that, of course, will obscure the respiratory sound. After a time, effusion takes place in a decided manner; and then we have a dull sound upon percussion, and no respiratory murmur is heard at the part. There is no *crepitous* rattle heard, as in pneumonia;<sup>a</sup> and no *sonorous* or *sibilous* rattle, as in bronchitis;<sup>b</sup> and therefore—with this absence of sound, and the acuteness of the pain—there is in general no difficulty in saying, that the patient is labouring under inflammation of the pleura. Now and then, pleuritis is united with pneumonia and bronchitis; so that we have the crepitous rattle as well as acute pain; or we may have a sonorous and sibilous rattle; but the acute pain, which is unknown in pneumonia and bronchitis, sufficiently shows that those affections are complicated with inflammation of other parts.

*Ægophonism.*—When effusion takes place, we may always ascertain it to a certainty by the presence of ægophony. Sometimes the patient loses his pain, and may even say he is a great deal better; but notwithstanding that, on listening to the chest, we may ascertain that he is in considerable danger. Indeed, in such cases, we may be satisfied,—from the quickness of the respiration, or the difficulty of it,—that all is not going on well. But if, in every case of pleuritis, we make a point of examining the chest by the ear, we may ascertain to a nicety when effusion takes place, and to what extent it has occurred. In cases unattended by danger altogether, this effusion may occur; although a person who does not use his ear, would not know that it existed. When effusion is present, there is a dull sound on percussion, and a want of respiratory murmur; and besides that, if the effusion be inconsiderable, we have in most cases a peculiar phenomenon; which is called “ægophonism”<sup>c</sup> (from *φωνη*, *sound* or *voice*; and *αἶς*, *a goat*);—the sound of a goat. When once heard, this sound can never be mistaken. It is a sound which but few persons have heard; because, in general, people do not listen to the chest in this disease; and when it is heard, it is only in a *moderate*, not in *great* effusion. The symptoms at large are not severe at the moment it is heard; and therefore those who are not in the habit of using their ears, in this particular disease, do not think it worth while to examine the chest at that period. We hear it best by applying the stethoscope firmly to the chest; and then applying our ear lightly to the stethoscope. The voice does not run through the tube, as in pectoriloquy. It does not, by any means, take place to the same degree. It rarely, indeed, enters the tube at all. There is no difficulty in learning these signs. Laennec says he noticed it in every case of pleuritis that he examined, for five years preceding the publication of his second edition.<sup>d</sup> Where the effusion is very moderate indeed, then it is not sufficient to produce the sound; and if it be excessive, the phenomenon cannot take place at all. Laennec says he has observed it, where there did not exist in the chest above three or four ounces of fluid.<sup>d</sup> It will occur, not merely when there is *serum* effused in the pleura; but also when the serous membrane pours forth *pus*; as it sometimes will. Altogether it is a variable symptom; because it can only occur when the effusion is moderate.

*Cause of Ægophonism.*—This phenomenon is explained, by Laennec, to be owing to the compression of the bronchial tubes by fluid, conjointly with the transmission of the sound of the voice through a thin *layer* of fluid. If the layer be very thin, it is not sufficient; for the sound must pass through a certain body of fluid;

<sup>a</sup> See Page 753.

<sup>b</sup> See Page 739.

<sup>c</sup> See Page 713.

<sup>d</sup> Laennec, on Diseases of the Chest; translated by Forbes. “Preliminary Essay,” Chapter 4; Section 2; Subdivision 3. (Third Edition; Page 42.)

and, indeed, a very thin layer of fluid would not be sufficient to compress the bronchial tubes. It must reach a certain amount, both in order to compress the bronchial tubes, and to be the medium of this sound; for if there be great effusion, the bronchial tubes are so compressed, that there is but little air in them; and then the sound cannot be heard. Whether Laennec's explanation is correct, I will not pretend to say. By changing the level of the fluid, we change the seat of the ægophonism. If the patient be upright, it will be of course over the highest portion of fluid; but if the patient be lying down, then it is heard where the layer of fluid is the thinnest.

*Morbid Appearances.*—If we inspect the part after death, we find nothing more than I mentioned, when speaking of inflammation of serous membranes in general.<sup>a</sup> Sometimes there is diffused redness; sometimes there is a *striking* redness, and an effusion of lymph on or within the pleura; and sometimes there is serum, occasionally quite clear, but for the most part turbid, and of a yellow colour, with more or less flakes of lymph swimming in it.

*Causes.*—The disease arises, in almost every instance, from cold and wet. It will sometimes arise from a local source of irritation; for example, from wounds, from the effusion of substances into the pleura, or from ulceration of the part; but by far the most common cause is the application of cold.

*Treatment.*—Upon the treatment I need not dwell. It is nothing more than that for any common inflammation.<sup>b</sup> Bleeding, mercurializing, starving, and purging, will cure it;—just as easily as any other inflammation.

*Blood-letting.*—[The most desirable object is to destroy the inflammation at its very onset, before the signs show that the effusion is considerable. For this purpose, the most effectual remedy in severe cases is a full general bleeding, carried (if possible) to such an amount as to remove all pain on full inspiration; or, if there be little or no pain, until all hardness of the pulse ceases. This should be followed by free leeching or cupping of the affected side. We<sup>c</sup> think leeches generally preferable; but they should not be applied sparingly; and they should be immediately followed by a large warm poultice covered with flannel, or by a succession of warm dry napkins. These depletory measures must be repeated, if within a few hours the pain return, or the pulse resume its hardness. Of internal remedies, those are the most useful, in the first instance, which assist the blood-letting in producing an impression on the circulation; especially brisk purgatives, containing mercury and antimony; which act fully on all the secretions. Calomel and James's powder, followed by an active draught consisting of salts and senna, generally answer best. Tartarized antimony is less effectual in this than in other inflammations of the chest: it may do harm if it excite vomiting; but in doses short of that effect it may prove useful.

*Mercury.*—It commonly happens that such measures take off the edge of the disease without destroying it entirely; or, at least, without removing its products; which must be a work of time: and although the pain, dyspnea, and cough be much relieved, they are not removed; and the physical signs show, that effusion has taken place to a greater or less extent. In these circumstances, the proper means are those which promise to fulfil both indications;—to reduce the remaining inflammation, and to promote the absorption of the matter already effused. The most powerful of these is mercury; which may be combined with ipecacuanha and opium;—to lull the pain, and to prevent the calomel from passing off too freely by the bowels. These remedies should be given in pills every three or four hours; and to them may be added digitalis or colchicum in a saline mixture, with an excess of alkali;—to keep down the action of the heart and arteries, to determine to the kidneys and skin, and to lower the inflammatory condition of the blood. The beneficial influence of mercury is sometimes apparent when it does not affect the gums, especially in young subjects;—its operation being only manifest on the hepatic and alvine secretion; which is green, dark, or high-coloured,—from different

<sup>a</sup> See Page 108.

<sup>c</sup> Dr. C. J. B. Williams.

<sup>b</sup> See Page 118.

conditions of the bilious matter in it: but in most cases the gums exhibit the effect of mercury before these secretions are produced.

*Lecches and Blisters.*—Venesection can seldom be repeated with much advantage after the first few days; unless on the occasion of a fresh access of pain, or other symptoms which denote the renewal of acute inflammation. Occasional leechings continue to be useful; but, after the inflammatory fever has been reduced, the most effectual external remedies are blisters; which should be large, and not left on too long; from six to eight hours is generally time enough to make them vesicate without inflaming the tissues too deeply, or irritating the system by the absorption of their serous discharge. Where the effusion is abundant, a succession of blisters will be necessary; or they may be varied by a suppurating counter-irritant;—such as the tartar-emetic ointment or solution.

*Diet and Regimen.*—The diet must be of the most spare kind, in the early stage of acute pleurisy; and the patient should remain as quiet as possible in bed. But when the inflammation is subdued, sitting up, and (if the strength will permit it) using a little exercise about the room, will be beneficial in promoting the absorption of the fluid.

In limited varieties of pleurisy,—such as those of a mild or partial kind, those excited by tubercles, and those which occur in combination with typhoid or asthenic symptoms,—the antiphlogistic measures above described must be reduced to suit the nature of the case, and the amount of the general strength. Circumscribed pleurisies may sometimes be removed by cupping or leeching only; and in conditions of the system depressed by febrile or other morbid poisons, or reduced as in phthisis, blisters, or sinapisms may be the only antiphlogistic means which can be borne. In continued fever, besides these external means and the usual salines, mercury in combination with opium is, according to our<sup>a</sup> experience, the most appropriate remedy.<sup>b</sup>]

## SECTION II.—CHRONIC PLEURITIS.

Pleuritis is sometimes a *chronic* affection; and here it is that the particular sign called “ægophonism”<sup>c</sup> is essentially serviceable. When pleuritis occurs in a chronic form, it is every day mistaken for phthisis. I have seen instances of this over and over again. Sometimes the *acute* form of the disease degenerates into the *chronic*; but more frequently the latter is a very insidious affection; and creeps upon the patient slowly.

*Symptoms.*—The general symptoms so much resemble consumption, that the patient is supposed to have gradually fallen into that affection; for this chronic form of the disease is frequently attended by no pain, or only by *obscure* pain; and yet the patient has pyrexia, cough, and expectoration. He will become hectic, and waste away; the pulse will be constantly quick, and he will die. On opening the body, a large quantity of pus will be found in the pleura; while the lungs themselves, perhaps, are entirely sound. Very frequently, when chronic pleuritis exists, tubercles exist in the lungs at the same time; but frequently they do not; and, at any rate, if they do, it is very common for pleuritis to have been the sole cause of death;—none of the tubercles having proceeded to ulceration.

*Adhesions; Effusion.*—In this chronic form of pleuritis, adhesions are not formed to any great amount. In the *acute* form, the effusion leaves adhesions. Sometimes the whole side is adherent;—the “pleura *pulmonalis*” to the “pleura *costalis*,” but in this *chronic* form the collection is often altogether, or the greatest part of it, pus; and any adhesions that form, are frequently slight portions of lymph that have been effused. They are so soft, that they are not capable of becoming organized; but, as they are mixed with serum, we find (after death) that

<sup>a</sup> That of Dr. C. J. B. Williams.

<sup>b</sup> “Library of Medicine,” Volume 3; Pages 123 and 124.

<sup>c</sup> See Pages 713, 803, and 811.

the two substances are united; or, at least, that the one is mingled with the other. This fluid—this turbid serum, or *puriform* serum, or this absolute pus—augments daily, till the lungs are compressed towards the spine, and towards the mediastinum; and sometimes they are so reduced, that, on a careless examination, they have been said to have disappeared altogether.

*Empyema.*—Sometimes the affected side of the chest grows large; and if it be the left side in which the disease resides, the heart is pushed to the right;—so that it beats on the *right*, instead of the *left* side. The disease is then called “*empyema*,” if the fluid be pus; but it makes no difference whether it be pus or serum. In these circumstances, the ear may not be necessary in order to recognise the disease; for the side is visibly increased in size. It appears, to the eye, to be larger than the other; and, on measuring it, we find one side of the chest half an inch, perhaps, or an inch, larger than the other. Sometimes we can discover fluctuation,—just as in other instances of a collection of pus; but now and then there is no enlargement of the chest, and no fluctuation to be felt.

*Signs afforded by Auscultation.*—When effusion takes place, there is a dead sound on percussion; and no respiratory murmur is heard. This is the natural result of the part being no longer filled with air, but with pus; which has driven the lung aside or upwards, and compressed it below. When a lung has become solid from air, we have this same auricular phenomenon. If the lung become solid from inflammation,—if the substance be converted into something like liver, so far as the solidity is concerned,<sup>a</sup>—we must have a dead sound on percussion, just as if fluid were there. No more air exists in the lung when it has become solid, than when fluid abounds in the chest; and in these circumstances we have equally no respiratory murmur; because the lung, being solid, is unfit for its functions. But when a lung thus becomes solid from inflammation, it becomes so solid throughout, that there is no respiratory murmur at the *root* of the lung; for that part is equally inflamed with the rest; whereas when the dull sound of the chest, and the want of respiratory murmur, arise from a collection of fluid, it rarely so compresses the lung, but that we may hear respiration at the posterior part; that is to say, along the sides of the spine, about three fingers’ breadth from the vertebral column. Respiration also continues there when fluid is collected. However great the effusion may be,—even if the lungs be so compressed as to be found with difficulty after death,—still I believe that the respiratory murmur is heard at the back and root of the lungs, in the situation I have just stated. This murmur, too, is heard before the effusion is very considerable; and it is heard for a length of time under the clavicle, at the highest part of the chest;—before the collection of fluid mounts so high. When the want of a hollow sound on percussion, and the want of the respiratory murmur, arise from the lung becoming solidified through inflammation, we may very rapidly cease to hear the respiratory sound under the clavicle. The inflammation may so quickly solidify the lungs, that we may hear no respiratory murmur on either side of the spine; because all parts of the lungs may be inflamed.

*Ægophonism.*—Ægophonism certainly does now and then occur; but still it is to be remembered, that if the fluid fill up the side of the chest, or nearly so, we cannot expect this phenomenon. It is only in a *moderate* collection that this sign is present; and therefore a person may have the pleura full of pus without it; but if we have attended the patient from the beginning of the complaint, and have been in the habit of noticing all the symptoms to be learned by the ear, in conjunction with the general symptoms, it is easy to find that ægophonism has appeared and disappeared; and we know it has disappeared, not from an *absorption* of the fluid, but from an *augmentation* of it, because percussion of the chest gave a dull sound, just in proportion as the ægophonism declined.

The part of the chest where we should first listen for ægophonism, is from about one to three fingers’ breadth from the lower angle of the scapula, towards the nipple. The reason why it is most frequently heard there is, that the fluid generally

accumulates below that part; and if the whole lung be covered with effusion, still the thickness of the body of the fluid is always less at the posterior part. We can hear this phenomenon here, when we can hear it nowhere else; because the fluid cannot accumulate so extensively in this situation, as in other parts. After the phenomenon has declined in the *front* of the chest, from the great accumulation of fluid, it may still be heard at the *back*, in the particular part I have indicated.\*

*Displacement of the Liver.*—In mentioning that the accumulation of fluid in the left pleura, sometimes pushes aside the heart,—so as to produce the extraordinary phenomenon of the heart beating on the right side,<sup>b</sup>—I might have stated, that before auscultation was known (but after percussion had been introduced to the medical world, and treated with neglect in this country), I saw a case that puzzled me completely. In a case of this disease, the liver was so pushed down, that it was felt below the navel; and I, being young in practice (though, however young a practitioner might be now, he could not make such a mistake), had no idea of the nature of the disease; but supposed that the man had an enormously enlarged liver; and so did every body else that saw him. The man had a very enlarged abdomen. After death, the liver was found perfectly healthy; but, like the heart in other cases, it was not in its “right place.” A vast accumulation had taken place in the right pleura; which actually pushed down the diaphragm, and the liver along with it;—so that the case was completely misunderstood. If auscultation had been then devised,—if all the phenomena that are known *now*, had been known *then*, the matter would have been very clear. We should have ascertained that there was no enlargement of the liver, from this circumstance;—that there must have been a dull sound on percussion, all up the right side of the chest; and, on listening for respiration on the right side, there would have been none heard. It would have been perfectly clear, that the right side of the chest was occupied with something else instead of air; and if the case had been observed throughout, of course there would first have been noticed ægophony; and afterwards it would have disappeared;—so that no mistake could have been made. An operation might have been performed, and the man might have recovered; but, as it was, he died. There was a large collection of liquid in the right side of the chest; and every one was quite surprised to find it there. I was not at the inspection; but such was the result. An accumulation in the right side of the chest, therefore, may push down the liver in an extraordinary manner;—just as accumulation in the *left* side, may push aside the heart. Even now, cases of chronic pleuritis are every day mistaken for phthisis.

*Dyspnœa not very great.*—In this chronic form of the disease, as the accumulation takes place slowly, respiration is not so difficult as might be imagined. The other side of the chest gradually does more and more duty; and the patient feels the inconvenience increase so gradually, that it is not such a source of distress to him as we should imagine. In *acute* pleuritis, when the effusion is very considerable, respiration is necessarily rapid;<sup>c</sup> and there we have infinitely more difficulty of breathing, than if the same quantity of fluid were effused in a *chronic* form. There is nothing more than an instance of a general fact;—that when any thing peculiar comes on slowly, and is increased moderately, it is not productive of half the excitement, that it would be if it came on quickly.

*Effect of Compression on the Lungs.*—When the fluid has thus compressed the lung, although nature may cause its absorption, or although a medical man may occasion its escape by an operation, it is possible that the lungs may never expand again; and this want of expansion may occur, either from the great compression they have undergone, or from the production of such firm adhesions, that they are effectually bound down. Inflammation may not only have induced the accumulation of fluid; but may have produced such an effusion of fibrin, as to form firm bands,—binding down the lungs; and, from either of these circumstances, the lung may never recover its elasticity. Laennec declares that, on inspection, he has

\* See the last Paragraph but one.

<sup>b</sup> See Page 811.

<sup>c</sup> See Page 807.

uniformly found these firm adhesions; and he calls them “fibro-cartilaginous;”—not “fibrous,” as we generally see adhesions; but “fibro-cartilaginous.” However, as the lungs have been known to expand again in some degree; and as the chest, which was sunk in, in consequence of the compression of the lungs, has in some degree recovered its form,—we can hardly suppose that the lungs, in every case, are prevented from expanding merely by adhesions. Of course, if the lungs do not expand, the chest will become flattened on the sides, from the pressure of the air; but it has been known that the chest, after it has become flattened, has enlarged again,—from the lungs having recovered their powers; and if the want of expansion in the lungs, for a great length of time, arose from fibro-cartilaginous bands, it is not likely that they would ever have yielded, so as to allow of the expansion of the lungs again. The extreme compression of the lungs, seems to me to be quite a sufficient cause for the want of their subsequent expansion, without having recourse to the supposition that, in every case where they do not expand again, there must be firm adhesions. The whole lungs are so compressed,—so squeezed together, and become so fixed, that they resemble muscles;—muscles with fibres too minute for detection. The colour is either red or gray.

*Contraction of the Chest.*—If the lung has been so compressed that it will not expand, and the fluid has been absorbed or let out, and no more has formed, the ribs on that side fall, and lie more closely together than they should do. The shoulder, on that side, falls below the other; and the muscles (especially the pectoral) waste,—both as to breadth, and as to length. The muscles waste in proportion as the side becomes contracted; and they are found, on actual measurement after death, to be diminished; and still more do they appear to the eye to be diminished. Even the spinal column at length inclines, in some cases, to the opposite side. Most practitioners must have seen instances of persons, with their ribs lying closely together on one side; with the shoulder depressed, and the spinal column bent to the other side. The nature of such cases, however, was not understood, nor were the general phenomena of the case itself well described, before the appearance of the first edition of Laennec’s celebrated work.<sup>a</sup> I recollect, very well, having had an individual pointed out to me, as a decided proof of the power of hydrochlorate of lime in scrofula and phthisis. After suffering very long from pectoral complaints, and being put under the long exhibition of muriate of lime, the man recovered his health; but one side of the chest was manifestly smaller than the other; and he was shown to every body as a man who had long had phthisis; but in whom all the ulcers had healed up, in consequence of his having taken the remedy just mentioned. It was considered that the lung had wasted away from ulceration; and the contraction of the side of the chest, was thought a sufficient proof of it; because he had continually expectorated from irritation of the bronchia. I supposed, not knowing better,—for nobody knew better in those days,—that this was actually the case; and therefore did not attempt to deny it. There is no doubt, however, that this was not a case of phthisis at all; but that it was a case of chronic pleuritis, in which great effusion had taken place; which effusion had afterwards been completely absorbed, by the power of nature; and the lung had never been able to recover itself from its compressed condition. There is, in Laennec’s work, a drawing of an individual, with one side of the trunk lower than the other;<sup>b</sup>—through the falling in of the chest, in the manner I have now described.

*Cause of Contracted Chest.*—Laennec considers, that when a case of this description is well marked, it arises from that form of pleuritis, which is attended by hæmorrhage into the pleural cavity.<sup>c</sup> I mentioned, when speaking of hæmorrhage, that mucous and serous membranes will sometimes produce an effusion of blood;<sup>d</sup>

<sup>a</sup> See Note to Page 706.

<sup>b</sup> See Plates 6 and 7 in Dr. Forbes’s Translation.

<sup>c</sup> Laennec on the Chest; translated by Dr. Forbes; Part 1; Book 3; Chapter 1; Section 6. (Third Edition; Page 459.)

<sup>d</sup> See Pages 136 and 137.

though we cannot tell the reason; but sometimes it is the case. This sometimes happens in the case of the pleura. There is, however, no proof that it *always* results from hæmorrhagic pleuritis. Sometimes it arises from that source; but sometimes the fluid, when let out, has proved to be mere pus, without any admixture of blood; and yet contraction of the chest has occurred;—just as where blood has been let out in conjunction with the pus. If it occur more frequently (as Laennec says<sup>a</sup>) after hæmorrhagic pleuritis, and if the dense fibro-cartilaginous bands (formed by a cohesion of the fibrin in the blood effused upon the costal pleura) were always discovered in contraction of the chest,<sup>a</sup> still I should not regard the thickness of these bands of fibrin as the *cause* of the contraction; but as *effects*, no less than the contraction itself, of the inability of the compressed lung to expand again.

Bloody fluid, just like pus, is not so rapidly absorbed as mere serum. When blood is effused, the lung is irrecoverably compressed, by the duration of the pressure; and, from the slow manner in which the elasticity of the chest, and the pressure of the atmosphere,—resisted as they are by the natural structure of the chest,—can bring down the side to the flattened lung, a space probably exists, greater or smaller, for some time. Laennec, indeed, seems to contradict himself; for he says he is of opinion, that contraction of the chest may be found, in an equal degree, after the disease has produced merely cellular adhesions; so that, in some parts of his work,<sup>b</sup> he seems to give up the opinion, that the inability of the lungs to recover always arises from these firm fibrous cartilaginous bands. He also allows, in another part of his work,<sup>c</sup> that the contraction is owing, not to the adhesions themselves, but to their slow formation. The more slowly these are formed, the less chance will the lung have of expanding. He says<sup>c</sup> that if the effusion be copious, and consequently the resolution of the pleuritis slow, the contraction is evident long before the complete absorption of the fluid; but he says,<sup>c</sup> that the more rapid the absorption, the less chance is there of contraction; since the longer the lung is compressed, the greater is the loss of its natural elasticity. In short, Laennec himself does allow,<sup>c</sup> that the continuance of the compression, through the effusion, is the cause of the inability of the lung to recover itself. I myself have frequently opened persons, in whom the lung has never recovered itself; and yet there have been no fibro-cartilaginous bands, or bloody fluid; so that the long continuance of the compression, appeared sufficient to explain the immobility of the lung.

*Period at which Contraction Commences.*—When the chest contracts, in chronic pleuritis, the diminution may begin at an early period of the effusion; but may not be perceptible for months. Of course it can only be a certain degree of contraction of the chest that is observable; and those persons who are not in the habit of examining patients with the eye and with the hand,—who consider those as mechanical means, fit only for the surgeon;—those who are not in the habit of making patients undress, and are not accustomed to handle them, except to feel the pulse;—such persons will, of course, be ignorant, for a great length of time, of contraction of the chest. It may go on till the patient makes the discovery, and announces it to his medical attendant.

*Auscultatory Signs of Contracted Chest.*—When the chest is contracted,—when fluid no longer exists, but the lung is compressed, and the thorax goes down upon it,—then there is a dull sound upon percussion;—just as when pleuritis existed; and sometimes we have not only a *dull* sound, but a true *fleshy* sound;—the same sound as if we struck the shoulder or the thigh. But notwithstanding this dull sound, the respiratory murmur is heard a little. Probably, there will be

<sup>a</sup> See Pages 136 and 137.

<sup>b</sup> See Dr. Forbes's Translation; Part 1; Book 3; Chapter 1; Section 6. (Third Edition; Page 462.)

<sup>c</sup> See Dr. Forbes's Translation; Part 1; Book 3; Chapter 1; Section 6. (Third Edition; Page 463.)

no respiratory murmur at the lower part of the chest, where the effusion had taken place first, and must have ceased the last:—for, of course, it is to the lower part of the chest that the fluid will gravitate at first, as well as at last; but respiration may be heard faintly at the upper part.

*Usual Termination of Chronic Pleuritis.*—When the inflammation has ceased, and the effusion to which the inflammatory state gave rise has ceased, the walls of the chest are flattened down proportionately to the contracted dimensions of the lung; and nature has effected a cure, exactly in the same way that a surgeon effects a cure of hydrocele;—by adhesion. In the case of a hydrocele, there is a serous membrane; and when it is inflamed by an injection, fibrin is poured forth, and also serum. The serum is at last absorbed, but the fibrin blocks up the cavity altogether; and that is exactly the state of the parts in the cavity of the chest. When nature has effected a cure, in the way that I have now described, the person is more or less deformed for life; but suffers little inconvenience. The general health may be excellent. Laennec mentions the case of a distinguished surgeon at Paris, whose chest was contracted after pleuritis, which took place in youth; and in whom percussion, when Laennec wrote, gave a dull sound at the lower and lateral parts of the affected side of the chest; and the respiratory murmur was weaker there, than on the opposite side; but this surgeon had a strong voice; and contrived to lecture once, or even twice a-day, for an hour at a time, without any inconvenience.\*

*Treatment of the Empyema.*—In this particular form of the disease, the making of a correct diagnosis is very important; because we may render a patient essential relief. We may save life; and in those cases in which we cannot save it, we may protract it. It was only a few years ago, that I had a case of this description, in a young child almost at the breast. The heart was pushed so much to the right side, that it was pulsating there; and, the nature of the case being perfectly clear, a lancet was plunged into the left side of the chest two or three times; and the child fortunately recovered, and is alive now. An operation is always safe in these cases. If the collection should point at a particular part, that is the spot at which we should make the opening; but if it do not point, then we should puncture between the eleventh and twelfth ribs. If there be any doubt about the case, I should advise the use of a needle invented by Dr. Thomas Davis. He had a large needle made with a groove; which we may introduce without any danger. When it is plunged in, if fluid exist, a drop will form near the end of the needle. Whether there be water present, or pus, it will escape to a certain extent; and if a drop of fluid come, we may be sure of the nature of the case. A small trocar may then be passed in; and we may thus draw off the fluid. It will be right not to draw off much at a time;—to draw off only what we consider to be a third or a half of what is there,—according to the size and age of the patient; and we may continue to draw it off at different times, till the chest is completely emptied. It was the custom of the late Dr. Thomas Davis,<sup>a</sup> I know, to pass in a piece of hollow bougie; and to let it remain there. The end of the bougie must be bent down, and fastened by straps of adhesive plaster; so that it may not find its way into the chest. Something must be put into the end of the bougie, to prevent the fluid from escaping too suddenly. The plug may be taken out every day, and a little fluid allowed to escape. When the lungs were sound, this treatment has been successful. I have not seen many cases of this description; but Dr. Davis had several; and he could count up a considerable number, where life has been saved entirely by this method.

Besides the surgical treatment of such a case,—letting out the fluid,—it is necessary to support the strength, and to lessen the irritation by means of opiates;—to use the same constitutional means that we should employ in the case of a large abscess.

\* See Dr. Forbes's Translation; Part 1; Book 3; Chapter 1; Section 6. (Third Edition; Page 459.)

<sup>a</sup> Physician to the London Hospital.

## SECTION III.—HYDROTHORAX.

*Pathology.*—It sometimes happens that an effusion of fluid takes place into the pleura, without much inflammation. A quantity of serum is effused there; sometimes quite clear; sometimes more or less turbid, and of various characters; but it is not pus, nor is it the result of inflammation. 'This is commonly called "hydrothorax."<sup>a</sup> When speaking of dropsical effusion, I mentioned<sup>b</sup> that effusions in a serous membrane were sometimes puriform, sometimes purulent, sometimes bloody, and so on; and I mentioned that sometimes they arise from *violent* inflammation, sometimes from *moderate* inflammation, and sometimes, apparently, without any inflammation at all.<sup>c</sup> Now the pleura is in the same predicament as all other serous membranes. It is frequently in the state I have now mentioned from inflammation; but sometimes it contains a quantity of thin fluid, where there was scarcely any inflammation at all,—where there was no necessity to employ antiphlogistic means; and sometimes it contains a large quantity of serum, without our being aware (not only during life, but likewise after death) that inflammation has occurred;—in fact, without the least sign of inflammation. Effusion may take place in the pleura, as in other parts, without any signs;—just as a person may sweat, and pour forth fluid, without any inflammation whatever.

*Idiopathic Hydrothorax very Rare.*—A genuine idiopathic case of hydrothorax (water in the pleura) is a very rare thing. Some people who never examine the chest during life, but who open bodies after death, speak of hydrothorax as the most common thing in the world; but when it does not arise from inflammation, hydrothorax is a rare disease. When there is any other disease in the chest, it is common for effusion to take place; but for it to take place, except as a consequence of inflammation, or some organic disease in the chest, is very rare. I do not recollect half a dozen such instances.

*Auscultatory Signs.*—When hydrothorax occurs, whether it is the result of a very slight kind of inflammation, or is produced by bronchitis, or peripneumonia, or disease of the heart, or any other disease, the symptoms discoverable by the ear are just the same as those that occur when the fluid is puriform or purulent, and the result of decided inflammation. There is, of course, a dull sound on percussion, from the presence of fluid; and there is no respiratory murmur at the lower part, although we may still have it at the *upper* part (unless the chest be completely filled), below the clavicles; and also on each side of the spine, where the fluid does not compress the roots of the lungs.

*General Symptoms.*—The general symptoms are difficulty of breathing, deficiency of urine, swelling of the legs, cough, and a sudden starting from sleep; but all these things, when they do occur with a certain degree of effusion into the chest, are more frequently the result of other diseases in the chest than of hydrothorax. In almost every case of hydrothorax, we find, on examination, other disease sufficient to explain the symptoms. In most cases there is disease of the heart, or chronic disease of the lungs; and in those affections we have exactly the same symptoms; although there may not be the same quantity of fluid effused into the pleura. I have frequently opened patients, who have been supposed to have died of hydrothorax; whereas death arose from disease of the heart.<sup>a</sup> Cases are frequently set down as hydrothorax;—where the legs are swelled; where the breathing is so difficult that the patient is unable to lie down; where he has orthopnoea and deficiency of urine; and where there is a collection of symptoms which are pronounced to be hydrothorax; whereas, on listening to the chest, we hear respiration all over it; and we hear the usual sound on percussion; but on listening to the heart, we hear disease of that organ; or on listening over the chest, we find sonorous and sibilous rattles;—showing that there are other diseases present. The fluid that occurs in the chest, when it is not puriform, is usually the result of some other disease in the

<sup>a</sup> From *ὕδωρ*, water; and *θώραξ*, the chest.

<sup>b</sup> See Pages 149, 152, 172, and 173.

<sup>c</sup> See Page 153.

chest. In cases of effusion into the chest, we have, in all circumstances, the same auscultatory phenomena;—not only the want of a respiratory murmur;—not only the want of a hollow sound on percussion; but, if the fluid be not considerable, there is also ægophonism. No matter what the disease is, the phenomena are the same.

*Treatment.*—If we can ascertain that there is really hydrothorax, to an amount sufficient to explain the symptoms;—that there is a dull sound all over the chest on percussion; that the respiratory murmur is not heard anywhere except just below the clavicle, and at the root of the lungs; and if we see the general signs of dropsy, and the absence of disease of the heart;—we then may presume that the extreme difficulty of breathing, the swelling of the legs, and the scantiness of the urine, arise from a collection of fluid in the chest;—especially if ægophonism be present; and if we observe that the dulness of sound, and the want of respiratory murmur increase,—reaching higher and higher. In such a case we ought to let out the fluid. Exactly as in other cases, where the presence of a collection is doubtful, we may use the needle which I spoke of,<sup>a</sup> to ascertain whether fluid exists or not. It would be well to do it in every case; because it gives no pain to the patient, and is perfectly safe.

*Diuretics.*—But before these measures are taken, it would be right to give the common remedies for dropsy, where there is no inflammation;—to give diuretics. Digitalis answers an excellent purpose, and also squills; more especially if united with a small quantity of mercury, which appears to increase the diuretic effect. A great deal of good may be effected by these remedies, in all cases of chronic difficulty of breathing,—whether there is effusion of serum or not; because there is continually a great collection in the air-cells, and perhaps also in the cellular membrane of the lung, which impedes respiration. When there is not hydrothorax, properly speaking, we continually find that diuretics are very useful, by causing an absorption of the fluid which is oppressing the cellular membrane of the lungs, or filling the air-cells themselves. I mentioned, when speaking of dropsy, that diuretics answer more purposes than one.<sup>b</sup>

#### SECTION IV.—PNEUMATO-THORAX.

*Etymology.*—The pleura is sometimes distended by air. This disease is called, by Laennec, "*pneumo-thorax*;"<sup>c</sup> but very improperly so. It should be "*pneumato-thorax*." Such compound words are always made from the dative singular;—the final letter being changed into *o*, if it be any other vowel. We thus have "*utero-gestation*," "*cerebro-spinal*," "*hæmato-cele*." The genitive and dative of *αἷμα*, are *αἵματος*, *αἵματι*. The genitive and dative of *πνεῦμα*, are *πνευμάτος*, *πνευμάτι*; and the compound word should be "*pneumato-thorax*." In truth, we already have "*pneumatophalos*," to signify a flatulent umbilical hernia; and, what is still closer, we have "*pneumato-cele*." Laennec, therefore, is wrong in the name which he has given to the disease; which consists of air being present in the pleura. This, however, is unimportant; and one is not disposed to dwell upon words; only when a new term is invented, it is right to make it legitimate, according to other words. With words that have been long established, we must be contented, and not be over nice.

*Signs.*—When air exists in the pleura, it of course gives rise to the same effects of distension, that the existence of pus or serum does. The intercostal muscles swell out a little; and the diaphragm and liver, in the case of the right side, are pushed down. We may predict what will be the signs to the ear. The air that is inclosed is not the air of respiration; but exists externally to the lungs; and therefore it does not give any respiratory murmur; but there is this great difference;—

<sup>a</sup> See Page 815.

<sup>b</sup> See Pages 172 and 173.

<sup>c</sup> See Dr. Forbes's Translation of his Treatise; Part I; Book 3; Chapter 4. (Third Edition; Page 499.)

that if we strike the chest, notwithstanding there is no more respiratory murmur than in the abdomen, yet we have a fine clear hollow sound. Here is an instance of the importance of not trusting either to percussion or to the stethoscope separately;—being a case in which the combined use of percussion and auscultation is necessary. If we merely *strike* the chest, in these instances, we find nothing wrong; for it gives a fine hollow sound;—perhaps a clearer sound than in health. Again, if we only *listen* to the chest, without striking, we shall say—“Here is a lung solidified;” or—“Here is a pleura filled with liquid,—with pus, or with serum.” But, by using both, the nature of the case is clearly seen. We ascertain, by the fine hollow sound, that air is there; but, by the want of respiratory murmur, we perceive that the air has nothing to do with the lungs.

When speaking of liquid in the pleura, I mentioned that, however large the collection might be, we should still hear respiration about three fingers’ breadth from each side of the spine;—that the roots of the lungs were never so compressed, but that we might hear respiration there; although, in extreme inflammation of the lung, the lung becomes so solid, that no respiration can be heard. Now it is exactly the same when the pleura becomes distended with air. When the lung is compressed by air in the pleura, still the compression is never so great, that respiration cannot be heard at the roots of the lungs;—at least, it must be an extremely rare occurrence. The lung still resists sufficiently to maintain its function at the roots; and, consequently, at the sides of the spine we may hear the respiratory murmur.

*Diagnosis from Emphysema.*—There is one case in which the auscultatory phenomena resemble those which are noticed in pneumato-thorax; and that is one that I have already mentioned, under the head of “chronic bronchitis.”<sup>a</sup> It is when the air-cells are greatly distended, and perhaps broken one into another. When the disease improperly called “emphysema of the lungs”<sup>c</sup> takes place, there is a great cavity in the lungs, filled with air. I say “improperly” so called; because “emphysema” is the existence of air in the cellular membrance; and in this case it is contained in the air-cells of the lungs. I mentioned,<sup>b</sup> that there is a very clear sound on percussion; but that, on listening to the respiratory murmur, we scarcely hear any thing. The cases are very similar in their nature; that is, cases where air exists in the pleura; and cases where some of the air-cells are very much enlarged, and partly broken down; so that a body of air exists in the substance of the lungs, and does not pass and repass as it ought to do in respiration. There is, however, a mode of distinguishing between the two cases; and it is this. When air exists in the pleura, we hear no respiratory murmur at all at the front of the chest;—it is stagnant: but in the case of dilatation of the air-cells, the air, although nearly stagnant, is never quite so;—it is partially expired and inspired; and therefore we do hear a faint respiratory murmur. Another mode of making the diagnosis is this. When the case is one of dilatation of the air-cells, it is consequent upon a long-continued catarrh, or bronchitic affection. It only takes place when the disease has existed a long time; and we hear the mucous, sonorous, and sibilous rattles of bronchitis; so, that, altogether, we may very clearly make out the nature of the case; whereas when air exists in the pleura, it is, for the most part, a very sudden affection. There are no signs of bronchitis; and it is not only sudden, but generally very violent; and usually confines the patient to his bed.

## SECTION V.—HYDRO-PNEUMATO-THORAX.

*Its Nature.*—A compound case sometimes happens;—one made up of the two affections of which I have last spoken;—of “hydro-thorax,”<sup>d</sup> or empyema, from the fluid existing in the pleura; and of “pneumato-thorax,”<sup>e</sup> in which air exists

<sup>a</sup> See Page 811.

<sup>b</sup> See Page 751.

<sup>c</sup> See Page 749.

<sup>d</sup> See Page 816.

<sup>e</sup> See Page 817.

in the pleura. We sometimes see patients with both air and fluid in the cavity of the pleura. This affection is termed "hydro-pneumato-thorax." It is a long word, but very expressive. It shows, at once, the nature of the case;—"hydro-thorax," the name for *liquid* in the chest; and "pneumato-thorax," the name for *air* in the chest. There is nothing puzzling in the name.

*Symptoms.*—On reflection, we may (as in many other cases of affection of the chest) say beforehand what will be the symptoms of this disease perceptible by the ear. The *air*, of course, must be at the *upper* part of the chest,—unless there be adhesions there; and the *liquid* will be at the *lower*; and therefore, on percussion at the *superior* part, we have a *clearer* sound than natural; but on striking at the *inferior* part, there is a *dead* sound. The contrast is very great indeed. On listening with the stethoscope, during respiration, to all parts of the side of the chest, we hear no respiratory murmur. The air above, and the liquid below, impede respiration; and therefore there is no respiratory murmur, either in the one situation or the other. But there is this difference between simple *hydro-thorax*, and *pneumato-thorax*;—in the former case there is a *dead* sound, from the presence of the *liquid*; while in the latter there is a *clearer* sound than natural, from the presence of the *air*; and in a compound case there is a *dead* sound *below*, and a *clear* sound *above*. Again: if we alter the position of the patient, we alter the situation of these phenomena. If the patient under examination be sitting or standing upright, the symptoms will be what I have stated. But suppose we make him lie down. The *hollow* sound, instead of being at the *superior* part of the chest, will then be altogether at the *anterior*; and the *dead* sound, on percussion, will be quite by the *side*;—simply by altering the relative position of the air and the fluid.

*Fluctuation.*—There is, however, another circumstance which takes place only in this disease. If we suddenly shake the patient,—take him by the shoulder and jolt him, we frequently hear fluctuation. We cannot hear fluctuation in empyema alone; neither can we hear it in hydrothorax; not is it audible where only air exists in the chest. It is only perceptible in hydro-pneumato-thorax. We may hear the fluctuation with the naked ear applied to the chest; or by means of the stethoscope. It is well, in all cases of this sort, to put the ear on the patient's chest, and let some one move him rather suddenly; and then we hear fluctuation within, and the patient will be aware of it himself. Sometimes the patient has discovered this, before the medical attendant has thought of the nature of the case. In a volume of the "Dublin Transactions," there is reported a very remarkable case, which occurred before Laennec's time. The patient did not say, like the woman in Scripture, that he had spent all his substance on physicians; but he had been to all the doctors within his reach; and, moreover, he had been sent to the Continent; but it was all in vain. Nobody knew the nature of his malady; and he discovered it at last himself. He found that when he was sitting up, or jolted himself in any way, he heard fluctuation within his chest. He pointed the attention of his medical attendant to it; and then the latter, for the first time, listened to his chest. This phenomenon is mentioned by Hippocrates, or in some of the works ascribed to him; but, unfortunately, it is there said that it takes place only when pus exists in the chest. This is incorrect. It takes place only when there is both liquid and air in the chest; the reason of which is very evident. Those who attended to what Hippocrates, or the writer of this passage said, endeavoured to verify it by dissections; but they found that the observation was inaccurate, and therefore it dropped to the ground; and medical men neglected to apply the ear to the chest, (although Hippocrates had done so,) and stigmatized the plan as mere nonsense. Unfortunately the observation was not sufficiently minute. The sound was ascribed solely to the existence of pus; and so the mistake was made.

*Metallic Tinkling.*—Another symptom which exists when there are these compound contents (air and liquid) in the pleura, is "metallic tinkling." This sound may be heard, most frequently, by putting our ear to the patient's chest, and then

suddenly raising him, or causing him to be raised upright. It is supposed that a portion of the pus then drops from the upper part of the chest, down into the lower part; and thus produces the sound. At any rate, the way I have stated is one of the best modes of hearing it. We may hear it by this means, when we cannot hear it in any other mode; but in one particular case of air existing in the pleura, it may be heard when the patient is speaking, coughing, or even breathing; and that case is where the air has got into the pleura through the lungs. It appears that air may sometimes be secreted in the pleura; sometimes it is the result of a decomposition of puriform fluid; and sometimes it enters the pleura through a rupture of the surface of the lung. If a communication be established between the lung and the pleura,—whether by the ulceration of a tubercle, by rupture, by gangrene of the surface of the lung, or by a wound,—then this clear silvery sound is heard when the patient is speaking;—perhaps when he is coughing, or when he is breathing. An aperture of this description, most frequently takes place from an abscess of the lung,—from a tubercle bursting; so that both air and pus are effused into the cavity together; and in this case there is always a clear “metallic tinkling.”

*Case.*—I may here mention a patient, in whom there was a most beautiful metallic sound. On striking the chest when I first saw him, I found a perfectly dead sound all over the lower part of the chest; and, being told that it was a case of consumption, of course I did not know the reason of it. But, on listening above, I found no respiratory murmur: and the nature of the case, in my estimation, was then clear. When he spoke, there was a fine, clear, ringing sound all over the chest; and when he coughed, it was exactly the same. After a time, it entirely disappeared; and then, I presume, a small cavity which had existed in the lung,—forming a communication between the lung and the pleura,—had healed. In about a fortnight, there was no ringing sound to be heard; and the patient, after going into the country, was apparently a great deal better. After a time, when I saw him again, there was still no respiration to be heard over nearly the whole of the chest; and there was a dead sound on percussion;—not merely at the *inferior*, but also at the *superior* part of the thorax. There was no more metallic tinkling; and it was clear that what had been filled with *air*, was now filled with a *liquid*. An operation was performed; and a quantity of liquid was let out, day after day, till it amounted to many quarts,—*gallons*, I believe. I forget how much was evacuated; but it was an immense quantity. Unfortunately, however, there was too much disease of another kind for the operation to cure him.

*Amphoric Buzzing.*—When air exists in the pleura, in consequence of such an opening as I have now described, before the silvery sound is heard, we may occasionally hear a particular sound, from air going in and out of the opening; and it is so much like the sound which we make when blowing air into a bottle, that it has been called “amphoric buzzing.” I do not recollect ever having heard it.

*Diagnosis from Abscess of the Lungs.*—I mentioned,<sup>a</sup> that when the air-cells are dilated, and a cavity filled with air exists in the lungs, the symptoms in some measure resemble those arising from air existing in the pleura; because the one is a great cavity, and so is the other. Now if it so happen that a great cavity exists in the *lung*, filled half by pus, and half by air, the circumstance is very much the same, as when the occurrence takes place in the *pleura*. Just as a cavity in a large dilated air-cell, resembles a cavity in the pleura, and gives rise to nearly the same symptoms, so a large *abscess* in the lung, filled half with air and half with fluid, resembles the pleura when in the same condition; and therefore we have the same phenomena;—that is to say, “metallic tinkling.” If the symptoms take place from a large abscess (containing both air and fluid) existing in the lungs, on raising the patient suddenly, a drop will descend from the upper to the lower part, and cause a silvery sound. But if the case be not very clear, it can be made out from this circumstance;—that, when a cavity exists in the *lungs*, we shall have

<sup>a</sup> See Page 818.

pectoriloquy, or the air going through the tube, as if the person's mouth were at the other end of the stethoscope; whereas, in cases where the *pleura* is affected, as there is no great communication between that and the bronchial tubes, we do not have this phenomenon. Where an abscess in the lung, containing partly air and partly fluid, is large, it will give a sense of fluctuation, upon suddenly shaking the patient.

*Causes of Pneumato-Thorax.*—With respect to the *cause* of pneumato-thorax, far more frequently than otherwise, it takes place suddenly; and I believe that, most frequently, it happens to phthisical patients; in whom, unfortunately, a tubercle has existed close to the surface of the lung; and nature has not formed an adhesion of the surface of the lung to the costal pleura; so that ulceration has gone on to the pulmonary pleura, which has become thin, and at last has ulcerated through. It has frequently happened, that when a patient labouring under phthisis has made a violent effort, rupture has taken place. The general symptoms are extreme dyspnœa; and a person who does not use his ear, might perhaps be led to suppose that it was merely an attack of inflammation;—especially if the patient had been running out of doors in the evening. One might then suppose, that the patient had caught a violent cold; and he might be bled and blistered all to no purpose;—the nature of the case simply being, that air had escaped into the pleura. The importance of listening to the chest, in such a case, is evident; for we may make out the nature of the case, clearly enough, by striking the chest. There is a perfectly clear sound; and yet, on listening to the respiration, we hear no respiratory murmur.

*Treatment by Operation.*—In such circumstances, an operation should be performed. The parts should be punctured, and the air let out. An interesting case of this description occurred to Dr. James Johnson.<sup>a</sup> It happened to a medical practitioner, who ran to a case of midwifery; and was seized with difficulty of breathing, and the symptoms I have just mentioned. Several practitioners were called in; one of whom said that he had had a similar case the preceding winter, and that the patient was cured with hyoseyamus; but nobody had the least idea of the true nature of the affection, except Dr. James Johnson; and he was so satisfied respecting it, that Mr. Guthrie, (I think,) at his request, made an opening into the chest; and out came a rush of air, and the patient felt immediate relief. This was a great object effected;—ease after pain. The patient died afterwards, because he was phthisical; but had there been no other disease than this accidental escape of air, no doubt he would have done well. If the collection of air occur on the left side of the chest, it will push the heart to the right side;—just in the same way as a collection of *liquid*. Of course the operation would not be required, merely because we hear air in the chest. It need only be performed where there is such difficulty of breathing, as to make it necessary to do something for the relief of the patient. So in a compound case,—one of hydro-pneumato-thorax, where there is both air and water in the chest,—no operation would be required, unless there were extreme dyspnœa. It is best to make the opening large enough to let out the liquid; so that, after the air has escaped, the liquid may also be evacuated.

*General Treatment.*—The general treatment would be that of phthisis, or a large abscess;—supporting the strength, &c. These are rare cases comparatively; but it is very necessary to know them. Every now and then, in practice, we meet with such a case; and by knowing the nature of it, we may lessen the patient's sufferings, and sometimes even cure him. When air exists in the pleura from gangrene of the lung at that spot, and the separation of the eschar,—a circumstance which will occur when the gangrene is quite partial,—the operation, in such a case, might be followed by complete success. If the air were disengaged merely from a quantity of fetid pus underneath, it is possible that the operation might be the means of saving the patient's life,—by putting an end to the dysp-

<sup>a</sup> "See the Medico-Chirurgical Review;" Volume 10.

nœa, which would perhaps have killed him; and then the other disease may be made to subside. Phthisis is rarely cured; but these other affections sometimes are. It may happen, therefore,—unless the patient have phthisis,—that the disease may be permanently cured.

[The measures calculated to relieve the symptoms of pneumothorax with perforation, vary considerably;—according to the period of the lesion, and the condition of the system. In the first instance, the perforation and access of air and matter to the pleural sac, are often attended by considerable prostration of the system, with rapid feeble pulse and faintness; together with the pain and cough, which are then the result of irritation, rather than inflammation. Considerable doses of opium or morphia are necessary to allay this irritation; they may be advantageously combined with calomel and antimonials; and sinapisms or warm fomentations may be applied to the affected side. More active antiphlogistic measures cannot be used until the reaction takes place; which generally begins in a few hours;—bringing with it heat of the skin, strength and hardness of the pulse, the great soreness as well as pain of the whole affected side; then blood-letting, chiefly local, must be used, with aperients and salines;—according to the strength of the patients, and the degree of fever present. These may be followed by blistering, or tartar-emetic counter-irritation, in proportion to the continuance of the inflammatory symptoms. But it is not to be forgotten, that perforation of the pleura and its consequences are almost always added to a previously existing disease,—tuberculous phthisis; and the degree of advancement that this may have reached, must much limit the propriety and efficacy of the measures for this accidental inflammation that has been excited. The same considerations are to be kept in view when, in consequence of the smallness of the perforation, or its valvular condition, air accumulates in the chest, and becomes the cause of oppressive dyspnœa. The immediate indication in this case is, doubtless, to give exit to the air by puncturing the chest; and this has been done in several instances, with great temporary relief. But before this operation is prescribed, it should be considered whether, as the relief from it will be but temporary, the condition of the patient be such as to make this likely to outweigh the pain and risks of the operation. These certainly are not great; but, when added to the dubious view in which the friends of the patient may regard an operation which proves but imperfectly successful, they are sufficient to deter us in many cases from recommending it. The case is different when the accident occurs before the consumptive disease has advanced far;—when there is much flesh and strength, and when the physical signs have shown that there is a large proportion of sound lung. The operation may be repeated if the air accumulate again. As it is impossible to avoid the continued introduction of air into the chest, the mode of performing the operation is a matter of much less consequence than in empyema. It is more desirable to puncture below the level of the liquid;—to allow this, as well as the air, to escape.<sup>a</sup>]

## SECTION VI.—ORGANIC AFFECTIONS OF THE PLEURA.

*Tubercular Disease of the Pleura.*—There are certain other diseases of the pleura, of an *organic* nature; upon which I will not dwell long. Occasionally the pleura is attacked by the same disease which, when it exists in the lungs, forms phthisis. The pleura is sometimes, though not very frequently, in a state of tubercular deposit. Sometimes, in phthisis, we find one pleura, or both, studded with tubercles of various sizes;—generally small, but sometimes of a large size.

*Symptoms.*—The deposition of tubercles in the pleura, may be attended with scarcely any symptoms whatever; because phthisis may exist at the same time; and the symptoms of the *greater* disease, may swallow up those of the *small* one. But sometimes, if the disease exist alone, and is of any considerable amount, there

<sup>a</sup> "Library of Medicine," Volume 3; Pages 133 and 134.

will be all the signs of a pleuritic effusion into the chest;—all those symptoms which I just now mentioned; and it may not be easy to make a diagnosis, in a case of this description. On making a post-mortem examination, we are often surprised at finding tubercles in the pleura. But if the disease be considerable in any one spot, we shall have marks of pleuritis. Inflammation will take place around the tubercle; and suppuration will occur. But it is not easy to distinguish inflammation from such a source as that, from inflammation of a simple nature. When the tubercles suppurate, pus may be discharged into the pleura; or, without suppuration, there may be an effusion into that cavity, from excessive secretion; and the secretion may be either serous or purulent. In fact, we may have pleuritis, and all the *consequences* of pleuritis; so that air may pass in, and all those other changes will take place which I mentioned as occurring without tubercles;<sup>a</sup> and the patient will become hectic.

*Treatment.*—The treatment of the case will depend entirely upon the presence of air, the presence of liquid, the presence of inflammation, and so on. It is only necessary to know, that all the changes which I have mentioned,<sup>a</sup> are sometimes connected with tubercles in the pleura itself; and that sometimes very minute tubercles will exist there, and give rise to scarcely any symptoms at all. Tubercles are frequently observed there, when they are seen in various other parts of the body. More frequently than not, perhaps, when pleuritis is chronic,—when the patient has a fixed pain of an inflammatory nature in the pleura, and wastes away, it is a serofulous affection; and is attended by this tubercular deposition. The tubercles, most probably, are situated in the cellular texture, immediately under the serous membrane.

*Ossification of the Pleura.*—I have seen the pleura ossified to a great extent. Here, again, it is not the *pleura* (properly speaking), that is ossified,—at least *originally*; but it is the cellular membrane under it. The cellular membrane is frequently converted into bone, in various parts of the body; or bony deposit takes place in the cellular membrane. Perhaps the latter is a more accurate mode of speaking. But the pleura above the bone will sometimes disappear,—waste away; so that, on looking into the cavity of the pleura, we perceive the bare bone. I recollect once meeting with this occurrence, to a great extent, in an old man who died of ascites and liver-disease; and who was not aware that he had disease in the pleura;—at least, he never attracted our attention to it. I recollect remarking how well he could lie down, notwithstanding the fluid in his abdomen. I found the pleura covering several ribs, in a state of ossification.

*Scirrhus, &c.*—Other affections may occur in this situation. We may have scirrhus, and melanoid disease; but these are comparatively rare affections.<sup>b</sup>

<sup>a</sup> See Pages 816, 817, and 818.

<sup>b</sup> We cannot take leave of Diseases of the Lungs, without directing the attention of our readers to “A Treatise on the Diagnosis and Treatment of Diseases of the Chest. By William Stokes, M. D.” In this, the most able work we possess on the subject, one of the first stethoscopists of the day, has given us the result of great talents and ample opportunities, brought to bear, for a long series of years, on this, his favourite department of medical investigation.

## BOOK IV.

### DISEASES OF THE HEART.

---

#### CHAPTER I.

##### PERICARDITIS.

PERICARDITIS, the first disease which I purpose to consider, would never be selected to show the advantages of auricular examination; which, in the acute form at least, is (for the most part) of only negative utility. But the consideration of it will prove the injustice of those who assert, that auscultators both regard auscultation as a universal light, and neglect the general investigation of symptoms.

*Frequent in Occurrence.*—The acute inflammation which occurs in the region of the heart, is usually situated in the pericardium; and pericarditis is a very common disease.

*Anatomical Characters.*—The anatomical characters are little different from those of inflammation of other serous membranes.<sup>a</sup> There is either a partial redness,—patches, sometimes as if the membrane were injected, at others as if dyed red,—or groups of red points. The redness is seldom deep; and, in the most violent cases, is often very faint. The membrane was never, in a single instance, observed by Laennec to be thickened;<sup>b</sup> though Dr. Baillie declares this to be frequently the case;<sup>c</sup> but upon it lies a quantity of fibrin, thicker and more consistent than in pleurisy; and differing from the fibrin of pleurisy, also, in being generally irregular on its surface;—sometimes with minute pores, sometimes with depressions so large as to give it the appearance of the second stomach of the calf, sometimes knobbed like butter spread upon two slabs (to use Laennec's comparison<sup>b</sup>), first approximated and then suddenly separated from each other. Dr. Baillie says that the fibrin never adheres firmly;<sup>c</sup> Laennec that it adheres more firmly than in pleurisy.<sup>d</sup> Although the redness is partial, this exudation is most frequently general, and often very abundant when the redness is slight. It is of the ordinary pale colour.

The serum effused is in far less proportion to the fibrin than in pleurisy;—seldom amounting to a pint, though it has amounted to four; and sometimes scarcely any is found. It is of the common whitish lemon-colour; rarely limpid, sometimes very turbid, containing larger or smaller flocculi of lymph, or absolutely cur-

<sup>a</sup> See Page 108.

<sup>c</sup> "Morbid Anatomy;" Chapter 1; Section 1.

<sup>d</sup> See his Treatise on Diseases of the Chest, translated by Dr. Forbes; Part 2; Book 2; Chapter 22. (Third Edition; Page 672.)

dled;—as if only one kind of effusion had taken place. Sometimes it is bloody, sometimes puriform: Dr. Baillic once saw a quart of pus in a pericardium violently inflamed, but free from ulceration.<sup>a</sup>

In the chronic disease, the redness is more intense and more diffuse, and the inflammation is almost always general. If any fibrin exist,—and it seldom does,—it is thinner and softer. There is always the turbid serous effusion.

As time elapses after the acute attack, the liquid effused is absorbed, the fibrin grows to the cardiac and parietal portions of the pericardium, and adhesions (more or less partial or general) of cellular or serous membrane are produced,—usually thinner and stronger, like those of other serous sacs, the older their date. The adhesions are sometimes very thick and fibrous,—as it were fleshy; and sometimes cartilaginous or bony. I have frequently seen the whole cardiac and parietal pericardium coherent, and even the proper auricles concreted to the ventricles; so that no pericardial cavity existed;—the serum being entirely absorbed, and the fibrin nearly so. Such cases have occasionally been mistaken for instances of the absence of the pericardium.

Both when the pericardium is very coherent, and when it is only thickened, the morbid action may be more intense in particular spots; for we often find, at different parts, knobs of cartilage, some of which dip deeply into the substance of the heart. Sometimes the fibrin effused becomes cellular; and, contracting no adhesions, lies pale (like lace) upon the surface of the heart: sometimes merely an opaque white patch, which can be peeled off, remains; and sometimes, instead of smooth patches, we have opaque white granulations. If the inflammation has been severe, lymph is often found (in more or less quantity) on even the external surface of the pericardium;—uniting it by bands to the pleura. The reason is not obvious, why the fibrin within the pericardium sometimes adheres, and sometimes contracts no adhesions. The degree of serous effusion and consequent proportionate separation of parts, affords no explanation; because, first, we often see one portion of lymph adherent, while another by its side is not; and, secondly, there is often a total absence of adhesion, without sufficient serous effusion to account for it.

The substance of the heart after pericarditis may be unchanged, or redder or paler than usual; yellowish or brown, hardened or softened. After the chronic disease, it has been found hypertrophied. It is usually when the organ is softened, that we observe the effused serum to be bloody. In “softening of the heart,” I have almost always found bloody serum in the pericardium. Not only the substance of the heart, but its lining membrane,—especially at the valves,—is also frequently affected; sometimes in the acute form,<sup>b</sup> but generally in the chronic, if very long continued.

We shall find, presently, that the majority of cases of diseased heart, both as to its substance and its valves, arise from, or (at least) are coetaneous with, or spring up during, inflammation of the pericardium.

*Causes.*—Pericarditis is occasioned by all the causes of the inflammation of serous membranes in general. But the most frequent is either exposure to cold,—especially after a warm temperature, and if rheumatism is also induced; or sympathy with the fibrous membranes of joints attacked by rheumatism. It will occur simultaneously with the rheumatism; or not till the rheumatism has existed for a longer or shorter period, has even gradually declined, or altogether ceased for some time; and, though the metastasis is comparatively rare, when the rheumatism suddenly disappears.

*Its Connection with Rheumatism.*—Pericarditis is usually not very violent, but is disposed to assume the chronic form;—frequently stealing on, as a chronic dis-

<sup>a</sup> “Morbid Anatomy,” Chapter I; Section 1.

<sup>b</sup> In the “Medico-Chirurgical Transactions” (Volume 7, Page 323), Mr. Stanley describes a case of pericarditis, that occurred with pain of an extremity, evidently rheumatic. The pericardium contained several ounces of turbid fluid, with flakes of lymph; and was covered, in various situations, with a reticulated layer of lymph. The substance of the heart was almost black with congested blood, was very soft, and was studded with little collections of dark pus.

ease, from the abuse of fermented liquors. In this case, the valves and (finally) the substance of the heart, as I have mentioned,<sup>a</sup> become diseased. From these circumstances, the connection between rheumatism and affection of the heart was first noticed in the stage of organic disease; and rheumatism was said to produce, not inflammation, but disease of the heart. Occasionally the pericardium may not be affected, and occasionally but in a secondary manner: but I am certain, that nearly all the cases of affections of the heart, after rheumatism, are originally pericarditis; and that, when the inner membrane is thus affected from the first, so also is the pericardium. Among the cases of organic disease of the heart connected with rheumatism, published by Dr. Wells, in the year 1812,<sup>b</sup> those which proved fatal displayed a complete abolition of the pericardial cavity, or strong or abundant partial adhesions; and those which did not prove fatal, were marked by decided symptoms of pericarditis. In nearly all<sup>c</sup> those mentioned by Sir David Dundas, in the First Volume of the "Medico-Chirurgical Transactions,"<sup>d</sup> the pericardium was adherent. Every dissection that I have made in cases that proved fatal during the early period of the disease, has proved the case to be violent pericarditis; the history of every chronic case that I have witnessed, could be clearly traced back to pericarditis; and every affection of the heart (however slight) that I have seen take place during rheumatism, has been marked pericarditis. The pleura, particularly of the left side, is occasionally inflamed at the same time; and the subsequent chronic organic disease of the heart, is of every possible variety.

*First observed by Dr. Pitcairn.*—Dr. Pitcairn, of St. Bartholomew's Hospital, was the first who noticed, about the year 1788, the connection of rheumatism with disease of the heart; and Dr. Baillie, in 1797, was the first who published on the subject.<sup>e</sup> They considered the disease to be a morbid growth of the heart. Sir David Dundas published upon the subject, many years afterwards,<sup>f</sup> without reference to the observations of these physicians; and even asserted his belief, that no account of the matter was to be found in any medical writer;<sup>g</sup> though, as Dr. Wells remarks,<sup>h</sup> "there is great difficulty in supposing him ignorant of what had been mentioned twelve years before, in so popular a work as Dr. Baillie's *Morbid Anatomy*." Sir David mentions the disease as dilatation of the heart, and chiefly of the left ventricle; with paleness and softness of its substance, and adherence of the pericardium.<sup>h</sup> But, from the imperfection of morbid anatomy in this country at the time he wrote,<sup>i</sup> his description is very loose. However, in one of Dr. Wells's cases,—which proved fatal early, and was opened by Sir Benjamin Brodie,—nothing but pericarditis was discoverable;<sup>k</sup> and Dr. Wells, no less distinguished for his sagacity than his independence, evidently regarded the rheumatic affection of the heart as inflammatory, by advising copious bleeding in the outset.<sup>l</sup>

The French do not appear aware of the connection of pericarditis with rheumatism, except as an ordinary instance of internal inflammation, upon the sudden retrocession of an external disease.

However, I think it is pretty certain that disease of the *heart* is not connected with rheumatism, except so far as the effect of *pericarditis* is connected with rheumatism. We every day see the latter occurrence; and whenever a case of disease

of the heart connected with rheumatism occurs in a young person, and the patient dies, we find marks of the preceding inflammation within the pericardium; and, on inquiring into the history of the case, we learn that there were originally symptoms of pericarditis. It is quite clear that the rheumatism is connected with the inflammation of the pericardium. I will not say it *produces* it; because all the symptoms result, perhaps, from the same state of the system: but the first thing *connected* with the rheumatism, is pericarditis; and then when that has existed any considerable time, the organic changes of the heart take place. We may easily, I think, satisfy ourselves of this, by reading all the cases that have been published of diseases of the heart, as consequent upon rheumatism. We find strong proofs of inflammation of the pericardium; and if the original history of the case be detailed, we shall see strong symptoms of pericarditis. In affections of the heart connected with rheumatism, we continually find that inflammation has taken place first, and that organic disease is consequent upon that. This is a very happy circumstance; because inflammation of the pericardium may be controlled, as easily as inflammation of any other part; whereas organic disease of the heart, for the most part, is an affection which we can only palliate. But it is not disease of the *heart* which is connected primarily with rheumatism, but *pericarditis*.<sup>a</sup> This is nothing more than might be supposed; because young persons, who are chiefly the subjects of this disease of the heart, are not subject to organic diseases, except scrofula. They are subject enough to *inflammation*; and we know that inflammation of any part whatever, will leave organic disease. The great source of organic disease, is inflammation; and it is quite capable of producing every organic affection whatever;—that is to say, of producing all *common*, and all *structural* diseases, and a predisposition to any *peculiar* disease. The debility produced by inflammation of another part, easily makes the patient the prey of a specific affection. But it is in *young* subjects that this affection occurs;—young subjects being particularly liable to *inflammation* of every description; and not to *organic* diseases of any kind, except scrofula.

*Duration*.—This disease would appear sometimes to remain very long mere pericarditis, or at least merely an inflammatory affection; for it is sometimes cured after a lapse of time, and sometimes continues for many years with no signs of organic disease;—proving troublesome only when cold is accidentally caught, and a fresh attack of rheumatism in the joints induced.

*Age at which it Occurs*.—Most instances of rheumatic pericarditis commence in persons from about the age of puberty to near thirty. We occasionally see it in the younger; rarely for the first time in the older. I once saw it in an infant. With neither of Dr. Baillie's remarks,—that pericarditis is not very common, and that it chiefly attacks persons who have been some time adults,<sup>b</sup> does my experience at all agree.

*Symptoms*.—Acute pericarditis is, of course, attended by more or less pyrexia. There is a pain in the region of the heart,—sometimes severe and lancinating; generally darting through to the left scapula, upwards to the left clavicle and shoulder, down the arm a certain way, and (what is remarkable) rarely extending quite so far as the elbow. I lately had a case, in which the pain extended down the forearm; but it did not quite reach the wrist. The pain is increased by pressing forcibly upon or between the ribs and cartilages over the heart; and by pressing, with the points of the fingers, upwards against the diaphragm, under the cartilages of the left false ribs; frequently even by pressing the epigastrium and left hypochondrium in the usual manner. The pain is often increased on inspiration, and by lying on the left side. I think patients in general lie most easily upon the back. The respiration is rapid; but less so than in affections of the lungs. There is sometimes a cough, which is dry. Nearly always palpitation, frequently violent, at least upon exertion. Sometimes, though more rarely, a disposition to syncope. The pulse varies exceedingly. It is necessarily quick; and often, but not always,

<sup>a</sup> See Page 825.

<sup>b</sup> "Morbidity Anatomy;" Chapter 1; Section 1; Paragraph 1.

small, in proportion to the heart's action; and only sometimes intermittent and irregular; neither is it always hard, or even very full. The countenance is described as anxious, and the features contracted: but this, I imagine, happens only when the pain is acute; and it is equally the case in pleuritis.

*Auscultatory Signs.*—On examination by the ear, the *whole* heart is found acting more forcibly, and with a clearer sound, than in health. But this is all. Auscultation, however, appears to be of negative use. We do not discover the loud murmur of the sonorous or sibilous rattle of bronchitis, the crepitous rattle or obscure respiratory murmur of pneumonia, or the ægophony of pleuritic effusion, unless these diseases are combined with the pericarditis. Neither have we the partially excessive or defective impulse or sound, or preternatural sounds, of organic diseases of the heart. In all uncombined cases, therefore, light is thrown on the disease. I remember having once found auscultation of great use, in the diagnosis of a disease which might have been considered clearly pericarditis. The patient was a poor Irishman; and the Irish are by no means happy in their attempts at a lucid history and description of their diseases. He complained of pain (increased on pressure) in the region of the heart, palpitation, and dyspnœa; and declared he had been ill but a few days. The case appeared to be pericarditis. The pulse was full, and the constitution good. There appeared every reason to bleed him freely, and to put in force the whole antiphlogistic plan. But, on listening to the heart's action, the left ventricle gave a violent dead noiseless blow against the chest; and the case was evidently one of hypertrophy of the left ventricle. I insisted to the man that he had long been ill; and it was ascertained, from his own mouth and from his wife, that he had suffered palpitation and dyspnœa for a great length of time; and that the error of his history arose from his having been compelled to leave off work only a few days before. He died in a fortnight; and great hypertrophy of the left ventricle was discovered.

M. Collier says, that the action of the heart is accompanied by a sound resembling that of new leather. Laennec does not mention it; but remarks the occasional occurrence of a sort of click, which some persons mistake for a “bruit de soufflet.”<sup>a</sup>

[At an early stage of the disease, inflammation of the pericardium often gives rise to considerable serous effusion. In consequence of this, the impulse of the heart diminishes, and the sounds become feebler and more distant. Percussion also yields a dull sound, over a larger space than natural, in the region of the heart. This dullness may commonly be detected at a pretty early stage; and although at first, perhaps, dependent upon mere turgescence of the heart, soon becomes more marked in consequence of the effusion, of which it marks the limits. Frequently, also, by careful examination, we may discover a circumscribed fulness or elevation of the chest in the same region, where at the same time the respiratory murmur is no longer heard. Of course, in those cases where lymph only is effused, or where the amount of serum is quite small, the above combination of physical signs is not met with, and the impulse of the heart may remain strong throughout, accompanied by a corresponding strength and hardness of the pulse. The compression of the heart, on the other hand, by a considerable quantity of fluid, sufficiently accounts for its feeble and irregular action in certain cases, as well as the corresponding characters of the pulse and general symptoms, the faintness, dyspnœa, &c.—T. S.]

*Diagnosis.*—The diagnosis of pericarditis is thought by many to be extremely difficult. Laennec declares that he has frequently suspected it where it was not found, and found it where he had not suspected it.<sup>b</sup> By close inquiry into the existence of all the marks just mentioned,<sup>c</sup> I have never found the diagnosis difficult. I would particularly lay stress upon the extension of the pain from the region

<sup>a</sup> The contraction of the ventricles yields a greater shock, and sometimes a more marked sound, than usual; and, at intervals, feebler and shorter pulsations are perceived; which correspond with the intermissions of the pulse.—“*Forbes's Translation of Laennec's Treatise on the Chest*,” Part 2; Book 2; Chapter 22. (Third Edition; Page 676.)

<sup>b</sup> See his *Treatise on Diseases of the Chest*, translated by Dr. Forbes; Part 2; Book 2; Chapter 22. (Third Edition; Page 675.)

<sup>c</sup> See Page 827.

of the heart to the scapula, shoulder, and a certain way down the arm;—symptoms which patients will not always mention, unless questioned respecting them: and its increase on strong pressure upon or between the ribs and cartilages over the heart, and upwards under the cartilages of the left false ribs. These two points I do not remember to have seen mentioned anywhere; and the others are not dwelt upon in some of the best books. In Andral's "*Clinique Medicale*," pain of the epigastrium on pressure is said to have occurred in some cases; but the point is not spoken of as if inquired into: in one case only is the extension of pain to the arm mentioned; and its extension even to the shoulder does not seem to have formed an object of inquiry.

I am certain that, by a scrutinizing examination, the existence of pericarditis will very rarely be mistaken: and from this conviction, and the frequency of its occurrence during acute rheumatism, I make it as invariable a rule to examine the cardiac region by the touch and hearing in every case of acute rheumatism, as the usual seats of hernia are examined by us all in cases of colic and intestinal inflammation. Were this rule universally observed, practitioners would not be occasionally surprised by the death of patients, in what had been considered merely acute rheumatism.

*Treatment.*—When the disease is acute, there is nothing peculiar in its treatment;—being the same as that for active inflammation in other parts of the body. Only it is to be remembered, that this inflammation is seldom violently active; and is generally disposed to become chronic. When acute inflammation is not very intense, the best way of attempting to remedy it, is by local bleeding; so in this case, I have observed free local bleeding to be more serviceable than general depletion. Mercury is of equal efficacy in acute pericarditis, as in other acute inflammations; over which, wherever they may be situated, a very extensive experience of many years has fully satisfied me,—conformably with the observations of so many able physicians,—that it possesses far more power than any other medicine. Bleeding and other ordinary measures cure cases of severe inflammation every day; and, in cases of little danger, may be relied upon. But they frequently fail in cases of intensity; and they know that if, in addition to suitable bleeding, mercurial ptyalism is quickly induced, active inflammation will very rarely destroy; and not only is fatality almost always prevented, but far less bleeding is required. This has been my practice, from the commencement of my professional life; and I have never met with a necessity for those frightful bleedings of quart after quart, recorded from time to time in our publications. I have given tartarized antimony (in quantities of a scruple and half a drachm every twenty-four hours), hydrocyanic acid, and other medicines recommended by the Italians; but found them all greatly inferior to mercury. Among the best, unquestionably, is colchicum; and its power over active gout and rheumatism of the extremities, is universally acknowledged to be very great. After the violence of acute pericarditis is subdued, it appears of use in restraining the morbid irritability which sometimes still continues in the heart; and several chronic cases, of which I had despaired, have gradually recovered under perseverance in its use for many months.

*Dropsy of the Pericardium.*—The quantity of fluid at a certain period of acute pericarditis, and in chronic pericarditis, is occasionally (but not often) so considerable, that "*hydrops pericardii*" exists. Inconvenience could scarcely arise from a less quantity than half a pint. Unless it is considerable, it is indicated with no more certainty by percussion and auscultation, than by the ordinary symptoms. But if the quantity be large, there is a dull sound to a great extent, on striking the cardiac region; the heart's action may be perceived very faintly, and perhaps in a diffused manner; so that the epigastrium pulsates or vibrates, and may appear fuller than in health: patients have experienced a sense of weight in the cardiac region, and even fluctuation has been detected. In cases of copious effusion of blood, pus, or serum, into the pericardium, these symptoms have suddenly appeared; and good examples of the occurrence of some of them may be found in Andral.

A fluid occasionally collects in the pericardium,—as in the pleura and perito-

neum, arachnoid, and "tunica vaginalis,"—by a slow process, not amounting to inflammation. The membrane is not red, but perhaps opaque; and even thickened, and of a satin-whiteness. This condition is, I believe,—where no redness of inflammation is visible,—the common cause of ascites, chronic hydrocephalus, hydrocele, and idiopathic hydrothorax; and though, like the state which gives birth (as I shall presently mention\*) to one kind of adhesions in serous membranes, it may be the result of a change allied to inflammation, it hardly merits the title of "inflammation;"—from the absence of inflammatory symptoms, the absence of redness in the membrane, the pellucidity of the fluid, and the inutility of anti-inflammatory measures.

*Adhesions.*—The adhesions within the pericardium left after pericarditis, are almost the only instances that occur in this membrane. I have never seen adhesions except with redness of the membrane, or the presence of turbid fluid, or after the existence of decided symptoms of pericarditis. In the pleura they are continually found, without the least previous symptoms of inflammation, and without redness or turbid effusion; and though, like chronic dropsy of the membranes, they may result from what cannot be proved to be a non-inflammatory state, they certainly (like it) are no proofs of any thing deserving the decided name of "inflammation."

In the case neither of the pleura nor pericardium, do they in general produce the slightest inconvenience. I have seen the whole pericardium so coherent, that its cavity was entirely abolished; and yet the symptoms which had been present were exactly commensurate with the organic disease of the heart which existed at the same time, and had certainly no relation to the adhesion. I cannot say I ever observed a symptom produced, except in one case; and there a single thick adhesion extended along the front of the heart. In the supine posture this must have been dragged down by the subjacent heart; and must have tended to drag the pericardium of the front of the chest with it, and to suspend the heart;—so that the parietal and cardiac pericardium, at their points of union with it, must have been put upon the stretch. The patient, accordingly, had been unable to lie on her back;—on account of a smarting pain produced, in this posture, at the front of the cardiac region. Bertin, in his excellent work upon diseases of the heart,<sup>b</sup> states that adhesions often produce no symptoms; but gives one case in illustration of the fact, that inconvenience sometimes is felt: yet in this case, adduced singularly enough, the substance of the heart, in addition to the adhesions, was found very soft;—a change quite sufficient to explain every symptom that occurred.

*Organic Affections of the Pericardium.*—The cellular side of the pericardium, like that of other serous membranes, is sometimes (though very rarely) the seat of hydatids and cysts, serofulons and other tubercles, and of ossification. The diagnosis must be impossible; and, indeed, no symptoms have in some cases been observable.

*Hæmorrhage into the Pericardium.*—The pericardium is the seat of sudden and fatal hæmorrhage without previous indisposition. Sometimes, like the arachnoid, it is perfectly dry. Sometimes it contains air, either alone or with a preternatural quantity of fluid; in the latter of which cases, fluctuation or undulation has occurred. Sometimes the pericardium is absent: at least five unquestionable cases of this singularity are on record.

\* See the previous Paragraph.

## CHAPTER II.

## DISEASE OF THE LINING MEMBRANE OF THE HEART.

## SECTION I.—GENERAL INFLAMMATION OF THE MEMBRANE.

I SHALL now proceed to describe affections of what may be called the membrane corresponding to the pericardium. The heart has a membrane within, as well as a membrane without;—a membrane which is continuous with the lining membrane of the aorta, and of the valves. This is subject to inflammation,—in the same way as the pericardium; but there are no signs by which we can ascertain its existence with certainty. We may occasionally *suspect* it; but, after all, I imagine it will be a mere guess.

*Anatomical Characters.*—After death, this lining membrane is occasionally found in a state of inflammation; but we are not to presume, in every instance in which we find redness of this part, that there is inflammation. If it so happen that the parts are all soft, they will become dyed by the blood; imbibing it after death, and becoming stained by it. Almost always, when the heart is softened in structure, this membrane is of a deep red colour;—simply as the effect of that imbibition, which I mentioned, when speaking of inflammation in general; and when I pointed out the necessity of being careful, in many instances, not to decide that there was *inflammation*, simply because there was *redness*.<sup>a</sup> But there is no doubt that this redness does sometimes result from inflammation. This is proved by fibrin being effused upon the coloured portion, and adhering to it closely. Another proof is, that we find the part which is so intensely red without a drop of blood in contact with it. Sometimes the membrane is red in particular valves, for example; and yet the whole cavity will be emptied of blood; so that it cannot be ascribed to the imbibition of blood from the part with which it was lying in contact. Occasionally this redness will arise from great dyspnoea. When, before death, there is long-continued difficulty of breathing, the mucous membrane of the stomach, intestines, and bronchia, becomes very red; and the right side of the heart becomes gorged with blood. In these cases we shall, in many instances, have redness of the inner membrane. But where a patient has died suddenly, and there has not been time for the gradual accumulation of the blood from the smaller vessels,—where after death no blood is lying in contact with the red part, the lining membrane is sometimes intensely red.

*Symptoms.*—In cases of this description there has sometimes been, before death, great rapidity of the pulse, rapid action of the heart, and more or less uneasiness and smarting in the region of the latter. If this occur within the aorta, for example, there is in general great rapidity of pulse, and a smarting sensation down the spine in the course of the aorta. In the case of the heart, the only reason for supposing its existence is that, in addition to the signs of pericarditis, (for pericarditis is generally united with it,) there is a very violent action of the heart; but I confess that, more frequently than not, I have found this appearance after death, without having had any reason to suspect it during life.

*Usually Chronic in its Nature.*—When the lining membrane is affected with inflammation, it is generally a mere *chronic* disease;—just like inflammation of the pericardium.<sup>b</sup> It undergoes the common changes produced by inflammation; it becomes thicker than it should be; and, at the same time, it becomes harder.

*The Valves most frequently Affected.*—The parts most frequently affected are

<sup>a</sup> See Page 80.<sup>b</sup> See Page 829.

the valves; which are nothing more than an elongation and doubling of this lining membrane. In the case of the tricuspid and mitral valves, a portion of tendinous structure likewise enters into their composition. The "*chordæ tendineæ*;" invested as they are by the lining membrane of the heart, run along into the valves, and are lost there in the lining membrane; so that the mitral and tricuspid valves, are made up of *fibrous* membrane and the *lining* membrane;—tendinous and serous membrane; whereas the semilunar valves of the aorta and pulmonary artery, are nothing more than the lining membrane itself, protruded and extended.

It is a general rule observed in pathology, that the lining membrane at the openings of the heart, is more subject to disease than other parts;—whether it be simple inflammation, or the effects of chronic inflammation in any other part. We know very well, that it is not the stomach at large which is generally diseased; but one of the openings;—the cardiac or the pyloric. We also know that, more frequently than otherwise, disease affects the intestines where the small intestines terminate in the large; or, again, where the large terminate in the rectum. The rectum is the great seat of scirrhus, stricture, and various other diseases of structure. In fever, ulcerations are more frequently found at the termination of the ileum than elsewhere; and there it is we continually see scirrhus and cancer of the intestines. Instances of disease of the cardia and pylorus, are infinitely more frequent than disease of the rest of the stomach. Exactly the same is observed in the case of the heart; so that we have infinitely more cases of disease of the *openings* of the heart, than any other part of the lining membrane. This is nothing more than an exemplification of a general rule.

*Left Side of the Heart most frequently Affected.*—There is another rule, however, which is peculiar to the heart; namely, that the left side is more subject to diseases of all kinds, and infinitely more to redness, than the right. That is a general rule, with respect both to the lining membrane within the heart, and with respect to the substance of the heart itself. Various hypotheses have been formed to explain this; but the most probable explanation is, that one side of the heart receives blood of an *arterial* character, whereas the other has blood of a *venous* character. It has been thought that one side of the heart does more work than the other; but in proportion it certainly does not. Every time the left ventricle contracts, the right does the same; and so with respect to the auricles; and if the left ventricle have to send its blood farther than the right, yet the structure is much thicker than that of the right; and thus it is fully qualified for the exercise of the duty which it has to perform. No difference that I can discover exists between them; except that one receives *arterial*, and the other *venous* blood. Whether that will explain the circumstance, I do not know; but we know, as a general rule, that arteries are more subject to active diseases of all kinds, than veins; and it is very probable that the greater stimulus of the arterial blood occasions other causes of disease, when applied, to act energetically; and also causes disease to take place with more readiness.

## SECTION II.—DISEASES OF THE VALVES OF THE HEART.

Inflammation of the pericardium, when chronic, is very frequently united with chronic inflammation of the membrane within the heart; and most frequently with chronic inflammation of those parts that form the valves. This is one way in which organic disease of the heart is produced; namely, by pericarditis. Pericarditis seldom exists long, without being followed by a similar state of the lining membrane within.

*Anatomical Characters.*—In the natural state, these valves are quite flexible; and, though not *transparent*, *translucent*. But when they have become chronically inflamed, instead of being light, they become yellow; and, instead of being translucent, they become opaque. They lose their flexibility, perhaps; and become more or less rigid. They play less easily; and at last become quite rigid. They

lose their fineness, and become thick; and not only thick, but dense. If these changes be not very severe, they give rise to no symptoms at all. If they do not prevent the passage of blood, by narrowing the opening,—if they do not prevent the valve from doing its duty, no symptoms (that I am aware of) can arise; so that the best auscultator in the world may find, after death, disease of the valves, of which he had no idea before the patient ceased to live. It is only when function is impeded, that any symptom can arise.

*Converted into Cartilage or Bone.*—The change which the valves undergo will, at last, amount to cartilaginous hardness. They will become perfectly cartilaginous; and, in a still further degree, they will become complete bone. When they undergo this change of consistency, the aperture of the part is diminished. In the case of the tricuspid valve, the opening may be reduced to one-third or one-fourth. Still, however, it generally retains its circular form. In the case of the corresponding valve on the opposite side (the mitral), the circular form is still in many instances retained; but in other cases the opening grows up in such a way, that it is only a chink. Instead of being circular, it is of a crescentic, or semilunar form; and, from the valve growing so considerably, a pouch is formed, leading from the auricle to the ventricle; so that on opening the left ventricle, a pouch is seen extending into it; and, at the end of the pouch, there may be a circular opening. Sometimes, instead of a pouch, the valves is all contracted together; and we have nothing more than a chink.

Sometimes the valves will become bony. When there is bone, it is deposited under the membrane,—it is deposited, as in all cases of serous membranes, immediately under it; and then the membrane, from the presence of the bone, becomes exceedingly thin; till at last it will disappear, perhaps, over the bony portion; and the bare bone is then in contact with the blood. It is very rare for the valve to be universally converted to bone, nor is it common for it to be universally converted into cartilage; but the changes exist in different degrees at different spots; so that here and there there will be bone, and sometimes the valves will become completely cartilaginous.

*Changes in the Auriculo-Ventricular Valves.*—The valves between the auricles and ventricles on either side,—the *tricuspid* on the *right* side, and the *bicuspid* or *mitral* on the *left*,—when they are much diseased, instead of falling back, form a very considerable curtain, with an opening (generally of an oval or circular form) in the centre of it. The different parts of the valve may become filled, or grown up; so that we have a complete membrane between the auricle and ventricle; and in the case of the *mitral* valve, especially, we every day see it extended in the form of a pouch. The opening in the mitral, as well as in the tricuspid valve, is generally in the centre, and is circular or oval. I before mentioned, that the mitral valve is sometimes so grown up, that a mere slit remains; and it is worthy of notice, that this slit is not straight, but is generally of a crescent form,—in the shape of a bent finger;—the concavity of the opening usually being towards the root of the aorta, and the convexity backwards. I believe the latter circumstance may be said to be universally the case. On looking from the auricle, the light is seen through the chink, in a very remarkable manner. I believe this observation was first made by Mr. Adams, a surgeon at Dublin; who wrote a very excellent paper on Diseases of the Heart, in the “Dublin Hospital Reports.”<sup>a</sup>

*The Pulmonary and Aortic Valves.*—With regard to disease of the other two openings of the ventricles,—the opening on the *right* leading into the *pulmonary artery*, and in the *left* leading into the *aorta*,—disease is more frequently found in the valves of the aorta, than in those of the pulmonary artery. This is according to the general rule, that all diseases far more frequently affect the *left* side of the heart, than the *right*. It is a rare thing, indeed, for the *pulmonary* valves to be much diseased; but if they are, the appearances are the same as when the *aortic* valves are affected. When the latter are diseased, they will stand quite firm; and

<sup>a</sup> Volume 4.

do not give way at all to the common pressure of the blood; so that the opening becomes diminished. The aperture which is left in the middle of the three valves, is sometimes circular; though occasionally it is triangular. It sometimes happens that these valves are completely converted into bone. They then form three shells of bone; but still they retain the appearance they present when there is only cartilage. It is very common to find bone about the aortic valves,—more common than anywhere else; but next in frequency we find it on the *mitral* valve. It is sometimes found at the *edge* of the valve; sometimes at the bottom of the *sac* of the valves; and sometimes there is bone on the aorta, *opposite* the valves. The quantity of bone is sometimes very great; and occasionally it occurs in minute granules, and not very firmly adherent; so that by rubbing it with the finger, portions come off in the form of grit.

*Warty Excrescences on the Valves.*—These changes are not the only ones, however, that we observe in the valves. Occasionally we find excrescences; and these are so much like venereal warts on the genitals, that Corvisart, who has written a very good work on Diseases of the Heart,<sup>a</sup> actually believed they were syphilitic. The appearance of warts on the genitals, does not depend upon their being syphilitic, but upon their being morbid growths of a particular structure; and we know that, in the greater number of cases, the warts depend upon mere irritation, without any other cause. These excrescences are very various in their appearance. Sometimes they are variously pointed, so as to exactly resemble venereal warts; and sometimes they are of very great length. I once opened a body, in which the excrescences were so long, that they nearly reached to the apex of the heart. It was the extremest case I have ever seen. There were a number of projections from the outside of the mitral valve; but it was at the roots of the *aortic* valves that they were so very long.

*Shrinking of the Valves.*—When the valves become so changed in various ways, they frequently shrink, and become shallow; and they also shrink in breadth. They also frequently become shorter, so that the aperture is altogether diminished; and when bone is deposited upon them, they frequently become brittle; and from their brittleness, they split and crack. The two valves frequently separate at the point at which they are usually united. They are no longer bound down, and the two are thrown into one; and at that point the valves frequently split to a greater or less extent. This is a very common occurrence. The valve is so corrugated, that the division between the two is lost. This is just the same occurrence that takes place in the interior of an artery, when bone is deposited there. An aneurism arises from the deposition of bone, and not from the mere coat of the artery. Bone is deposited in the middle of an artery, and the coat splits. In the case of the heart, it is not an artery that is affected, and therefore an aneurism is not produced; but the part splits in the same way. Dr. Baillie has given an excellent representation of some of these affections.

*Corrugation of the Valves.*—When the aortic valves become opaque, thickened, indurated, and rugged, they sometimes corrugate, so as to curl in towards the side of the aorta; and sometimes so as to turn out. Sometimes they are neither curled *in* nor *out*; but remain rugged. A paper was read at a society by a gentleman, announcing this as a very great discovery; but really it was no discovery at all. Corvisart's work contains a mass of information on Diseases of the Heart and Aorta; and is the best next to Laennec's on Diseases of the Chest. I recollect he states (without announcing it as any thing important) that sometimes the valves are folded *in*, and that sometimes they are folded *out*. Occasionally the induration is merely at the *roots* of the valve. On rubbing each, we find the root semicircular and hard. These are the chief varieties of disease of the valves.

*Comparative Frequency of Disease of the Valves.*—With regard to ossification, although it is seen so commonly in the *aortic* valves and the *mitral* valve, it is a very rare thing indeed to find the disease advancing so far upon the *right* side of

<sup>a</sup> "Essai sur les Maladies, et les Lésions Organiques du Cœur, et des Gros Vaisseaux."

the heart; but far more rare indeed to see it proceed so far upon the valves of the *pulmonary artery*. The tricuspid valve of the right side, is far more frequently diseased, than the semilunar valves of the pulmonary artery. Thus the aortic and mitral valves are not only far more diseased than those on the right side, but (to go to the latter situation) the tricuspid valve is more frequently diseased, than the valves of the pulmonary artery.

*Causes of these Changes.*—The changes to bone and cartilage, when they occur in young persons, are undoubtedly the result, in by far the largest majority of cases, of mere accidental inflammation; so that without having rheumatism, catching cold, or being exposed to the causes of inflammation, the individual would never have suffered from the disease. But when they occur in old persons, these affections can rarely, I believe, be traced to any particular attack of inflammation. They appear to be a degeneration of structure dependent upon age. Some parts of the body, under the influence of age, suffer transformations sooner than others; and this portion of the heart will become diseased, in old persons, really from a disposition to organic disease, and not from the result of accidental inflammation. This change of structure is common, in various parts of the body, as individuals grow older.

*Other Parts of the Membrane affected.*—Although the foregoing are the parts of the lining membrane of the heart, which are most frequently diseased, yet we occasionally see other parts of the lining membrane of the ventricles and auricles, but particularly the former, thickened very much, and hardened. Sometimes the lining membrane is particularly thickened where it lines the ventricles; while at the valves it is in a healthy condition. But this is an exception to the general rule. Now and then we see a little ulceration of this membrane; but that is a very rare occurrence.

*Deposition of Lymph on the Valves.*—There is one circumstance, which I do not find to be much dwelt upon in books; and it is, perhaps, the result of inflammation. Occasionally, after chronic pericarditis, there will be a deposition of lymph under the mitral or tricuspid valve; which will bind it completely down, so as to prevent it from fulfilling its functions. I have seen several instances of this occurrence. My attention was drawn to it by Dr. James Johnson; or probably I should not have known any thing about it. After I had published a case of this description, I found it had been incidentally mentioned, some years ago, in an account of the dissection of a body; but in the regular books on diseases of the heart, I do not recollect having been able to meet with any mention of the circumstance. It is well known that the tricuspid and mitral valves have a free floating curtain; and that if lymph be deposited between them and the heart, they may be bound down. A striking instance of the first of these affections, occurred to me; and I have never met but with three or four cases. I have given a representation of the case, in my work on Diseases of the Heart.<sup>a</sup> This was a case of common rheumatic inflammation. The woman had had rheumatism, several times. She had had disease of the valves; and also inflammation of the left ventricle.

### SECTION III.—EFFECT OF DISEASED VALVES ON THE FUNCTIONS OF THE HEART.

*Twofold Effect.*—We will now proceed to consider what effect these changes must have upon the functions of the heart. The effect may be twofold;—it may

<sup>a</sup> Plate III. The morbid appearances are thus summed up:—"The tricuspid valve thickened throughout; one half grown up, and completely adherent to the inner surface of the ventricle, with a hard rounded edge; the other half loose, and put upon the stretch, to show its extent, and the dimensions of the opening left during the play of the valve. The figure of the heart is altered,—being lengthened by hypertrophy and dilatation of the left ventricle; while the *right* ventricle—remaining healthy, and therefore reaching but a short way down—looks like an appendage to the *left*."

be to diminish the aperture through which the blood escapes from the auricles or from the ventricles; or it may prevent the valves from doing their duty, in offering an obstruction to the blood when it attempts to come back. Hence these changes may cause an obstruction to the blood going from the auricles to the ventricles, or from the ventricles to the pulmonary aorta; or they may prevent the valves from offering an obstruction to the blood, so that it rushes back, in some degree, from the ventricles to the auricles, or from the pulmonary artery or aorta into the ventricles. When the aperture is diminished, and the valves grow up, then there will be an obstruction to the transit of the blood; but very frequently the valves become so rugged, that they will not distend when the blood attempts to return; and therefore they can no longer perform the office of a valve. When the blood drives back against them, a portion of it goes through; though, of course, not the whole; because, whenever the valves are indurated and rugged, the aperture is diminished; and, at the same time that the diminution of the aperture prevents all the blood from going out that should do so, it prevents some from coming back that wishes to do so; and therefore there is not a *complete*, but a *partial* retrocession. Now the same thing will occur, if the valves happen to be bound down; but I have never seen the valve bound down, except in the case of the tricuspid; and I cannot conceive it possible that it can happen in the case of the semilunar valves of the aorta, or of the pulmonary artery; but if the aortic valves are corrugated, and are only half their size, then they can furnish no proper obstruction; and a quantity of blood will return. Thus disease of the valves may prevent the blood from going in a natural course; or they may allow it, in some measure, to come backwards.

*Natural Sounds of the Heart.*—These occurrences could not be known, formerly, in the living subject; but now that the ears are employed, they may frequently be detected during life. On placing our ear over the heart, or employing the stethoscope with one extremity placed over that organ, two sounds are heard. The first sound which takes place is rather long; and is immediately followed by a short sound: so that we have a double sound when the heart acts. The first sound which occurs at the moment of the impetus of the heart against the side; and the second immediately after it. The stroke of the heart and the first sound take place both together; and occur a little before the pulse at the wrist;—at least in most cases. Sometimes we cannot distinguish any interval at all, between the stroke of the heart and the pulse at the wrist; but very frequently we can; this interval arises from the distance of the radial artery from the heart. If we feel the artery nearer the heart, we find a less interval; if we feel the temporal artery, or the aorta itself, there is no interval at all. We may feel the aorta at the arch; and if you place one finger on that, and one on the heart, the stroke at each is found to be simultaneous. It is quite clear, that the pulse at the wrist is immediately consequent on the impulse of the heart. The second sound, which takes place after the impulse of the heart, always occurs, in health, after the pulse at the wrist; and the pulse of the wrist and the stroke of the heart are so close together, that in common language we may say they are simultaneous. Laennec supposed that the first sound of the heart took place from the contraction of the *ventricle*, and that the second occurred from the *auricle*;<sup>a</sup> and so he was able to predict where an obstruction would be found after death.

*Recent Investigations on the Sounds of the Heart.*—There is a difference of opinion, at this moment, as to whether Laennec was right in ascribing the second sound to the contraction of the auricle; and I am inclined to believe that he was wrong. My reason is this. On passing the stethoscope over the heart of a jack-ass, when the heart was laid bare,—according to the experiment of Dr. Hope,—I heard the second sound when the stethoscope was placed upon the ventricle. The sound clearly came from the ventricle; and I was told by others who could see what happened, that the auricle did not contract at that time. But although I dare say

<sup>a</sup> See Dr. Forbes's Translation of his Treatise on Diseases of the Chest; Part 2; Book 1; Chapter 4; Paragraph 1. (Third Edition; Page 558.)

the sound did not arise from the mere contraction of the auricle, yet I have no doubt that it took place at the very moment when the blood passed from the auricle into the ventricle; because, as soon as the two ventricles have contracted, they dilate; and the instant they dilate, the blood must rush into them. A vacuum is formed by the dilatation; and the blood must rush out of the auricles into them; and I believe this is a passive circumstance. The contraction of the auricle appears to have little to do with it. When the ventricle dilates, the auricle empties itself; but, as far as I could observe in the experiment made, it does this in an irregular manner.

[These experiments were afterwards repeated and varied by the Dublin Committee of the British Association for the Advancement of Science; and, more recently, an extended series of experimental researches, on the same subject, has been conducted by Drs. Clendenning, Todd, and myself,\* in another committee for the same association. It was decided unequivocally, by all the series of experiments alluded to, that the first sound accompanies the whole duration of the systole of the ventricles, which also causes the impulse felt on the walls of the chest; it was equally clear that the second, or flapping sound, occurs at the first moment of the diastole, and that the motion of the auricles was not accompanied by any perceptible sound.

*Production of the First Sound.*—How does the contraction of the ventricles produce the first sound? Sound may be defined to be “*motion of a certain force, resisted with a certain force:*” where is the resisted motion in the contraction of the ventricles? One of the first ideas that suggest themselves, is that of Magendie: does not the heart produce the impulse by striking against the walls of the chest? and why should this not cause sound? In forcible pulsations, and when the lung does not too much intervene, I have no doubt that the impulse does produce sound; and if we listen to the sound of the heart when it is beating strongly, or when, by leaning forward or by breathing out, the heart is brought in contact with the walls of the chest, we hear the first sound has in it something like a knock, which we can scarcely help referring to the impulse. But this is an *accessory*, and not an *essential* sound; for we may hear the first sound when there is no impulse;—as in a person leaning backwards, or taking a full breath; and, in our experiments, we heard the first sound at the origin of the arteries, when the body of the heart was surrounded with the soft lung or with tow; or was allowed to hang out of the chest, and strike against nothing in its motions. It is well known, that liquid in the pericardium, or liquid or air in the pleura, although it entirely prevent the heart from striking the walls of the chest, does not annul the first sound. In moderate pulsations, the heart makes a partial rotatory movement: the long fibres of its anterior convex surface, drawing the apex upwards and forwards, and causing it to slide obliquely on the smooth pericardium, bring it to the walls of the chest too gently to produce sound, except in the circumstances before mentioned.

The first sound, then, is produced by something in the heart itself;—either by its contents, or by its own structure. Can it be by its contents;—by the motion of the blood resisted by the inequalities of the interior of the ventricles? This was supposed by the Dublin Committee to be the chief cause of the sound. But the motion of the blood over these inequalities is not rapid, nor is their resistance considerable at the time of the production of the sound. These inequalities are, as Dr. Cowan has pointed out, chiefly confined to the lower or auricular portions of the ventricle, into which the blood has already passed before the systole begins; and the effect of the systole is to drive the blood, not over or across the inequalities, but from them, to those smooth and funnel-shaped parts of the ventricle which lead to the arteries, and which offer the least possible resistance to its course. The contraction of the ventricles propels the passive mass of blood gradually—that is, during the whole period of the first sound—into the arteries; and the motion is therefore too slow and easy to be likely to cause sound. Some of our experiments further settled this point; by proving that the first sound continued when the ventricles contracted without any blood in them.

\* Dr. C. J. B. Williams.

By excluding the blood we are thus brought to the conclusion, that the cause of the sound must be in the solid structure of the ventricles: it is our next question, whether it be in any part of them in particular. Several writers have ascribed it to the auriculo-ventricular valves; which, when they close, are supposed to produce a flapping sound. But the act of closing these valves is momentary, and takes place only at the commencement of the systole; whereas the first sound of the heart is prolonged through its whole duration. Further: in some of our experiments the first sound continued, although impaired, when the auriculo-ventricular valves were prevented from acting, by fingers introduced into their orifices, or by some of their cords being *hooked* back or cut. Still these valves no doubt produce a part of the sound; for at each contraction they are suddenly tightened, in a manner calculated to generate sound.

But are the valves the only parts which are tightened at each systole of the ventricles? Is not every muscular fibre in the ventricles suddenly tightened by this action? Here are the elements of sound, motion vigorous and rapid, suddenly resisted by the mass of blood to be urged forwards by the contraction; and the contracting motion and the resistance, although greatest at first, continue to act as vibrating forces during the whole systole: hence the prolongation of the sound. In other instances, abrupt and forcible muscular contraction produces a sound like the first sound of the heart; as when we apply the stethoscope to the adductor muscle of the thumb of the closed hand, and contract the muscle strongly and quickly. Or, to avoid the possibility of the joints being the seat of the sound, if we apply the end of a flexible tube to the abdominal muscles, and start them into sudden vigorous action, we may thus get sounds quite as loud as those of the ventricles, and very like them in character.

By varying the mode of this muscular action, different kinds of sound may be produced. When the contraction is slow or sustained, however strong, we have only the dull rumbling noise which Dr. Wollaston first described; and which he attributed to the vibration, depending on a regular intermittence in the force of the contraction. When the contraction is gentle and slow, it may cause no sound at all; as the auricles generally produce no sound, neither do the ventricles, when their contraction is very feeble. But whenever there is strong abrupt muscular action in any part of the body, like that of the heart, there will be heard a sound which will resemble that of the ventricular systole, in proportion as the muscles in which it is produced resemble in thickness and density the tissue of the heart. The loudness of the sound is by no means in proportion to the thickness or strength of the muscle; but rather to its simplicity, and the abruptness as well as the vigour of its contractions: the transition of a thick muscle from slack to tight, can never be so complete and sudden as that of a thin one; where there are many fibres, they choke or muffle each other's vibrations; hence the sound is dull and prolonged, rather than loud and clear. Many writers who have objected to my explanation of the first sound of the heart, have done so in ignorance of the principles on which muscular action causes sound. When these are known, the identity of the phenomena becomes apparent; and, in my experiments,\* there was the best proof we could have, that the muscular contraction of the heart produced systolic sound; for we had the heart out of the body, without its blood, without valvular action, lying on the table, or on my hand; and its contractions were still accompanied with a sound, weak indeed, but in character resembling its natural first sound.

The walls of the ventricles appear to be peculiarly calculated to generate sound. Their flaccid state when relaxed, the fineness of their fibres, and the harmony with which they suddenly contract on their contents, and become almost as hard as a stone (as we feel in the living heart of a stunned animal), fulfil the conditions best calculated for the production of sound. The commencement of the systole—producing the tightening of the auricular valves, and thereby completing the resistance of the body of blood on which the contracting fibres have to act—is naturally its

\* Those of Dr. C. J. B. Williams.

loudest part, and often has a flapping character; that which continues after is more dull, and is prolonged according to the quantity of blood to be expelled, and the continued strength of the contraction. This prolonged termination of the sound is, therefore, best heard when the heart acts slowly and vigorously.

*Production of the Second Sound.*—What causes the second sound? That it is intrinsic, and not caused (as Magendie supposed) by the heart striking any of the surrounding parts, we proved by the same experiments in which the intrinsic character of the *first* sound was shown: the sound continued when the heart was so completely isolated that it could strike against nothing.<sup>a</sup> What is there, then, within the heart, that can produce this short clapping sound at the moment of the diastole? Is there any thing that tightens at that moment? Not the walls of the ventricles certainly, nor the auricular valves; for they are then all loose and flaccid. What can it be but the semilunar valves at the mouths of the arteries; which are then suddenly tightened by the reaction of the arterial column of blood? And so it was proved to be, in my experiments first, and in many repeated since; for by hooking back these valves, or by pressure preventing the reaction of the column of blood upon them, the sound was stopped; and by releasing the valves, or discontinuing the pressure, the sound was as surely restored.<sup>b</sup>

We may consider it, then, as established, that the *first* sound of the heart is produced essentially by the tightening of the valves and walls of the ventricles, by muscular contraction; and that the *second* sound is caused by the sudden tension of the arterial valves, by the recoil of the arterial column of blood upon them.<sup>c</sup>

*Abnormal Sounds of the Heart.*—The nature of those sounds which occur in health, need not be described: because we have only to place a stethoscope, or our ear, over a friend's chest, in the region of the heart, and we shall immediately perceive them. But if there be an obstruction,—so that the blood cannot pass freely out of the left ventricle into the aorta, or from the right ventricle into the pulmonary artery,—then, in most instances, there is an alteration of the sound. If the mouth of the pulmonary artery, or of the aorta be obstructed, a similar effect is produced to that resulting from the arch of a bridge being narrowed; so as only to permit the stream to pass through it at a certain pace. The stream passing through a narrowed arch, makes a whizzing sound, which was not heard before; and so if the blood, while passing from the ventricles into the pulmonary artery or the aorta, meets with an obstruction, it produces a sound not heard in health. This sound occasionally resembles that produced by a pair of bellows; and is therefore called “a bellows-sound;” or, in French “bruit de soufflet.” Occasionally it is shrill, like the action of a file; and then it is called “a rasping sound,” or “bruit de râpe.” Sometimes it is like the action of a *fine saw*; and then it is called “bruit de scie.” Perhaps the term “*preternatural sound*” would be a good generic term for embracing all these sounds. I have so used it, in my work on “Diseases of the Heart.”

*Causes of these Murmurs.*—[An example or two will set before us something of the character and causes of these murmurs. At the moment when the blood is issuing from the ventricle, if—instead of a smooth, equally tense channel—it meets with a rigid constriction, or an abrupt orifice, its passage through it will be attended with a whizzing or blowing noise, which may be heard in the region of the heart. Or to take a simple case: if we apply the stethoscope in the course of an artery far from the heart, we hear nothing as long as the current of blood flows smoothly and unmodified through it; but if by pressure we diminish the calibre of the tube at any point, we then complete the elements of sound: we give resistance to the

<sup>a</sup> See Page 837.

<sup>b</sup> Dr. Carwell seems to have been the first who conceived, that the second sound is caused by the flapping of the semilunar valves. He was led to this opinion by observing the signs of a case of aortic aneurism in 1829; a drawing of which is now in the Museum of University-College, London. The first proposal of this explanation that I know, of in print, is in a thesis (“De Corde”) by Dr. Elliott, Edinburgh, 1831. Dr. Billing, M. Rouanet, and Mr. Carlile, were later advocates of this view.—Dr. C. J. B. Williams.

<sup>c</sup> Dr. C. J. B. Williams, on the Chest; Fourth Edition; Pages 204 to 208.

moving blood; and, at each pulse, we hear a blowing or a whizzing sound; which will vary in tone and loudness, according to the force of the current, and the degree of resistance which it meets with. This is purely a physical phenomenon; it may be produced in any tube through which a current of water runs. Thus, if we take an india-rubber tube, and adapt it to a reservoir of water,—so that the water shall flow freely through the tube, we may by pressure on the tube produce murmurs, varying according to the force of the current, and the resistance which the pressure opposes to it. They are sometimes like blowing; sometimes like rasping or sawing a piece of wood; and now and then they may be heard in quite a musical tone, which implies that the vibrations are then regular and sustained. The blowing and musical murmurs are generally caused by greater regularity, but less force of current, than that which produces the sawing or whizzing sounds.<sup>a</sup>]

*Obstruction of the Auriculo-Ventricular Opening.*—If the obstruction be between one of the auricles and the corresponding ventricle, then it is the *second* sound which is altered; and it is after the beat of the heart,—after the pulse at the wrist, that we hear this preternatural sound;—whether it be a *bellows*, a *sawing*, or a *filing* sound.

A vacuum cannot be formed in the *ventricle*, without the blood escaping from the *auricle*; and therefore when there is an obstruction between the auricle and ventricle, a bellows-sound is heard at the moment we should hear the second natural sound of the heart. We may form an accurate diagnosis in this way. I have done it over and over again; and have always predicted the exact part where the obstruction existed. I have always taken it for my guide, that where a bellows-sound was heard at the moment of the stroke of the heart against the side, there was an obstruction, either at the mouth of the *pulmonary artery*, or at the mouth of the *aorta*; and, on the other hand, where a bellows-sound has been heard *after* the first natural sound, that then there has always been some obstruction to the course of the blood from the auricle into the ventricle; or else that the valves at the mouth of the aorta, or of the pulmonary artery, have not done their duty; so that the blood has partly rushed back into the ventricle. Whatever may be the cause of the second sound heard in the heart in health,—whether the dilatation of the ventricle or not, it is at that moment that we hear the bellows-sound, when there is an obstruction to the course of the blood from the auricle to the ventricle.

*Period at which the Blood leaves the Auricles.*—Laennec states, that at the moment of the pulse at the wrist,—at the moment of the stroke of the heart against the side, the blood leaves the ventricles, and rushes into the pulmonary artery and the aorta;<sup>b</sup> and that it is immediately after this, that the blood leaves the auricle, and rushes into the ventricle;—so that the first sound of the heart occurs at the moment of the stroke of the heart, and the pulse at the wrist, or just before it,—the difference being exceedingly minute; and depends upon the rush of the blood from the ventricle; and the *second* sound depends upon the rush of the blood into the ventricle from the auricle. It perhaps may be doubted whether, in the latter case, it arises from a contraction of the auricle; but I think there can be no doubt it takes place at the *period* he mentions; though, in all probability, it arises from the flow of the blood out of the one cavity into the other. It has been said, that if we inspect the heart of a living animal, we see that the auricle contracts before the ventricle;—the reverse of what Laennec has stated. This, certainly, I have seen. But it is to be considered, that the muscular part of the auricle is very inconsiderable; that the greater part is a mere venous sinus; and, I imagine, it must be when the ventricle is dilated, that the blood rushes into it. Now the ventricles dilate the moment after they have contracted; and therefore I should conceive, that this rush of the blood from the auricle, is an effect independent of the *contraction* of the auricle;—that it is merely the effect of a vacuum produced in the ventricle by its dilatation; so that the blood rushes on, as it does from the “*venæ cavæ*.” In the experiments I saw, the auricle contracted with great irregularity;—sometimes *before*

<sup>a</sup> Dr. C. J. B. Williams, on the Chest; Fourth Edition; Pages 215 and 216.

<sup>b</sup> See Note to Page 836.

the ventricle, sometimes *after* it; and I have seen five or six contractions of the auricle, to one of the ventricle; so that I do not think the ventricle is filled by the action of the auricle. Another great argument is, that I have been able to make an accurate diagnosis, by observing the periods of the morbid sounds, as Laennec has stated them. Whenever there has been a contraction of the mouth of the aorta, or of the pulmonary artery, the preternatural sound—whether it has been a *bellows*, a *sawing*, a *rasping*, or a *cooing* sound—has been at the moment of the stroke of the heart. Whenever the tricuspid, or the mitral valve, has been diseased,—when ever I have seen the opening between the auricle and the ventricle (or either side) contracted or narrowed, then the morbid sound which I have heard has always been *after* the pulse,—*after* the stroke of the heart;—showing that it is at that time the blood leaves the auricle; that is to say, it is as soon as the ventricles have emptied themselves and dilated again.

*Case of Dr. Hopkins.*—Details have been published of a post-mortem examination, which took place abroad. It was the case of Dr. Hopkins, who was formerly a lecturer at Mr. Grainger's Medical School, Webb Street, Southwark. It is stated, that the left ventriculo-auricular opening of the heart was ossified, in its whole circumference, for three lines in breadth; and that there was a singular contraction of the opening. It so happened that this gentleman came to me, about six months before his death, with œdema of the lower extremities, and difficulty of breathing. I examined his chest; and, in a moment, found signs of a dreadful disease of the heart. I made pretty extensive notes of the case, at the time; and, founding the diagnosis on what Laennec has said, I stated there was disease of the mitral valve. In that case, I heard a very extraordinary sound, immediately after the stroke of the heart. It was not a bellows-sound, but a variety of preternatural sounds, and sometimes there were two or three of them in rapid succession. It occurred immediately after the pulse; and was heard on the left side of the heart's region. When I listened with the naked ear, instead of this extraordinary sound, it appeared like the sound of a saw. I did not doubt that he had disease of the mitral valve; or, if they were not an obstruction to the course of the blood from the auricle into the ventricle, that the aortic valves were so diseased, as to let a little blood come back. I therefore wrote down in my note-book—"Disease of the mitral valve, or else imperfect action of the aortic valves." If Laennec be wrong, the sound I have described ought to have been heard at the moment of the heart's action. But here is a dissection taking place in a foreign country, by a person who knew nothing of me or of my diagnosis; and here are the post-mortem examination, and my written account of the state of the heart, corroborating each other. This shows us, as more than twenty or thirty cases have done before, that Laennec is right. He may be wrong in saying that the auricle contracts then; but I cannot consider him incorrect in saying that the blood rushes, at that moment, from the auricle into the ventricle. Some ascribe the sound to the circumstance of the ventricle dilating; but I am not aware that it gives a sound. I should think it more likely that it is owing to the rush of blood into the ventricle. I regretted, when Dr. Hopkins went abroad, that I should not have an opportunity of comparing the dissection with the diagnosis; and therefore I was gratified when I saw the case published.

*Cause of the Preternatural Sounds.*—Why it is that we have sometimes a bellows-sound, and sometimes a sound resembling the action of a saw or a file, is not well known. Some have supposed, that ossification gives rise to the shrill sound; but that is not proved. It depends, I should imagine, on two or three things in conjunction. If the opening be very small, and the action of the heart be driving on a large quantity of blood, I should think it would be shrill; but if the opening be small, and the action of the heart not very strong, then the feeble influence of the blood will, I should think, not cause the shrill sound. If the parts were soft, then we might have a shrill sound.

*Does the Auricle Contract First?*—It has been supposed that the auricle contracts before the ventricle,—for this reason;—that, in the case of an obstruction, the jugular veins swell at the time of the stroke of the heart. Before the pulse is

felt, indeed, the jugular vein will sometimes swell, in disease of the heart; and will pulsate strongly. It is supposed, that when the auricle contracts, an obstruction must take place in the veins, and the blood accumulate there. For myself, however, I do not think that, at the time the auricles contract, there is any obstruction in the veins; for when they lose their blood, the ventricles must be open for the blood to rush into them; and, consequently, there is a free passage for the blood. When the ventricle is *contracting*, there must certainly be a great obstruction to the blood; but the moment the ventricles *dilate*, that moment the auricles act; and the action of the *auricle* cannot cause an obstruction, because there is a free course for the blood to rush into the *ventricle*.

Laennec's accuracy has been again called in question by others; and the stroke of the heart's apex, and the *first* sound of the heart, have been declared to happen before the pulse; and to be produced by the *dilatation* and *repletion* of the ventricle; and the *second* sound has been said to occur at the moment of the *contraction* of the ventricles, and to arise from the flapping together of the parietes of the emptied ventricles.

I would reply, in the first place, as before,<sup>a</sup> that when an obstruction exists at the mouth of the *aorta* or *pulmonary artery*, a morbid sound occurs at the moment when Laennec supposes the *ventricles* to contract; and when an obstruction occurs at either *auriculo-ventricular* opening, a morbid sound occurs at the moment he supposes the *auricles* to contract. This could not happen had he mistaken the periods of the ventricular and auricular contractions.

Secondly: when the pulse at the wrist follows the stroke of the heart, it does so after only a very minute interval;—such as may be explained by the distance of the radial artery from the heart; and actually occurs decidedly *before* the auricular sound;—that sound which is now declared to be the *ventricular*. Moreover, when the pulse of the wrist is observed to follow the stroke of the heart, the pulse at the innominate (so much nearer the heart) may be found to precede that at the wrist, and to occur all but simultaneously with the stroke of the heart; so that the relative distance of the parts explains the whole difference; and the pulsation of the arteries, in all cases, clearly arises from the stroke of the heart. If an artery still nearer the heart than the innominate be observed, *no* interval between its pulse and the stroke of the heart is perceptible. In four cases of aneurism of the ascending aorta, producing a strongly pulsating tumour to the right of the sternum, this and the heart, when the fore-fingers were placed upon both, were felt, and by all seen, to pulsate quite synchronously. When the obstruction is at the mouth of the *aorta* or *pulmonary artery*, I have always noticed the preternatural sound to be *synchronous* with the pulse;—when at an *auriculo-ventricular* opening, in the *intervals* of the pulse, *after* or *before* the pulse. Sometimes in the latter case, it is so prolonged, as to last till the pulse is again felt; so that there is no interval; but merely an equal alternation of the ventricular, and the preternatural auricular sound: or even an interval occurs after the ventricular stroke;—probably from the auricle not being disposed for contraction at the usual time; on account of its contraction having been so lengthened by the difficult escape of its blood, that a longer repose is required, than just during the ventricular contraction. Here the *auricular* sound occurs first; then the *ventricular*; and then the *interval*.

Thirdly: the sounds considered by Laennec to be auricular and ventricular, are heard loudest (both in health and when morbid) at the seat of the auricles and ventricles respectively.

*Cause of Preternatural Sounds after the Pulse.*—When these peculiar sounds are heard a moment after the pulse, and after the action of the heart, we cannot say with certainty, that they arise from a difficulty to the transmission of the blood from the auricle; and for this reason. If the valves at the mouth of the pulmonary artery and aorta do not do their duty, but allow a portion of the blood to regurgitate, (as is very common in the case of the aorta,) I believe the rushing back of a small

<sup>a</sup> See Page 839.

quantity of it, will occasion the bellows-sound. We know, that the moment the ventricle has acted and dilates again, the blood attempts to rush back into the vacuum; but is prevented by the three aortic valves, which are filled out in a moment. But if it so happen that one is torn, or becomes corrugated and small, then a certain portion of the blood will regurgitate; and as it is not the *whole* of the blood in the aorta that can go back, but a *minute portion* that passes through the small opening which is left, (the valves doing their duty to some extent,) that is sufficient to cause the bellows-sound. If the *whole* of it regurgitated, doubtless there would be *no* bellows-sound; but if only *one* valve be torn, or corrugated, or if the whole of the valves be *partially* corrugated, then the small portion which returns causes the bellows-sound. This must take place synchronously with the emptying of the auricles. The same cause which makes the blood rush from the auricles,—namely, the dilatation of the ventricle,—also attempts to make the blood rush back from the aorta and pulmonary artery into the ventricle. The blood attempts to go from the *auricles*, and does so with success; and at the same instant it attempts to do so from the *aorta* and *pulmonary artery*, but cannot; and it is at this moment that we have the morbid sound. Suppose it is one of the auriculo-ventricular openings that does not do its duty;—suppose the tricuspid valve on the *right* side, or the mitral valve on the *left*, is bound down on one side; or suppose it is diseased, so that there is a constant aperture there, through which a certain portion of blood must rush back from the ventricles into the auricles;—then we have a bellows-sound, from this cause, at the time the ventricles contract. I have frequently heard a bellows-sound, at the moment of the pulse;—arising, not from an obstruction to the course of the blood out of the ventricles, but from a valve between the auricles and ventricles not doing its duty; so that a small portion refluxed.

Before I was aware of this circumstance, in one or two cases, I gave a false diagnosis; and said that there was an obstruction to the course of the blood from the ventricle; whereas it turned out that the valve between the auricle and ventricle was not performing its functions properly. Hence, when there is a bellows-sound at the moment of the heart's action, it may arise from disease of the *aortic* valves, or from disease of the *mitral* valve; and when the bellows-sound takes place *after* the pulse, it may be the result of an obstruction to the course of the blood from the *auricle*, or from a certain portion rushing back into the *ventricle*. In every case, it is caused by one of these two circumstances.<sup>a</sup> The first case in which I found I had made a false diagnosis, was one which I have already described.<sup>b</sup> The preparation is at St. Thomas's Hospital. There was a loud bellows-sound at the moment of the pulse; and I therefore concluded, that there was an obstruction at the mouth of the aorta, or of the pulmonary artery. But I found that the mitral valve was bound down; so that there was a constant opening; and, when the ventricle contracted, the blood refluxed freely into the auricle.

*Causes of Diminished Apertures.*—These diminished openings may occur from various causes. Sometimes the valves are diseased in the way I have mentioned. The valve may be indurated, become cartilaginous,—become bony; and the opening may be organically diminished. The aperture is sometimes decreased by excrescences. Twice I have seen the valves perfectly sound, and the pulmonary artery contracted immediately beyond the valves; so that only a very minute aperture existed, for the blood to escape through. In one of these cases the disease arose (as it does in so many instances in young persons) from violent pericarditis. The pericarditis had gone on to produce cartilage under the pericardium; and the

<sup>a</sup> [Recently it has been established by Hope, Pennock and others, that these sounds are distinguishable by the following circumstance, viz., that the sounds generated in the mitral valve are loudest at the point of the heart, whilst those of the aorta are best heard over the region of its valves, *i. e.* over the sternum opposite the third rib. T. S.]

<sup>b</sup> See Page 835.

cartilage had dipped down so much into the substance of the heart, that it pressed upon the origin of the pulmonary artery, and there produced a great obstruction. In that case there was a bellows-sound, heard at the moment of the pulse. I heard it on the right side of the heart's region, in the situation of the right ventricle; and it was written down in the hospital-book—"Difficulty to the transmission of the blood from the right ventricle to the pulmonary artery." What the cause was, I did not know.<sup>a</sup> I have met with but two cases of obstruction of the pulmonary artery. Disease of its valves is exceedingly rare. In fact, all diseases are far less common on the *right* side of the heart than on the *left*. In the second case the diagnosis was equally correct. There was a loud bellows-sound on the right side of the heart, at the moment of the pulse; and after death just such a disease was found as I have now described;—that is to say, the pulmonary artery was so diminished, that the blood could not escape from the ventricle.

There is an engraving in my work,<sup>b</sup> of a case which I did not see; and therefore I do not know what the particular symptoms were; but there was a loud bellows-sound. Part of the interior of the right auricle and ventricle was grown together round the mouth of the pulmonary artery; leaving a very small opening, beyond which was the real mouth of the artery, of its natural size, with its valves. The case occurred at St. Bartholomew's Hospital; and the heart was shown me when lecturing at the College of Physicians. The patient was a young woman, and died from this affection. I should think it was a case of malformation; because I did not perceive any sign of disease of the heart. She was dropsical all her life; and, at last, there were signs of great obstruction. The older she grew, the more the heart increased in size; but the opening never enlarged. There were more and more ill effects the longer she lived. These are very rare cases indeed. If any thing press upon the aorta, or upon the pulmonary artery, we have this bellows-sound;—although there may be no disease of the vessel itself,—no disease of the valves,—no disease of the opening. I recollect seeing a case, where there was a piece of bone between the aorta and the pulmonary artery; and it pressed on both. There was a bellows-sound at the time of the pulse, on both sides of the chest. A case is mentioned by Bertin, where a sort of hymen existed at the mouth of the pulmonary artery; but it was probably congenital; and this is the only instance of obstruction, that he ever saw at that spot. I have never seen obstruction from disease of the pulmonary semilunar valves. Bertin refers to two;—one in Morgagni, and one seen by M. Louis at La Charité.

*Preternatural Sounds from Dilatation.*—We may have a preternatural sound, however, while the opening remains quite natural. The cavity *behind* the opening is very much dilated; and in that way the opening is *relatively* small, although not *absolutely*. Nature, of course, has established an exact proportion between the size of the *openings* and that of the *cavities*: and the natural dimensions are those which allow the blood to pass through in the most easy manner, and with the least noise. Thus, the natural proportions may be destroyed in two ways. The cavities may remain the same, and the openings become too small; or the openings may remain the same, and the cavities become too large. In the latter case, the openings are no longer large enough for the cavities; and in either case we have the bellows-sound. We must not be surprised, therefore, after a bellows-sound, to find the openings in a natural state; because the cavity may be too large. Nay, when this is the case, the least alteration in the position of the heart, will sometimes

<sup>a</sup> Through an oversight, the specimen was allowed to putrefy; and the whole was destroyed, except (fortunately) the portion of the right ventricle at which the artery rises, the semilunar valves, the commencement of the artery, and the cartilaginous mass. Besides various symptoms from pulmonary and other cardiac disease, there had been a bellows-sound at the lower part of the sternum and to the right of it at the moment of the pulse. The production of cartilage originated in pericarditis. The pericardium was throughout coherent and thickened, and was cartilaginous in several other points than where the great mass existed.

<sup>b</sup> "Lectures on Diseases of the Heart;" Plate 2; Figure 2.

cause a bellows-sound; and, by position, the free course of the blood from the left ventricle may be destroyed. I once had a very curious case of this kind.

*Case.*—A woman laboured under ascites; the cause of which I was anxious to discover; and also to ascertain, whether there was organic disease. I examined the heart, and found a bellows-sound at the moment of the pulse. She was tapped; and no sooner was the operation performed, than the bellows-sound went away. The water accumulated again, and with it the bellows-sound returned. In this case, after death, the opening was found healthy; but the left ventricle was dilated. It appeared to me, in that case, that the diaphragm, being pushed up by the water, tilted the heart a little,—prevented it from being quite in its natural situation; and caused the apex to rise in such a way, that the passage of the blood into the aorta would be a little impeded. If the position of the heart be altered,—if the apex be lifted up, no doubt the blood will experience a difficulty in going into the aorta. In this case, when the heart was pushed up (with the diaphragm) by the water, there was a bellows-sound; and when the diaphragm was let down,—the heart going with it,—the bellows-sound ceased.

In any case where a bellows-sound is heard at the moment of the pulse, we *may* find pressure from the abdominal viscera. When a person is upright, and the bellows-sound takes place at the moment of the stroke of the heart, if we make him lie flat, the bellows-sound is increased;—owing to the abdominal viscera pressing up, and the apex becoming a little tilted. I have frequently not heard the bellows-sound at all, when a person labouring under disease of the heart has been standing up; but on making him lie down, I have heard it distinctly. It is better, therefore, in these cases, to listen to the sound in both ways. When a bellows-sound is heard in the case of the aorta, I presume the circumstance arises from the same cause. When a person lies down, the abdominal viscera press against the diaphragm, and alter the position of the heart; so that the blood cannot so easily escape from the aorta. We know that when there is difficulty of breathing, patients wish to sit up; and then the heart falls more into a vertical position. In hypertrophy of the heart, a bellows-sound is frequently heard where there is no great dilatation. If it so happen that the substance of the heart is much thickened,—that the “columnæ carneæ” are much thickened near the mouth of the aorta (towards the semilunar valves,)—the increase of the flesh of the heart will cause a little obstruction; so that we have a bellows-sound. Frequently, therefore, in opening bodies where there has been a bellows-sound, we find some other cause than disease of the opening. We may find something pressing on the outside of the aorta;—we may find the substance of the heart increased;—we may find the heart out of its due position;—we may find the cavity behind the opening so much dilated, that the latter, although of its natural dimensions, is not capacious enough for the enlarged cavity which forces its blood through it.

*Bellows-sounds sometimes Temporary.*—It would appear that sometimes the bellows-sound is only a temporary phenomenon, dependent upon spasm or irritation. Sometimes there would appear to be a spasm in the neighbourhood of the opening; for a person will have a bellows-sound one day, and not another. It is said that hysterical women sometimes have this bellows-sound; and they have spasmodic affections of various parts.

*Bellows-sound affected by Blood-letting.*—Frequently, by taking blood away, we diminish the bellows-sound, and even remove it altogether. If we lessen the quantity of blood that has to go through the opening, there will be less obstruction felt; and therefore, by bleeding to a certain amount, we diminish (or, it may be, entirely remove) the bellows-sound. Sometimes, in inflammation of the heart, this bellows-sound is heard; and, on subduing the inflammation, it may never return. In this case, the parts may be thrown into a spasmodic state;—just as, when the urethra is inflamed, a spasmodic stricture may take place;—so that no water can pass; and, on bleeding the patient, the affection is removed. So, I conceive, it may happen with the opening of the heart. Again: the bellows-sound will be heard if we bleed a patient *too much*. We may bleed a patient till we get a sharp pulse; and

then we may be led to suppose that inflammation exists, although the person may be blanched like wax. Now, when a patient has been thus reduced, I have been told by many that a bellows-sound has been heard. I presume that, in this case, the bellows-sound arises from the violent action of the heart. It attempts to drive the blood away faster than it can go with ease. We may, however, have a bellows-sound simply from great *plethora*. There is such fulness of the heart, that the blood cannot escape through the opening; and, on the other hand, we may have such a rapid action of the heart, that more is attempted to be forced through it than the opening will allow.

*Mode of Using the Stethoscope.*—In observing these morbid sounds, we should use the stethoscope without the plug. Laennec does not mention the circumstance; but if we examine the sounds of the heart with the plug in the stethoscope, and then take it out, we shall generally hear the sounds far louder without the plug. I am quite sure of this. I have proved it myself, and mentioned the circumstance to others; and they have always said they found it to be the case. It is right to examine a patient labouring under disease of the heart, with the plug *in* as well as *out*; because, when the plug is in the stethoscope, we have a larger surface for the heart to strike against. Laennec employed the stethoscope in its entire state, to examine the heart; and the presence of the plug is certainly advantageous in ascertaining the *impulse*. But for observing the *sounds* of the heart, the instrument is much better without the plug. The excavation renders the sounds far more audible. It is often very useful to make the patient suspend his breath for a few moments, while we are listening to the sounds of the heart. The murmur of respiration is often mistaken for a cardiac bellows-sound; and in dyspnœa, the sounds of the lungs sometimes completely overpower those of the heart.

#### SECTION IV.—GENERAL SYMPTOMS OF OBSTRUCTED CIRCULATION.

*Dilatation of the Auricles.*—There are, of course, other symptoms induced, besides those which are to be learned by the ear. If there be any difficulty in the transmission of blood through the heart, the cavity behind is very much disposed to dilate. The blood not going out with ease, accumulates; and gradually causes a dilatation. This is a very common circumstance; but it is a curious fact, that we do not always have the dilatation in the cavity immediately behind the obstruction. The auricles, being much thinner than the ventricles, more easily become dilated. The effect of an accumulation of blood, is frequently felt at a great distance from the seat of the obstruction. When the mouth of the aorta is obstructed, sometimes the left *ventricle* is dilated; but more frequently it is the *auricle*; and even the *mouth* of the auricle. In disease of the mitral valve, of course we cannot expect dilatation of the left *ventricle*, because it is beyond the obstruction; but we may expect dilatation of the left *auricle*,—and dilatation of the *right* auricle, or even of the *right ventricle*; because all these parts are *behind* the obstruction, wherever that obstruction may be.

*Pulmonary Congestion.*—When there is an obstruction at the left side of the heart, either at the mouth of the aorta or at the auriculo-ventricular opening, the obstruction is shown particularly in the lungs. Dr. Wilson, of St. George's Hospital, has mentioned that he has frequently seen what is called "apoplexy of the lungs,"<sup>a</sup> after an obstruction of the mitral valve. We continually meet with an obstruction of the mitral valve, without any such circumstance; though certainly it will very frequently happen; but in almost every case, there is great congestion of blood in the lungs; and this soon shows itself in the whole of the venous system. The obstruction is soon felt beyond the lungs, on the right side of the heart.

*Congestion of the Venous System.*—Of course any obstruction on the *left* side,

<sup>a</sup> See Page 763.

can only act on the system at large. If the blood do not escape easily from the pulmonary veins, it accumulates in the lungs, and therefore will not pass freely out of the pulmonary artery; then the right ventricle suffers, and all the venous system. The consequence of all this, is great fulness of the veins of the neck, frequently of the head, and sometimes of all the veins of the body;—and then general dropsy;—not only a swelling of the ankles, and œdema of that part; but *general œdema*, which is called “anasarca,”—universal dropsy.<sup>a</sup> And then, from the great accumulation of blood in the head, there is headache and drowsiness, and perhaps apoplexy;—effusion into the brain and upon the brain. The patient's countenance is blue; his lips are pale; and perhaps the nose and eyes look exceedingly livid. In many cases of this description, effusion is first of all seen about the eyes, particularly the lower eye-lid. Indeed so striking is it, that many persons have considered it an invariable sign of disease of the heart. At any rate, when there is an obstruction to the course of the blood in the chest, we find a puffiness of the lower eye-lid.

*Palpitation, &c.*—Besides these, there are symptoms in the heart itself. There is palpitation, a great sense of fainting, and great difficulty of breathing,—particularly on motion. In this and all other diseases of the heart, the lungs are very much disposed to fall into a state of chronic bronchitis; so that the patient not only coughs but expectorates; and perhaps expectorates *blood*; and the difficulty of breathing becomes extreme. The quantity of urine is diminished; and then, frequently, a great accumulation of blood takes place in the liver, as well as in other parts; and at length there is effusion, not only into the pleura on each side, but into the peritonæum; so that perhaps, at last, we have not only œdema, but general dropsy.

*Preternatural Sounds Synchronous with the Pulse.*—There are two or three other points which it is desirable to notice, before leaving diseases of the lining membrane of the heart; and the peculiar and preternatural sounds, to which a narrowing of the different orifices gives rise. These preternatural sounds are heard far more frequently on the *left* side, than on the *right*; because (as I have repeatedly observed) *all* diseases of the heart are so much more common in that situation. In an infinitely greater number of instances, a preternatural sound is heard at the moment of the stroke of the heart, than either before or after it. At St. Thomas's Hospital, for months together, there has not been a single instance of a preternatural sound of the heart, except at the moment of the stroke of that organ;—so much less frequent is it to hear a preternatural sound at the time the auricles allow their blood to go into the ventricles. All cases of a bellows-sound, in which there was no real narrowing of the openings to be found after death, occurred at the time of the stroke of the heart; and where it has arisen from a temporary cause, and has gone off again, it has been at the same period; so that the impediment appears to have been at the mouth of the aorta. In the particular case which I mentioned,<sup>b</sup> where a woman had a bellows-sound as long as the abdomen was distended with liquid, and no longer,—for it ceased when she was tapped, and returned again when the water re-accumulated,—it was heard at the moment of the pulse. By far the most frequent seat of it, is the aperture leading from the left ventricle to the aorta.

*Usual Seat of the Sound.*—I need hardly say that, in general, the bellows-sound, when it arises from an obstruction of the mouth of the *ventricle*, is heard in the *lower* part of the cardiac region, in the situation of the ventricle; whereas, when it proceeds from a diminution of the opening of one of the *auricles*, it is heard at the *upper* part;—the auricle being situated above, and the ventricle below. We may sometimes hear the bellows-sound, not only in the situation where the obstruction exists, but to a great extent around. I have frequently heard it in the right axilla, when the heart was not at all enlarged; but frequently it is only perceptible at the place where the obstruction exists; and when heard in various parts,

<sup>a</sup> See Page 147.

<sup>b</sup> See Page 845.

it is always loudest in the immediate seat of its cause. Generally, therefore, it is loudest in the case of the *ventricles*, at the *lower* part of the cardiac region; and in the case of the *auricles*, or auriculo-ventricular openings, at the *upper* part. When it is on the *left* side, we hear it loudest in the *left* half; and when on the *right* side (where it is rare), we hear it loudest at the *right* part of the cardiac region.

[Within a few years much light has been thrown upon the subject of valvular murmurs, and the mode of their production.<sup>a</sup> It is now well established that murmurs seated in the semilunar valves are best heard immediately over those valves, that is, over the sternum and a little to the right of it, in the neighbourhood of the cartilage of the third rib. Murmurs seated in the auricular valves, on the other hand, are best heard near the apex of the heart, being most readily conducted to the surface, says Dr. Hope, through a solid medium, that of the *columnæ carneæ*.

T. S.]

*Double Bellows-Sound.*—Sometimes we hear a *double* bellows-sound;—one sound at the stroke of the heart, and then another immediately after it;—like something falling against some other object, and then falling back again directly. I believe that, in these cases, there is a degree of obstruction to the passage of the blood, which produces the *first* bellows-sound; and then, as the valves do not perform their duty perfectly, but permit a portion to reflux, we have the *second* bellows-sound. It is by no means a rare thing to hear this double sound; though it is not nearly so common as a single sound. When the mitral valve is grown up, so that we have merely a circular opening in the middle, of course there is great obstruction; and as the valve does not do its duty well, some of the blood always comes back, and a double bellows-sound is produced. So, in the case of the aortic valves, the opening is sometimes much diminished; and we have a bellows-sound when the blood rushes out; and, the semilunar valves being corrugated, a portion returns; and thus you have a see-sawing sound,—backwards and forwards.

*Sounds Influenced by the Heart's Action.*—I mentioned<sup>b</sup> that, in the case of the bellows-sound which occurs at the stroke of the heart, it is heard loudest when the patient lies down; and sometimes we can hear it only when the patient is in a horizontal position; but when he is standing up, it is always diminished. Variations takes place in this respect, however, according to the force of the heart. Sometimes the pulse is very irregular; so that first we have a strong thump, then a slight one, and then several strong ones. Now in these cases, if there be a diminution at the mouth of the aorta, when the heart acts moderately, it gives short strokes; so that the blood is not sent violently through the opening, and therefore it finds its way pretty well; but when it acts violently, such a torrent of blood is driven against the opening, that a great obstruction is felt; and then we have a loud bellows-sound. Thus, when there is a bellows-sound, and the heart acts irregularly, we sometimes hear it loud, and sometimes very inconsiderable; according to the quantity of blood driven against the opening, and the degree of obstruction experienced. If the parts be not very rigid, when the stroke of the heart impels the blood, it may force its way, and the obstruction will not be much felt; but if the parts will not give way, the greater the impulse, the more is the obstruction felt.

*Purring Thrill.*—Sometimes we perceive another circumstance when these bellows-sounds are present; and that is a vibration, like the purring of a cat. It is just the same gentle vibration, as that which is felt on placing our hand on a cat's back, when she is purring. This has been called "the purring thrill." I do not recollect noticing it in the case of the heart, except where there was a bellows-sound; and it appears to arise from an obstruction. It is nothing more than a jar given to the heart, by the blood attempting to pass through the obstructed opening. It is by no means generally observed; but, every now and then, we may feel a vibration in the region of the heart, at the moment the bellows-sound is heard.

*Variations in the Pulse.*—With regard to the heart's action, it varies both as to

<sup>a</sup> See Hope on Diseases of the Heart and Great Vessels, with Notes by C. W. Pennoek, M. D. Philadelphia, 1842.

<sup>b</sup> See Page 845.

force and frequency. It has been thought that this indicated the want of a free opening; but intermissions and irregularity of pulse (both as to force and frequency), will take place when there is no obstruction; and I do not know the particular state of the heart that gives rise to these variations. We may continually observe this occurrence, in old people, who never had disease of the heart. It is more frequently observed when there is an obstruction of the mitral valve; but it is by no means a necessary consequence of it.

When the auriculo-ventricular opening is narrowed, the pulse is generally irregular, both in force and frequency;—a peculiar combination well known to practitioners, in which several beats succeed each other in rapid succession and with tolerable force; while others again occur slowly, and with little force;—perhaps so weakly, that they can scarcely or not at all be perceived, although at the heart the pulsation is evident enough.<sup>a</sup> This most irregular pulse is thought by Mr. Adams<sup>b</sup> to be pathognomonic of narrowing of the left auriculo-ventricular opening. Corvisart thought extreme irregularity of pulse in both force and frequency to characterize narrowing of the aortic opening. I do not happen to recollect a pulse irregular in force and frequency, in a single case of narrowing of the aortic opening solely, while I know that it is very common in the narrowing of the left auriculo-ventricular opening; though possibly not peculiar to it, nor indeed to narrowing of any opening.<sup>c</sup> Mr. Hodgson also mentions, that in narrowing of the left auriculo-ventricular opening, there is often a double pulsation of the heart; that is, *two* beats of the heart to *one* of the wrist;—a pulsation of the heart from the action of the ventricle, and another from the action of the auricle. This able surgeon attempts to explain the fact; but expresses himself in rather an obscure manner. “The auricle,” he says, “first acts, and propels its contents into the ventricle; but (from the contraction of the communication) the blood is not, as in the natural state, poured at once into that cavity. The ventricle, though imperfectly filled, contracts, and forces the blood into the aorta. Thus there is a pulse caused by the action of the auricle, and another by that of the ventricle; so that, for every pulsation at the wrist, two are perceptible at the heart.” But the truth is that, even *in health*, there is perceptible to the ear a double action of the heart;—one of the auricles, and another of the ventricles; though this was not generally noticed at the time Mr. Hodgson wrote. When the left auriculo-ventricular opening is narrowed, —so that the blood can be only squirted into the ventricle,—this auricular action is sometimes very distinct to the hand, in the condition of a thrill or purring; which is what Mr. Hodgson had remarked, and called “an irregular thrill, or *bruissement*,” as Corvisart terms it, rather than a distinct pulsation.” Sometimes it is a distinct shock; and, in another sentence, Mr. Hodgson speaks of it as such:—“Thus there is a pulse caused by the action of the auricles, and another by that of the ventricles;” “nor is the auricular pulse trifling.”<sup>d</sup> This happens only, I believe, when the walls of an auricle are increased in substance,—hypertrophied; so that they act with a force approaching to that of the ventricles, and a double stroke of the heart may be felt by the hand. That this, and not the imperfect repletion of the left ventricle (by which it acts twice), is the reason of the double stroke, appears to me shown by the fact that, when it has been observed, the auricle or auricles have always been hypertrophied, and in some cases the auriculo-ventricular opening not at all narrowed; and, secondly, that it is not observed, however narrow the auriculo-

<sup>a</sup> In cases of any disease, if the pulse is too rapid to be counted at the wrist, it may almost always be counted at the heart. I have easily counted two hundred pulsations at the heart, when it was impossible to count the pulse at the wrist. Ossification of the radial arteries causes the pulse to be feeble, while perhaps the action of the heart is natural, or even very strong; and in cases of this condition of the vessels, and in many others, the action of the heart should always be examined at the chest.

<sup>b</sup> “Dublin Hospital Reports,” Volume 4; Page 424.

<sup>c</sup> Laennec considers irregularity in frequency to arise generally from dilatation; and this is a common consequence of narrowing of an opening.—See *Dr. Forbes's Translation*, Part 2; Book 1; Chapter 7; Paragraph 1. (Third Edition; Page 579.)

<sup>d</sup> “A Treatise on the Diseases of Arteries and Veins.” Dr. Parry, in his work upon the pulse, adopts, without reference, Mr. Hodgson's explanation.

ventricular opening, if the auricle is not hypertrophied. This hypertrophy is rare; as the obstruction usually produces dilatation and thinning.<sup>a</sup>

Corvisart remarks that obstruction at either aperture on the left side, causes more irregularity than obstruction on the right. Even the thrill is frequently absent when the narrowing is considerable, and I am ignorant upon what exact conditions it depends;—whether upon the degree of the narrowing, or the shape of the diseased opening, or some other cause.

A third peculiarity has been remarked in the narrowing of the left auriculo-ventricular opening; namely, smallness of the pulse; and a good example of this is given by M. Abernethy,<sup>b</sup> and another by Mr. Adams.<sup>c</sup> The small quantity of blood poured into the left ventricle, at each auricular contraction, is insufficient to enable this cavity to project a due portion into the arteries;—whence the smallness of the pulse. But the same smallness of pulse results from a narrowing of the aortic opening; and nothing but the observation whether the preternatural sound which may exist occurs at the auricular or ventricular action, can determine whether the narrowing is at the auriculo-ventricular, or at the ventriculo-aortic opening. It may also result from a general diminution of the cavity of the left ventricle, accompanied by no narrowness of opening; for this, equally with a diminution of aperture, must obviously occasion a small projection of blood into the arteries. The importance of this symptom alone, therefore, is absolutely nothing. It does not necessarily indicate narrowing of the openings in the left side of the heart. If, indeed, the preternatural sound is heard at the ventricular contraction, this smallness of pulse may assist in leading to the idea, that the narrowing is on the left side of the heart; but the greater loudness of the sound on the left side, will sufficiently declare it. The inferiority of this symptom in the pulse to the observation of the preternatural sound, is shown by the preternatural sound occurring long before the pulse grows small. I have often noticed no smallness of pulse up to the time of death, in cases where an auricular or ventricular preternatural sound, loudest on the left half of the cardiac region, showed the left auriculo-ventricular or ventriculo-aortic opening to be diminished; and, after death, this state of parts was discovered.

When the narrowness is at the mouth of the aorta, the action of the left ventricle,—notwithstanding that the pulse is small,—is sometimes very strong; owing to its walls being hypertrophied.

*Necessity of observing all the Symptoms.*—There are no symptoms, except those learned by the ear, to indicate particularly what is the seat of the obstruction; or, indeed, whether there is any obstruction at all; but we shall be much deceived, unless every thing be taken into consideration. If we hear a bellows-sound, it is not right to infer that there is structural disease of the heart. In order to justify our coming to that conclusion, the sound ought to be heard *constantly*,—not to-day only, but to-morrow and every day; and even then we ought not to be satisfied, unless we find other symptoms;—such as enlargement of the heart, dulness of sound to a great extent, anasarca, great distension of the veins, and so on. The whole circumstances of the case must be taken into consideration. Useful and important as it is to attend to the sounds addressed to the ear, it is absurd to depend

<sup>a</sup> See the "Dublin Hospital Reports;" Volume 4; Page 416.

<sup>b</sup> "Medico-Chirurgical Transactions;" Volume 1; Page 27.

<sup>c</sup> Mr. Adams ("Dublin Hospital Reports," Volume 4, Page 435) refers the double pulse to hypertrophy and dilatation of the right ventricle, which acts strongly; while the left has too little blood to discharge into the arteries, to give a pulse regularly. But, as the left ventricle acts and empties itself every time the right ventricle does so, there is no reason why it should not accumulate blood enough to occasion a perceptible pulse. Disproportionate pulsation of the heart and of the arteries is, of course, owing to a strong pulsation of the right ventricle, and often also of the left,—both or either of which are often hypertrophied,—and the small quantity of blood discharged from the left. A regularly double pulsation at the heart appears very explicable, in the mode mentioned in the text. When the pulse varies in force at different moments, I have always observed the strokes of the heart to vary proportionally.

upon any one of these, to the neglect of all the general symptoms, which medical men notice in the ordinary way.

*Effects upon the Lungs.*—It has been thought that when there is an obstruction on the *right* side of the heart, the jugular veins are more distended, and the obstruction in the venous system more evidently shown, than when it comes on the *left*. This is no doubt a fact, up to a certain point; but it is to be remembered, that an obstruction on the *left* side of the heart must produce the same effects, after a time. There will at last be great congestion in the lungs; and, in consequence of that, there must be an obstruction to the blood passing on the *right* side of the heart; then there must be a distension of all the veins, and dropsy. We cannot depend upon these symptoms alone. When the veins of the neck are distended, that circumstance, considered in itself, will not justify us in saying that the obstruction is seated on the *right* side of the heart. It *may* arise from an obstruction there; but there may be a real organic obstruction on the *left* side. There is, however, this difference:—when the obstruction occurs on the *right* side, there is far less difficulty of breathing than when it takes place on the *left*. The blood is not at all impeded in its progress through the lungs; the obstruction exists before it goes there; but when the obstruction is on the *left* side, it causes great dyspnoea, on account of its producing congestion of the lungs. But greater reliance cannot be placed on this point; for this reason:—in structural disease of the heart, the lungs are much disposed to become diseased too. From their contiguity to the morbidly affected heart, they are much disposed to fall into chronic bronchitis; and when that occurs, we have all the signs of difficulty of breathing, and of congestion of the blood. Still it stands to reason, that if there happen to be no chronic bronchitis,—no affection of the lungs, there will not be dyspnoea when there is an obstruction only on the *right* side of the heart; whereas, if the obstruction be on the *left* side, we must expect it.

---

## CHAPTER III.

### DISEASE OF THE SUBSTANCE OF THE HEART.

I WILL now proceed to the consideration of diseases of the *substance* of the heart; and I think this arrangement will make the matter plain. First we considered the membrane *investing* the heart; then the membrane *lining* the heart; and now we will consider diseases of the *muscular substance* of the heart.

#### SECTION I.—CARDITIS.

The substance of the heart is now and then, but very rarely, the subject of acute inflammation. I do not myself recollect having seen an instance of it; but a most decided case is recorded by Mr. Stanley, in the seventh volume of the “*Medico-Chirurgical Transactions*.”<sup>a</sup> The symptoms of this disease, would be very similar to those of pericarditis. In the case mentioned by Mr. Stanley, there was pericarditis likewise present.<sup>b</sup> I hardly think it can exist without that affection being conjoined with it. Extreme faintness has been observed. There is sometimes extreme faintness in *pericarditis*; but it is not common. In the case of inflammation of the substance of the heart, however, extreme faintness has been noticed;—fits of syncope, indeed. After death, in these cases, the substance of the heart has

<sup>a</sup> Page 323.

<sup>b</sup> “*Medico-Chirurgical Transactions*,” Volume 7; Page 326.

been found soft, and black with congestion. The accumulation is so great, that the substance of the heart is black. In Mr. Stanley's case, the disease had proceeded even to suppuration; so that there were little collections of pus, with which the heart was studded.

## SECTION II.—HYPERTROPHY AND DILATATION.

With the anatomical marks of previous pericarditis, or inflammatory change of the lining membrane of the heart, or after pain in the cardiac region and palpitation, perhaps occurring during or subsequently to rheumatism, we frequently observe the heart thickened or dilated, or both.<sup>a</sup>

*The Result of Inflammation.*—I am convinced,—with Bouillaud, Bertin, Andral, and others,—that the increase of the heart's substance, no less than the diseases of the valves, is generally inflammatory. I have witnessed, after acute rheumatism, a constant and severe pain in the region of the heart, palpitation, and at length death; and found the left ventricle thickened, without any other morbid appearance in the organ; and here, no less than when the ordinary anatomical results of inflammation were visible, it was impossible not to consider the change inflammatory. On comparing an hypertrophied left ventricle with a healthy specimen, M. Chevalier (a pupil of Vauquelin's) found, under the microscope, that its fibres were redder; and, a portion of each being steeped in a separate quantity of distilled water, the hypertrophied portion reddened the water more than the other, and when taken out was still the redder of the two. On being put into boiling alcohol, it proved to contain less fatty matter.<sup>b</sup> Indeed an hypertrophied heart, if undilated, is always in the affected portions redder and firmer than usual; and its coronary arteries are enlarged, sometimes enormously. Besides, as hypertrophy is a common accompaniment of chronic inflammation of the outer or inner membrane of the heart, no doubt can exist upon the subject. Indeed its essence, being excessive nutritive action, cannot but be in some measure inflammatory. It is unquestionably produced, in some cases, by obstruction in the opening leading from the cavity whose walls are thickened;—the difficulty giving rise to evident great muscular effects, and consequently to augmented circulation, of the organ. But even here it may be to some degree inflammatory; because the lining membrane of the cavity has generally been in an inflamed state; which, in truth, was the cause of the valvular obstruction.

*Varieties of Hypertrophy.*—Hypertrophy of the left ventricle is often found with disease of the lining membrane of the aorta; sometimes coexistent with true or false aneurism of the aorta; but not unfrequently the sole diseased appearance. Hypertrophy is frequently attended with dilatation; and more so, perhaps, when there exists an obstruction to the egress of the blood from the diseased compartment. Dilatation often occurs alone, especially in the auricles, from this cause. But, like hypertrophy, it is sometimes the only morbid circumstance discernible; and therefore not so easily to be explained. The dilated portion, we shall find, is occasionally thin and soft; and the reason of the dilatation is then evident.

Hypertrophy is considered by Bertin, according as the compartment of the heart is simply thickened, without any change in the dimensions of the cavity: as it retains its natural thickness, but is dilated; in which case there must be an hypertrophy or preternatural quantity of substance, or it would have become thinner: and, thirdly, as it is not merely thickened, but its cavity diminished. He designates

<sup>a</sup> It is in general said that the heart is naturally about the size of the fist of the individual: that the walls of the left ventricle are twice as thick as those of the right, and in infancy and old age four times as thick; but that the "columnæ carnae" of the left are less voluminous than those of the right, though the surface of the left presents a more delicate and intricate reticulation: that when the two ventricles are cut into, the left should remain open, but the right fall together: and that the capacity of the two ventricles is equal.

<sup>b</sup> Bertin.

these three forms "*simple* hypertrophy," "*eccentric* hypertrophy," and "*concentric* hypertrophy."

The second variety, "*eccentric* hypertrophy,"—or increase of substance and dilatation united,—was described by Senac, Morgagni, and Lancisi; and was denominated, by Corvisart, "active aneurism of the heart." It is the most common of the three; and the excessive deposition must have taken place in the direction of the surface. The first variety, "*simple* hypertrophy," in which the dimensions of the cavity are unchanged, and the deposition takes place also in the direction of the surface; and the third, the "*concentric*," in which the cavity is diminished, and the deposition must have occurred in a vertical direction,—at a right angle with the surface, were first described in 1811, by Bertin.<sup>a</sup> In the "*concentric*," the cavity is sometimes so small that it will scarcely contain the shell of an almond.

Every heart with thick parietes and a small cavity, however, is not perhaps an example of "*concentric* hypertrophy." A violent contraction at death might probably produce these effects. But, in such a case, the bulk of the organ would be proportionately lessened. To be justified, therefore, in declaring the existence of "*concentric* hypertrophy," not only the parietes should be thick and the cavity small, but the bulk natural.

In the "*simple*" and "*concentric*" hypertrophy of the left ventricle, the thickness is sometimes double, or even triple, what is natural; the walls of the left ventricle, in the healthy state, are about half an inch thick. In the first and second varieties ("*simple*" and "*eccentric*"), the thickening of the left ventricle is generally greatest at the base, and lessens towards the apex. In the "*concentric*," there is usually as much thickening at the apex as at the base. The septum of the ventricles, and even the "*columnæ carneæ*," participate in the increase of substance. The thickening is sometimes unequal in different parts;—both in the case of the left ventricle, and of any other part that may be hypertrophied. The right ventricle, when not participating in the disease, is comparatively so small, and reaches so short a way down, that it looks like a mere appendage, or as if included in the walls of the heart.

*Most Common in the Left Ventricle.*—The left ventricle is the most usual seat of hypertrophy. When the disease occurs in the right, the thickening is seldom (if ever) so great, and is generally more uniform; but the "*columnæ carneæ*," it is said, are generally more enlarged in proportion. Sometimes both ventricles are hypertrophied; sometimes one is hypertrophied, in one or other of three varieties of the affection ("*simple*," "*eccentric*," and "*concentric*"), while its fellow is only dilated.

*Rare in the Auricles.*—Hypertrophy rarely affects the auricles; and still more rarely unless other disease exists in the heart. It is generally united with dilatation of the auricle. Laennec,<sup>b</sup> and many others, never witnessed an instance of pure hypertrophy of an auricle.<sup>c</sup>

If the walls of all the cavities of the heart, or even both ventricles only, are affected with hypertrophy and dilatation, the heart may acquire an enormous size. In these circumstances, its form usually becomes rounded,—its apex being effaced; and it lies almost transversely in the chest. The thickening is in the walls of a cavity; sometimes partial only; and even thickening and dilatation may exist separately, in different parts of the walls of the same cavity. The "*columnæ carneæ*" are in some instances more thickened, in others less, as compared with the walls.

<sup>a</sup> See "Traité des Maladies du Cœur, et des Gros Vaisseaux; par R. Bertin. Rédigé par J. Bouillaud." ("Treatise on the Diseases of the Heart, and Great Vessels; by R. J. Bertin. Edited by J. Bouillaud.") Book 2; Section 2; Chapter 1; Article 2; Subdivision 1. (Page 432 of the Paris Edition of 1824.)

<sup>b</sup> See his Treatise on Diseases of the Chest; translated by Dr. Forbes. Part 2; Book 2; Chapter 6; Paragraph 2. (Third Edition; Page 614.)

<sup>c</sup> We have observed hypertrophy of the auricles under the triple form described as affecting the ventricles ["*simple*," "*eccentric*," and "*concentric*"]; but hypertrophy with dilatation ["*eccentric* hypertrophy"] is incomparably more frequent than the other two.—Bertin's "*Treatise on Diseases of the Heart*." Book 2; Section 2; Chapter 1; Article 1; Subdivision 3. (Pages 335 and 336 of the Paris Edition of 1824.)

*Varieties of Dilatation.*—In *dilatation* of the heart, as we have seen,<sup>a</sup> the natural thickness of the dilated parietes may be retained, or their thickness may be augmented: but there is a third variety of dilatation—the thickness may be diminished; and this was denominated “passive aneurism.” The first of these varieties—that in which the dilated parietes retain their natural thickness—appears to me, I confess, as true an hypertrophy as the second,—in which the thickness is increased; because dilatation would inevitably occasion attenuation, were not an addition of substance made. Two or even three of these varieties may exist in the parietes of the same cavity.

*Causes of Dilatation.*—Laennec regards original disproportion of the cavities, as the most powerful cause of dilatation.<sup>b</sup> But, certainly, a very common cause is obstruction to the progress of the blood from the cavity; and the source of this obstruction may be situated in another cavity;—in one farther forwards, relatively to the blood’s course. It is frequently the auricle, and not the ventricle, that is dilated, when there is an impediment at the opening of the aortic or pulmonary artery; and when the difficulty is at the aortic opening, it is sometimes not the left auricle, but the right, which becomes dilated. The obstacle may arise from a diminution of an opening, or from diminution of another cavity; as of the left ventricle. A permanent patency of the auriculo-ventricular opening, by which too much blood attempts to rush into the auricle, will create marked dilatation of it.

The auricles, from their thinness, are more subject to dilatation than the ventricles; and the right than the left,—from the frequency of obstruction in the lungs: but both ventricles are often dilated simultaneously. Dilatation would appear sometimes to be of only temporary duration; and the right auricle often becomes dilated in the dying state, especially when this state is lingering, from the impediment to the blood’s passage through the lungs.

While, in pure hypertrophy, the substance of the affected portion is usually very firm and red, it is usually soft and pale in dilatation with thinness: and when hypertrophy and dilatation exist together, the substance is generally firm or soft, accordingly as the hypertrophy or the dilatation is the greater. In dilatation of the ventricles, the septum suffers least; and, contrarily to what happens in hypertrophy, the expansion takes place chiefly in the direction of the breadth;—so that when both ventricles are dilated, the heart becomes usually almost round.

Dilatation occurs oftener in women than in men;—probably, as is supposed, from the female heart being naturally thinner. Hypertrophy and dilatation frequently co-exist in the walls of different cavities of the same heart.

*Signs of Hypertrophy and Dilatation.*—Let us now inquire into the signs of hypertrophy and dilatation. When the heart is hypertrophied, an unusually strong impulse is given in the situation of the part affected, and the sound usually heard there is diminished,—becomes a sort of murmur; and in severe cases it is not heard at all. The contraction takes place more slowly than in the healthy state; and, in the hypertrophy of the ventricles, little or no interval of repose occurs after the auricular action. When the heart is dilated, the reverse happens;—there is far less than the usual impulse in the situation of the part affected; and the sound usually heard there is augmented, and is not merely louder, but clearer than natural. In dilatation of the ventricles, their action takes place more rapidly than in the healthy state; and, as in hypertrophy, little or no interval of repose occurs.

In hypertrophy of the left ventricle,—its most common seat, a strong impulse is felt between the cartilages of the fifth and sixth left ribs; and the action of the auricles is very short. In hypertrophy of the right ventricle, this strong impulse is felt at the lower part of the sternum.

If the difference is considerable, it is easily discovered by the greater force with which the stethoscope is repelled in the affected side, when applied to the auricles and the sternum in succession. Where the difference is less, it may perhaps

<sup>a</sup> See Page 852.

<sup>b</sup> See Dr. Forbes’s Translation of Laennec’s Treatise. Part 2; Book 2; Chapter 3; Section 1; Paragraph 2. (Third Edition; Page 604.)

be more easily ascertained, by examining both sides at once;—placing the hand longitudinally over the cardiac region; when the stronger impulse against the fingers lying over the left or the right half of the region, will presently be noticed. In health, the impulse in both halves is equal. Should hypertrophy affect both ventricles at once, the excess of impulse in both halves will determine its existence in both; and the equality or difference of the morbid impulse, will demonstrate its equality or difference in the two ventricles.

Hypertrophy of the auricles must be very considerable to afford an impulse; which, when present, will be felt in the *right* or *left* superior half of the cardiac region,—according to the situation of the hypertrophy. The situation of the loud and clear sound of dilatation, equally agrees with the seat of the dilatation.

The accuracy with which the seat and nature of these diseases can be determined, is wonderful. If due attention be given, and the symptoms carefully investigated, a physician may pronounce with certainty, frequently even at the first visit, that a particular ventricle or both are hypertrophied or dilated, or the two in opposite states;—no less than that an opening in a particular cavity is deranged; and an examination after death will verify his assertions. Laennec considers these results of auscultation, when well marked, infallible; and so I believe them to be. A good auscultator, after making a full investigation, will never object to write down his opinion, and deliver it to another, for the purpose of being read at the autopsy.

When hypertrophy and dilatation coexist in the walls of a cavity, the two sets of auscultatory signs are blended; and those of hypertrophy or of dilatation predominate, accordingly as either state predominates. In general, the hypertrophy exceeds the dilatation; for, not only do we continually see an increase of thickness with dilatation, but, however extensive the dilatation, if the natural thickness be undiminished,—nay, even if it be diminished, but not in proportion to the dilatation,—hypertrophy must still exist. In these compound cases, therefore, the sign of hypertrophy,—the preternatural impulse,—is generally the more prominent phenomenon; and I own myself to have repeatedly pronounced a case to be one of hypertrophy, when the cavity was likewise to a certain degree dilated;—the dilatation, however, being much inferior to the hypertrophy; and the injury to the system arising, not from the dilatation, but from the hypertrophy. This combination is every day seen in the left ventricle, the great disease of which is hypertrophy; but, with its hypertrophy, there is generally more or less dilatation.

When the left ventricle is severely affected in this twofold manner, its violent pulsations are felt, not merely in the left lower half of the cardiac region, but also under the sternum, and even to the right of this bone: for the growth of the diseased ventricle pushes the right outwards and backwards, and occupies its place as well as the left side. But there is violent impulse, equally, in the left half of the cardiac region;—proving the hypertrophy of the left ventricle; and there is a dull sound on striking the sternum;—from the presence there of the enlarged left ventricle.

The cardiac region of the front of the chest corresponds with the lower third or the sternum: and thus the cartilages of the fourth, fifth, sixth, and seventh ribs, have a *right* and a *left* half. The *right* or *sternal* half, sounds clear on percussion in the healthy state, and often even under dilatation of the right cavities: but enlargement of the heart from hypertrophy and dilatation, or the deposition of solid or fluid upon or around the organ, makes it sound dull or dead. The *left* or *costal* half of the cardiac region naturally sounds rather dull in most persons; and even dead in fat, anasarcaous, and muscular persons; except at the highest (the auricular) part, where some hollowness of sound is almost always heard, unless in enormous dilatation of the auricles;—such as exists only with constriction, Laennec says, of the left auriculo-ventricular opening.

*Dead Sound on Percussion.*—A considerable dilatation of the heart necessarily causes a dead sound to be heard more extensively than usual, on striking the cardiac region with the ends of the fingers; and M. Piorry assures us, that if a hard elastic substance is interposed at the time between the chest and the fingers, such a

distinctness of sound is produced, that the size of the portions of the heart immediately under the sternum and ribs may be ascertained, with the greatest nicety.<sup>a</sup> The auscultatory signs are the only means of accurately ascertaining the existence and seat of these affections.

*Palpitation.*—It is in some of these instances of combination of the two affections in the left ventricle, that we frequently see those dreadful cases of violent palpitation, and of throbbings of the arteries: and for no other reason, I presume, than that hypertrophy is here carried to the highest pitch; for when, notwithstanding extensive dilatation, the walls are thickened, the quantity of additional substance must be enormous. Towards the close of even this variety of hypertrophy, the impulse is often much reduced, and the heart sometimes grows soft;—so that the pulse is weak, and the morbid action of the heart is recognized only in the cardiac region. The occurrence of pneumonia may also obscure the stethoscopic signs while it lasts.

The pulse, the respiration, the state of the veins, the secretion of the cellular and serous membranes, the countenance, the state of mind, may all suffer; but the changes induced are too varied for any reliance; and may owe their origin to many other circumstances.

*State of the Pulse.*—In hypertrophy, especially with dilatation, the pulse is frequently full;—causing headache, and even apoplexy, if the vessels of the brain are weak or diseased: but when the opening of the mitral or aortic valves is narrowed, the pulse may be very small; while the left ventricle is hypertrophied, and beats violently. In mere hypertrophy, the pulse is small, if the variety is the “concentric;”—where the addition of thickness is attended by diminution of cavity. Irregularity of pulse is natural to some persons; so that regularity occurs only in disease. In others irregularity depends upon disease of the head, stomach, intestines, or lungs. Frequent faintness may be a purely nervous or sympathetic affection. Violence of arterial pulse may be purely functional; and, although the action of the heart be also violent, particularly on lying down, we generally determine with ease that the violence is independent of hypertrophy: but only by noticing that the violence is general,—is of both ventricles and both auricles; whereas in hypertrophy, it is nearly always confined to, or is much greater in, one cavity of the heart than another; the rhythm is altered; and often some sound preternatural in quality or morbidly intense, is constantly heard in some one cavity;—indicating organic disease.

*Anasarca, &c.*—It might be suggested that, in many cases, the presence of anasarca, lividity, and tumefaction of the countenance, would assist us in discriminating organic disease. But palpitation may be violent, and these symptoms present, without organic affection of the heart:—a chronic bronchitis, or an original dropsy of the pleura may exist, and produce these symptoms; and here, nothing but auscultation can determine whether the heart is sound, and the anasarca referable merely to the lungs or pleura. In all three cases, the anasarca usually commences in the feet.

*Remission of the Symptoms.*—Again: the symptoms produced by a diseased heart will sometimes so remit,—either from a decline of the ordinary irritation of the heart, or the cessation of some temporary irritation of another organ,—as to create a doubt in the mind of any but an auscultator, that organic disease of the heart had really existed. Even the dropsy, frequently attendant upon organic disease of the heart, subsides and returns, without evident reason; or accordingly as the patient is quiet in body and mind, and careful with respect to diet and vicissitudes of temperature, or the reverse.

*Duration.*—Frequently, too, auscultation will disclose cardiac disease, and the symptoms may not increase for many years;—so that the auscultator may be ridiculed, and no organic affection be admitted; when, from unfavourable circumstances

<sup>a</sup> “C’est à une ligne près que cette mensuration est précise.” (“The size may be determined almost to a line.”)—“Journal Hebdomadaire,” No. 30, Page 137. See also his work on the same subject, published in 1828.

or the progress of life, the disease may suddenly begin to augment, and dissection disclose some organic affection. Many persons die of organic cardiac disease after forty; though, for many years of their lives, they had merely a little dyspnœa, with occasional palpitation, and swelling of the feet; and were told that they were free from all disease of the heart. Indeed, Laennec was convinced, that congenital disproportion of the cavities of the organ, was one of the great predisposing causes of its dilatation.\* In slight cases of the "blue disease," where a small direct communication existed between the right and left sides of the heart, I have seen the symptoms—after being stationary during the whole of infancy, adolescence, and the earlier part of manhood—at once augment;—from the sudden enlargement, I presume, of the preternatural opening; either through the enlargement of one of the cavities between which it formed a communication, or the occurrence of narrowness of one of the natural openings of the heart farther on.

The general symptoms, however, may each be highly useful, when viewed by the side of the symptoms discovered by auscultation: they may confirm the diagnosis; or, rather, they may unite with the last mentioned symptoms, in forming a satisfactory theory of the nature of the case. They should never be neglected; for all the phenomena of every disease deserve the attention of a good practitioner.

*Treatment of Hypertrophy.*—I have no doubt that hypertrophy of the heart may sometimes be cured. The heart (as I mentioned before<sup>b</sup>) is evidently in an inflammatory state. The organ, for the most part, toward the close of the disease, is not only firmer and harder than it should be, but likewise redder; and frequently there is pain in the region of the heart, and even pericarditis also. Now, if we make a person live on low diet, cup repeatedly over the heart, keep him perfectly still, and relieve the bowels when it appears requisite,—so that there shall be no congestion anywhere; and if we exhibit colchicum, perhaps digitalis, and sometimes mercury, if he can bear it;—the symptoms of hypertrophy will gradually decline. I have certainly known several cases,—where I had every reason to believe that the hypertrophy was very great,—in which abstinence from meat, spirits, and things of that description,—abstinence from mental excitement,—abstinence from every occupation of mind which could cause anxiety,—abstinence from exercise, and every circumstance that could quicken the pulse,—was followed by a decline of the symptoms; and the patient became comparatively well. This however, requires a long time; and after the patient appears quite well, he must persevere in the general plan, though it need not be very assiduously carried on.

*Advantage of Local Bleeding.*—Local bleeding, for the most part, answers better than general bleeding. It is not very safe, in chronic diseases of the heart, to bleed at the arm; for, now and then, patients will fall into a state of syncope; and it is a dangerous thing, in diseases of the heart, to bleed to syncope. We have all heard of cases, where a patient with diseased heart has lost more blood than was intended; so that faintness was produced by the abstraction even of a couple of ounces, and the individual has died. A remarkable instance of this kind happened within the last few years. A distinguished personage,<sup>c</sup> labouring under disease of the heart, was bled at the arm. The bandage slipped; and although (it is said) only a few ounces escaped, yet he fainted and died. It is more safe, therefore, to take blood from the region of the heart itself, by means of cupping or repeated leeches, than to bleed at the arm; for it is dangerous to induce syncope. If we do bleed generally,—as we often may, with perfect safety, when the patient is strong and hearty,—it should not be to the extent of syncope; because patients with diseased heart will sometimes die suddenly. Indeed, it is not an uncommon occurrence; and they die, more frequently than not, through syncope.

*Treatment of Dilatation.*—Active measures are not required in such a case as this. We have merely to bleed locally (in order to take off the congestion), to keep an open state of the bowels, and to enjoin rest. Very frequently, however,

\* See Laennec's "Treatise on Diseases of the Chest," translated by Dr. Forbes. Part 2; Book 2; Chapter 3; Section 1; Paragraph 2. (Third Edition; Page 604.)

<sup>b</sup> See Pages 851 and 852.

<sup>c</sup> Sir Thomas Lawrence.

tonics are required. If the pulse is soft and feeble it would be dangerous to take away blood;—the only object of venesection being to remove congestion. Leeches, applied to the anus, frequently answer a good purpose in such cases; but, for the most part, a strong evacuation is not at all required. When, however, there is dilatation, there is (much more frequently than not) hypertrophy, and a disposition to dropsy. From the dilatation, the blood is not sent out so freely as it ought to be; and, consequently, there is an accumulation, and a tendency to morbid secretion in the cellular membrane; and in the serous cavities. Great congestion takes place in the liver, and likewise in the head; and there is also a tendency to general effusion. Such being the case, it is very desirable to give diuretics; and a combination of three or four, as I formerly mentioned,<sup>a</sup> is best. Squills, digitalis, and acetate of potash, answer very well. In fact, I do not know any thing so good. They answer far better than hydragogue purgatives. Patients are very much relieved by measures of that description; but if they be weak, we shall find it serviceable to give iron; and I believe the best preparation is the Ferri Potassio-Tartras; because, in conjunction with other means, it has a tendency to increase the flow of urine, and the discharge from the bowels. I have seen patients with every symptom of dilatation of the heart, lose the greater part of these symptoms, and be able to go about, after taking the potassio-tartrate of iron. As I formerly mentioned, it may be given in large doses. In fact, instead of a few grains, we may give a drachm, or even two drachms, twice or thrice a day; but still we cannot give it in such large quantities as the sesquioxide;<sup>b</sup> because it is apt to purge and to pinch. Many persons cannot take more than a drachm. When it is mixed with treacle, it opens the bowels, causes an increased flow of urine, and strengthens the patient. If it should purge too much, it is a good plan to mix with it an equal part of the sesquioxide.

*Superiority of Iron.*—In such cases, I should give this tonic in preference to all others; because I know, from experience, that it answers so much better than they do. Many cases of hypertrophy with dilatation occur, where the patients are in a state of anæmia,—in a leucophlegmatic condition; and if we take blood away, it is watery, and we make the patient worse. When patients are in a state of anæmia induced by blood-letting, or in that peculiar state in which the blood is not properly manufactured, the pulse will become sharp; and so, in disease of the heart, we sometimes have a sharp pulse, with great debility of the patient. Whenever I have seen this condition united with disease of the heart, I have abstained from evacuations, and given preparations of iron; and have found the patients improve. But if there is a tendency to effusion,—as shown in the ankles, or if we hear mucous or other rattles in the bronchia, diuretics are of essential service. If there be general paleness and debility, then iron is one of the best things that can be given; and if the debility be very great, while we give diuretics, we should exhibit the potassio-tartrate of iron; which is both a diuretic and a tonic. With such treatment as this, it is wonderful how much good may be done. We may certainly cure some cases; and even where the affection is very severe,—so that a cure is out of the question,—we may still do a certain portion of good;—we may make the patient feel better than before, and may prolong life. It is our business to protract life, whether it be desirable for the patient or not. It is our business to act upon a general rule, and endeavour to prolong life; without considering, for a moment, whether the individual would be better *out* of the world than *in* it. If we treat all these cases antiphlogistically, we may do harm. When there is a state of anæmia, the adoption of such measures would be madness. The administration of iron, and even good nourishment, is then the proper treatment.

### SECTION III.—ANEURISM OF THE HEART.

*Partial Dilatation.*—Dilatation of the heart is sometimes partial. Dr. Bertin

<sup>a</sup> See Pages 172 and 745.

<sup>b</sup> See Page 656.

says, that he has frequently found a cavity dilated in one point; while in every other it preserved its natural state, or was even narrowed or hypertrophied.<sup>a</sup> "The right ventricle, for example," he adds, "is often considerably dilated near the pulmonary artery; while the rest of the chamber preserves its ordinary dimensions." I have not yet met with this; but now have before me an example of partial aneurism of the heart;—of aneurism such as occurs in arteries, and therefore necessarily partial.

*Cases on Record.*—Upon the superior and lateral part of the heart of a young negro who had died in a state of asphyxia, Corvisart found a tumour nearly as large as the heart itself. Its interior contained several dense layers of coagula, perfectly similar to those which fill the cavities of arterial aneurism; and communicated with the cavity of the ventricle by a narrow opening, the margin of which was smooth and polished. The German anatomist, Walter the elder, had previously described a case of this kind. Drs. Baillie,<sup>b</sup> Zannini, James Johnson, Cruveilhier, Rostan, Breschet, each mention one; Dr. Berard mentioned two; and Talma's heart proved to be in this state.<sup>c</sup> Two aneurisms are mentioned by Dr. Reynaud, as occurring in the same heart.<sup>d</sup> There are two specimens in the museum of St. Thomas's Hospital: in one the aneurism is nearly as large as the heart; and in the other the aneurism is pyramidal, and projects into the left auricle. One lately occurred at St. George's Hospital; and, like one of those at St. Thomas's, projected into the left auricle.<sup>e</sup> Two are mentioned by Mr. Adams; one of which was, like the other at St. Thomas's, nearly as large as the heart.<sup>f</sup>

*Situation at which it occurs.*—In all these cases, the aneurism existed in the left ventricle: in some, at the apex; in others, almost equally numerous, at the base;—as in the case before me, in which there are two aneurisms; in others, between the base and apex;—in Corvisart's at the side, in others at the front. Aneurism is a disease of arteries, never of veins; and it is remarkable, that the disease was never detected but in the left (the arterial) side of the heart; and, indeed, never but in the ventricle, with which the general arterial system is directly continuous. This circumstance accords both with the general observation of the greater frequency of all diseases on the left than the right side of the organ, and in the ventricle than the auricle; and with the other fact, that this individual disease (aneurism) is arterial; or rather, I would say, is a disease of parts containing decarbonized blood; for the pulmonary artery, containing black blood, has not (I believe) yet been seen the seat of aneurism.

*Most frequent in Men.*—As far as appears known, all the instances, but one, have occurred in adult males; and *arterial* aneurism occurs eight times more frequently in males than in females.

*Symptoms not known.*—This cardiac affection is the first of those in which auscultation renders no assistance. All the cardiac diseases in which it is useful, have been considered. The general symptoms which occur may well, therefore, be supposed, by those who know the value of auscultation, to leave the nature of the disease in doubt. Dr. Baillie says the symptoms "are similar to those which belong to aneurism of the arch of the aorta." And what does Dr. Baillie enumerate as the symptoms of aneurism of the arch of the aorta? First, difficulty of breathing. But that may arise from many other causes in the heart, lungs, or other parts; and has been absent in this disease. Secondly, more or less of pain in the aneurismal tumour, or some other part of the chest. But here is no tumour; and pain in some other part of the chest would certainly never lead us to a knowledge of the disease, but rather to a misconception of its seat and nature. The pulse, he says, is sometimes irregular; but immediately subjoins, that "often no irregu-

<sup>f</sup> "Dublin Hospital Reports;" Volume 4.

larity can be felt in it." The chief symptoms he pronounces to be "a strong pulsation in the chest, commonly visible to the eye, when the chest is exposed to view." But again immediately subjoins, that he has felt the same kind of pulsation in other cases: for example, in adhesion of the pericardium, slight pericarditis with slight hydro-pericardium, and in ordinary morbid enlargement of the heart. Indeed, no strong pulsation, except palpitation of the heart, and in most cases not even that, has occurred in this affection. The most decided characteristic of the disease, however,—belonging only to aneurism,—he regards as a strong pulsating external tumour, when the aneurism has attained a large size. But aneurism of the heart rarely attains a large size; and I do not know that it ever produced an external tumour. And after all, a diagnosis would be required between aneurism of the heart and of the arch of the aorta. It therefore appears to me,—and I say it with all the respect due to an amiable and industrious man,—that Dr. Baillie would have done better in saying, that there were no particular symptoms of the disease; especially as he never met with more than one example of it.<sup>a</sup>

In Talma, who died of strangely neglected stricture of the rectum, no symptoms had led to a suspicion of cardiac disease.<sup>b</sup> In a patient of Dr. Johnson's—General Kidd, death took place suddenly from rupture of the aneurism, without any previous symptom of its existence. The same happened in Dr. Reynaud's case. In a patient of Cruveilhier's, severe asthmatic paroxysms took place; with a sense of constriction, particularly about the heart, and a peculiar sensation in the arm-pits. These symptoms, together with hardness, fulness, and occasional intermittence of the pulse, and suffusion of the face, led to the suspicion of organic disease in the heart. But, at that time, auscultation was not cultivated. The hardness and fulness of the pulse arose from hypertrophy of the left ventricle.

*Case.*—A man, aged thirty-two, was admitted into St. Thomas's Hospital on the second of March, 1826;—on account of palpitation of the heart, especially on moving or lying down; inability to lie in any other position than on his back; sudden starting up during sleep; constant dyspnœa, and cough, with a little mucous expectoration. The pulse was regular,—not much quicker than natural; but exceedingly weak. He had discharged large quantities of tape-worm, by means of oil of turpentine; and had suffered severely, during the preceding winter, from rheumatism; of which he still complained. These symptoms gave no information as to the nature of his disease; they led to a suspicion only of some affection of the heart. I was not at that time well practised in auscultation; but found the ventricular impulse of the heart very strong all over the right half of the cardiac region; and therefore concluded, that the disease existed in the right ventricle. In two months, under rest and moderate antiphlogistic treatment, he became much better, experienced less palpitation and dyspnœa; could lie on both sides; and was stronger. The ventricular action was no longer strong on the right side; but was now both loud and strong in the lower part of the left. I could thus form no opinion as to the seat or nature of the disease. The dyspnœa, after this time, gradually increased for a fortnight; and he then died.

On opening the body, two aneurisms were found at the upper part of the left ventricle; but on the right ventricle was a tumour or large tubercle, the size of a pigeon's egg, with several smaller ones. The force originally observed in the right half of the cardiac region was now explicable, although the aneurisms sprang from the left ventricle. The aneurisms, when I first saw him, were probably not large enough to occasion symptoms so considerable as the tumour on the right ventricle; but, as they increased, decided symptoms necessarily arose in the left half of the cardiac region;—much exceeding those produced in the right by the tumour.

*Aneurism of the Auricle.*—I have met with a case of aneurism of an auricle;—a part which has never, I believe, been recorded to have laboured under this disease. There was hypertrophy and dilatation of the left ventricle, with extreme ossification and cohesion of the mitral valve;—the auriculo-ventricular opening

<sup>a</sup> "Morbid Anatomy;" Chapter 2; Section 4.

<sup>b</sup> See Page 859.

being proportionally reduced. The sinus of the left auricle formed an aneurism of large size, with very dense and thick layers of fibrin for its walls; and these had reduced its cavity to a very small capacity. The action of the ventricles had been strong, loud, and extended; and a dull sound, more extensive than natural, had been given on percussion of the cardiac region. The hypertrophy and dilatation of these parts, were pronounced during life. The pulse had been feeble, and the breathing very difficult; and the legs had swelled. The feebleness of the pulse, notwithstanding the strong action of the left ventricle, arose from the small quantity of blood discharged into the left ventricle to be propelled into the aorta; but had not been ascribed to this cause, as there was *no bellows-sound or thrill*;—neither the aneurism, nor the constriction of the left auriculo-ventricular opening, had been suspected. The absence of bellows-sound arose from the opening, though constricted, being still perfectly commensurate with the reduced capacity of the auricle; to which it retained its natural proportion; and thus afforded a sufficient outlet to the small quantity of blood to be discharged. The fact is as interesting, as the situation of the aneurism is extraordinary.

The case proves, for the first time, that cardiac aneurism is not peculiar to the left ventricle, nor even to the ventricles: and I may remark, that my case of ventricular aneurism is an additional argument to those already on record and adduced by Dr. Reynaud, of the error of Breschet in supposing aneurisms to be generally situated towards the apex of the ventricle. In this case, the two aneurisms were lined by a smooth membrane, continuous with that of the ventricles; and thus afforded also an additional proof that, in these cases, the internal membrane is not necessarily injured;—as Breschet must also imagine, when he calls these “*false consecutive aneurisms*,” though it must be allowed that he did not consider the ten cases with which he was acquainted, sufficient to afford a perfect history of the disease.

#### SECTION IV.—CORONIC CHANGES THE RESULT OF INFLAMMATION.

*Induration.*—Hypertrophy of the heart, I have stated,<sup>a</sup> appears to be of an inflammatory nature. With it is generally united some degree of induration. Sometimes induration exists, alone, or in great proportion to the hypertrophy. I believe it is attended by palpitation, a full and rather hard pulse, and frequently by pain in the heart. We must suppose it inflammatory.

*Softening.*—On the other hand, the substance of the heart is sometimes softened; and the pulse and action of the heart are then feeble and frequent, dropsy takes place, and a disposition to fainting; and the heart is generally found also dilated, and of a deeper or paler colour than usual. This state also may be the result of inflammation; as softening of other organs, beyond all question, frequently is. Yet softening of the heart and all other parts, and even gangrene, probably may occur without inflammation; and sometimes when it occurs with inflammation, the inflammation may not be its cause, but only one of the circumstances of a peculiar condition.

Very acute inflammation of every part generally, I believe, induces a softened state: and, although a softened state may also result from a chronic inflammation, the latter generally causes induration. This is seen with regard to the various muscles of the body, as well as to the various internal organs.

Greatly as modern pathology has been improved by the knowledge that many diseases, formerly not regarded as inflammatory, are so essentially, or to a certain extent; and greatly as medical practice has been improved, by the administration of antiphlogistic measures in such cases, I am satisfied that we are now rather too prone to believe affections nothing more than inflammations, and to treat them only as such;—that many so regarded are not at all inflammatory; or have inflammation,

<sup>a</sup> See Pages 851, 852, 856, and 857.

not as a fundamental state, but merely as one circumstance among the morbid actions; or really have inflammation as a consequence; and that the hope of curing them by antiphlogistic measures alone is vain;—whatever relief may be effected by lessening the inflammation which accompanies them.<sup>a</sup>

The deep-coloured and the pale softening of the heart, distinguished by Laennec,<sup>b</sup> occur, according to Bertin, the former as an acute, the latter as a chronic, affection. The chronic is often an attendant upon general cachexy; the acute, on pericarditis.

*Abscess and Ulceration.*—Abscess and circumscribed ulceration are sometimes found. The latter may commence in the lining membrane, or in the pericardium. Whether it be the result of an abscess of the heart, or originate in one of these membranes, it may proceed to perforation; or to such attenuation that rupture ensues,—perhaps on some effort.

*Gangrene.*—I have not read of gangrene of the heart: but it has been seen soft and black, without any gangrenous smell, from excessive inflammatory congestion of blood; and Cruveilhier gives a view of a heart beset with black patches of congested blood, similar to those observed in what is absurdly called “apoplexy of the lungs.”<sup>c</sup>

## SECTION V.—RUPTURE OF THE HEART.

Harvey is said, by Morgagni, to have first noticed rupture of the heart. Abundant cases of rupture of the heart, independently of ulceration, are on record; and are compared to rupture of the arteries, arising from violent muscular effort; though generally there is also a want of firmness in the organ.

*Usually in the Left Ventricle.*—They may occur in every part, but usually happen in the left ventricle; where the most forcible muscular contraction takes place; and a spot too thin, or soft, or ulcerated, is most likely to occur, and is most exposed to violence; if the heart is made to act forcibly, by mental or muscular causes. It is the apex or its vicinity,—naturally the thinnest part of the ventricle, that usually gives way in general softness or thinness of the organ. Death is usually instantaneous; but sometimes does not happen for several hours;—differences also observed when the heart is wounded.

*Case.*—An instance of rupture of the heart was witnessed by me, in company with my friends Dr. Roe and Mr. Alcock. The rupture was a zigzag fissure in the front of the left ventricle; not at once discerned on bringing the heart into view, but which had filled the pericardium with blood. The patient,—Mr. Hayes, a highly respectable general practitioner, in Charlotte Street, Fitzroy Square,—corpulent and about sixty years of age, had suffered three attacks of pain about the præcordia with dyspepsia and vomiting, during six days; but had gone out as usual in the intervals. On the morning of his decease, a fourth attack of pain, referred by him to the heart, took place before he rose in the morning; and he gave his assistant directions for preparing him a fomentation. Presently his bell rang violently, and was instantly answered; but he was found dead. The heart was very soft; the fat external to the abdomen excessive; and considerable adhesions existed among the abdominal viscera.

*Rupture of the Right Ventricle.*—While numerous instances of rupture of the left ventricle are on record, we have very few of the rupture of the right. Yet George the Second perished suddenly of this accident, in 1760: and so, in 1730, did the Princess of Brunswick; whose case, no less than the celebrated one of George the Second, is referred to by Morgagni.<sup>d</sup>

<sup>a</sup> This I stated in my work on Hydrocyanic Acid; Page 105. Andral has many excellent remarks to the same purpose, in his work on Morbid Anatomy. [Translated by Drs. Townsend and West.]

<sup>b</sup> See his Treatise on Diseases of the Heart, translated by Dr. Forbes. Part 2; Book 2; Chapter 9; Paragraph 1. (Third Edition; Page 620.)

<sup>c</sup> See Page 764.

<sup>d</sup> “De Sedibus et Causis Morborum;” Liber II. Epistola Anatomico-Medica, xxvii. 7.

*Rupture of the Valves.*—The valves alone sometimes suddenly give way; and I believe that immediate extreme dyspnoea and rapidity of pulse, are the usual effects of an extensive injury of this kind. They split either from intensity of disease, from mere fragility, or from some violent effort;—exactly the circumstances in which frequently the inner, or inner and middle coats of an artery crack, and give rise to aneurism. An engraving of a split aortic valve, is given in Dr. Baillie's work. I saw an instance in which the same valves were beset with grains of earth, and obstructed the course of the blood; when suddenly, without obvious cause, all the symptoms were aggravated, and the patient died in a few days; two of the aortic valves were found rent. I have already referred to these two cases.<sup>a</sup> In the "*Medical Gazette*," for June 20, 1829,<sup>b</sup> an instance of rupture of the tricuspid valve is described. The heart was variously diseased, but not particularly the tricuspid valve: and, under an exertion, a snap had been felt in the

"*Histoire de l'Académie des Sciences*;" 1732. In the same volume, is recorded an instance of rupture of the left ventricle.

Smollett, in his "*History of England*" (Volume 5, Page 418), makes two egregious blunders, in his account of the king's death. He says:—"On the twenty-fifth day of October, 1760, George, King of Great Britain, *without any previous disorder*, was early in the morning seized with the agony of death, at the palace of Kensington.

"He had risen at his usual hour, drank his chocolate, and inquired about the wind—as anxious for the arrival of the foreign mails: then he opened a window of his apartment; and, perceiving the weather was serene, declared he would walk in the garden. In a few minutes after this declaration, while he remained alone in his chamber, he fell down upon the floor: the noise of his fall brought into the room his attendants, who lifted him on the bed; when he desired, in a faint voice, that the Princess Amelia might be called; but before she could reach the apartment, he had expired. An attempt was made to bleed him, but without effect; and, indeed, his malady was far beyond the reach of art; for when the cavity of the thorax was opened, and inspected by the serjeant-surgeons, they found the right ventricle of the heart actually ruptured, and a great quantity of blood discharged into the pericardium; so that he must have died instantaneously, in consequence of this effusion. The case, however, was so extraordinary, that *we question whether there is such another instance upon record*. A rupture of this nature appears the more remarkable, as it happened to a prince of healthy constitution, unaddicted to excess, and far advanced beyond the period of life when the blood might be supposed to flow with a dangerous impetuosity."

Now we have seen, that a member of the very same family,—the Princess of Brunswick, died not only of a rupture of the heart, but of a rupture of the very same ventricle of the heart, in 1730; and Dr. Smollett's reflections upon the improbability of rupture from the moderate impulse of the blood in the king are groundless; since ruptures of the heart and aorta rarely occur under the most violent impulse, unless there be disease of substance; and when the latter exists, they may occur under the most feeble impulse of the blood. Rupture of the blood-vessels of the head is most common in the aged; as their coats are most frequently diseased in the decline of life.

So far is it from being correct that his Majesty had experienced no particular disorder, that Dr. Nicholls, the king's physician,—in his account of the dissection, in the "*Philosophical Transactions*" for 1762,—informs us, that "His Majesty had for many years complained of frequent distresses and sinkings about the region of the heart; and his pulse was of late years observed to fall very much upon bleeding."

As if errors were destined on this point, Dr. Forbes (in his translation of Laennec, Part 2; Book 2; Chapter 14) states, that "George the Second of England is often said to have fallen a victim to the same accident as Philip the Fifth of Spain (rupture of the heart); but his death was occasioned by rupture of the aorta."—The words of Dr. Nicholls, however, are the following:—"The pericardium was found distended with a quantity of coagulated blood, nearly sufficient to fill a pint-cup; and, upon removing this blood, a round orifice appeared in the middle of the upper side of the right ventricle of the heart, large enough to admit the extremity of the little finger. The ventricles were found absolutely devoid of blood, either in a fluid or coagulated state."

Aneurism of the aorta existed, but was not ruptured. The middle and interior coats were split, but the external was entire,—as in the first stage of false aneurism; and merely an elevation was produced.

It is at this time amusing to read Junius's letter, calculating on hereditary tendency, and hinting, in 1770, to George the Third (who died in 1820), the possibility of a long minority; as "every true friend of the House of Brunswick sees, with affliction, how rapidly some of the principal branches of the family had dropped off." (Letter 37.—"To the Printer of the Public Advertiser.")

<sup>a</sup> See Page 834.

<sup>b</sup> No. 81; Volume 4; Page 78.

heart; immediate rapidity and irregularity of pulse had occurred, with syncope, and (I presume) dyspnoea; and the patient had died in six days.

*Effects of Ruptured Valves.*—If the rupture is not extensive, the irritation of the laceration, and the imperfect function of the valve, give rise to chronic disease;—such as hypertrophy of the substance of the heart, dilatation, and structural change of the valves themselves; and death does not occur for some time. Dr. Abercrombie<sup>a</sup> mentions an instance, in which, after a severe fall on the left side of the chest, death took place in five months; and an aortic valve was found torn at its base,—so as to give the appearance of a ring; and the left ventricle was hypertrophied and dilated. Morgagni found an aortic valve ruptured.<sup>b</sup>

Sometimes the “chordæ tendinæ” of the valves are ruptured. A case is recorded by Mr. Adams, in the “Dublin Hospital Reports,” Volume 4; Page 404. The patient lived about a month. Corvisart mentions three instances of their laceration during violent efforts. Laennec found a tendon of the mitral valve ruptured, in eccentric hypertrophy of both ventricles.<sup>c</sup> M. Bouillaud found a “columna carnea” of the tricuspid valve torn through.

*Generally complicated with Disease of the Heart.*—In all these instances of rupture of the valves and their attachments, there has generally existed some disease of the heart; and most frequently even of the valve itself. But occasionally—just as in rupture of the substance of the heart, and of the inner and middle coats of the aorta—no diseased appearance is discernible: although one must suppose a morbid friability, at least, in those cases where no external force, no effort of voluntary muscles, and no mental excitement,—some one of which is commonly the cause of rupture,—took place.

I met with an instance of a circular hole in two aortic valves, on either side of their septum, from original defective formation. Morgagni once found a hole in one of the leaves of the mitral valve.<sup>d</sup>

## SECTION VI.—STRUCTURAL DISEASES OF THE HEART.

*Ossification.*—The induration of the heart occasionally amounts to a cartilaginous or osseous state. But these changes are almost always originally seated in the lining membrane, or in the pericardium, or in the subjacent cellular membrane. A spot of the heart or its membranes is sometimes so changed; sometimes nearly a whole cavity becomes a bony case. Mr. Burns declares, that he once saw not only complete ossification of the pericardium, but also the ventricles ossified as firmly as the skull, except for about an inch at their apex. The “chordæ tendinæ” are occasionally ossified.

*Ossification of the Coronary Arteries.*—The coronary arteries are sometimes ossified; and, not unfrequently, the kind of suffering denominated “angina pectoris” is the result. But they may be ossified without such a result; and “angina pectoris” may exist with various structural diseases of the heart, or without any.

*Fatty Degeneration of the Heart.*—I once saw the muscular substance of the heart completely changed, except at the surface, to fat. A mere layer of red muscular structure covered the internal and external parts of the heart, and the “columnæ carneæ” within, every spot was fatty matter. The patient had been subject to frequent attacks of syncope; palpitation, irregular and small pulse, with dyspnoea, and anasæra.<sup>e</sup> There were five pulmonary veins.

<sup>a</sup> In a paper on the Pathology of the Heart; published in the “Transactions of the Medico-Chirurgical Society of Edinburgh;” Volume 1; Page 49.

<sup>b</sup> Epistle 24; 10.

<sup>c</sup> See his Treatise on Diseases of the Heart, translated by Dr. Forbes. Part 2; Book 2; Chapter 21; Case 47. (Third Edition; Page 668.)

<sup>d</sup> Epistle 23; 6.

<sup>e</sup> A case will be found in the “Dublin Hospital Reports;” Volume 2. The symptoms were the same as in my patient. A case was previously given by Dr. Duncan, Jun., in the “Edinburgh Medical and Surgical Journal,” for January, 1816; Volume 12; Page 43.

*Atrophy of the Heart.*—Sometimes the heart wastes,—is atrophied;—becoming small and wrinkled. This is often, though not always, observed after chronic diseases; and especially after phthisis. Pressure, from pericardial effusion or any other cause, has the same effect. The walls of an atrophied heart, it is said by Dr. Bertin,<sup>a</sup> may be thinner or thicker than usual, or of their usual dimensions;—their thinness being occasioned by dilatation, their thickness by narrowing, of the cavities. But it appears to me, that if the walls are thickened, we are not justified in pronouncing the smallness of the heart an atrophy; as the external smallness of dimension may arise from violent contraction at death; and, if the walls are dilated, that we are not justified in calling the thinness “atrophy;” because the original quantity of substance may be in them, and only spread out. If the whole heart weighs less than is natural, then only (I think), we ought to say that the organ is atrophied; and, even then, the smallness of the organ may be an original defect; unless indeed it appears wrinkled, like a shrivelled apple,—to use Laennec’s comparison.

*Scirrhus and other Deposits.*—The heart has been seen cancerous; it has contained, in its substance and in its cavities, cysts, and true hydatids;<sup>b</sup> and, in its substance, scrofulous tubercles, scirrhus,<sup>c</sup> bone, encephaloid deposit, &c.

I once opened a person who died of repeated hæmoptysis. In the substance of the lungs were hard patches of the deepest red; and, in the ventricles of the heart, innumerable thin globular cysts—containing bloody fluid, and attached by a peduncle—could be squeezed out from among the “columnæ carnee.”<sup>d</sup>

*Cyanosis.*—Upon the state of the heart which gives rise to a mixture of venous and arterial blood,—the state termed “cyanosis,”<sup>e</sup> I have little to say. It is usually a congenital malformation; upon which the works of Dr. Farre and Mr. Burns leave nothing to be desired.<sup>f</sup> I have already remarked, that I have seen the admixture rather suddenly begin to increase, in adult age. Bertin believes, that the admixture has occasionally commenced after birth, from an ulcer in the auricular or ventricular septum;—throwing the two corresponding cavities into one.<sup>g</sup> In most cases, the right auriculo-ventricular or ventriculo-arterial opening becomes narrowed; and the right auricle or ventricle or both are dilated and hypertrophied; and the usual ill consequences of that affection are, sooner or later, experienced.<sup>h</sup>

<sup>a</sup> In his “Treatise on Diseases of the Heart,” Book 2; Section 2; Chapter 3; Paragraphs 1 to 3. (Pages 389 and 390 of the Paris Edition of 1824.)

<sup>b</sup> In the “Medico-Chirurgical Transactions,” Volume 11, is a case of cysts or hydatids in the substance of the heart. Three apparently true animal hydatids, were found in a heart by Dr. Andral (“Précis d’Anatomie Pathologique,” Tome 2, Page 332). Dr. Abercrombie, in the “Edinburgh Medico-Chirurgical Transactions” (Volume 1, Page 53), mentions having found a cyst in the left auricle, apparently containing others collapsed in a dark thick fluid. I may mention that, at Page 58, he gives a curious case of partial cohesion of the sides of the right ventricle, an inch and a half from the bottom;—producing a small cavity.

<sup>c</sup> There has been just placed in the museum of St. Thomas’s Hospital, by one of the Physicians, an adult heart, in which the walls of the left ventricle contain many deposits of scrofulous matter,—surrounded by white and almost cartilaginous induration.

<sup>d</sup> I gave the dissection in the “Annals of Medicine and Surgery,” 1816. Laennec therefore erroneously considered himself the first who described what he terms “the globular excrescence.” See Dr. Forbes’s Translation of his “Treatise,” Part 2; Book 2; Chapter 21. (Third Edition; Page 665.) And, indeed, he refers to numerous authors for what appear to have been analogous formations. For the details of this case, see Page 765.

<sup>e</sup> From *κυανος*, blue.

<sup>f</sup> The malformations referred to in Dr. Farre’s work, together with my own morbid specimens of diseased heart, are all deposited in the museum of St. Thomas’s Hospital; and, with numerous others, constitute (perhaps) an unrivalled collection of cardiac lesions.

<sup>g</sup> See his “Treatise on Diseases of the Heart,” Book 2; Section 6; Article 1. (Page 433 of the Paris Edition of 1821.)

<sup>h</sup> See Bertin’s “Treatise on Disease of the Heart,” Book 2; Section 6; Article 1. (Page 436 of the Paris Edition of 1824.) He ascribes the circumstance to the excitement of the right half of the heart by the admission of a portion of arterial blood into it.

A high degree of obstruction in the right auricular or ventricular opening, or in the lungs, will, without any malformation, produce a blueness, approaching to blackness, in the countenance, long before death.

*Preternatural Situation of the Heart.*—Preternatural situation of the heart occasionally occurs; sometimes congenitally; but oftener in consequence of the morbid presence of solid, fluid, or æriform substances in the left cavity of the thorax,—pushing the heart to the right;—a circumstance which is by no means uncommon. Dr. Abercrombie mentions a case in which the right lung had become solid; and the left, dilated extensively to perform the function of both, had pushed the heart to the right.<sup>a</sup> Increased bulk of the heart itself, or pressure from other parts,—either above (as from aortic aneurism), or from abdominal enlargement below,—will likewise occasion other changes in the situation or the direction of the heart. These may be recognised by the touch.

*Fibrinous Coagula.*—Although the greater part of the fibrinous coagula observed in the heart and large vessels are produced after death, some are unquestionably produced during life; for they are occasionally organic, and adhere by vessels to the substance of the heart; and symptoms evidently arising from obstruction to the course of the blood, appear during life;—exactly as we find to be the case from the existence of organized coagula in arteries and veins at a distance from the heart. Sudden paralysis of an extremity, attended by loss of pulse in it, and sometimes at length even mortification, has frequently occurred from the production of coagula in arteries.<sup>b</sup>

## SECTION VII.—NEURALGIA OF THE HEART.

Like various parts of the body, the heart is subject to neuralgia. I had a case of this kind, where the pain was intense; not only affecting the region of the heart, but darting at the shoulders and back; sometimes dull and aching, at others stabbing; not increased by motion or posture; and unaccompanied by any stethoscopic signs. It occurred in a middle-aged woman, at St. Thomas's Hospital; and the symptoms were removed by iron, but afterwards (I believe) returned.

A second case has occurred to me in the person of a lady, who appears to have laboured under the disease very many years. Besides a constant aching in the lower part of the cardiac region near the sternum, there are frequent stabbing pains,—plunging (to use the expression of most persons afflicted with neuralgia); so that she is compelled to rise and walk the room almost every night. These occur during motion and rest; but most severely during motion. They shoot in all directions, and occur occasionally in distant nerves. As soon as they are over, she is apparently well; and, when they are not very troublesome, sings, dances, or takes horse-exercise. In the first case, the ear discovered nothing morbid in the heart: in this, a slight ventricular bellows-sound is heard. Andral mentions a dreadful case of this kind, which proved fatal; without leaving any trace of disease in the heart, or its dependencies.<sup>c</sup>

## SECTION VIII.—ANGINA PECTORIS.

*Symptoms.*—By “angina<sup>d</sup> pectoris” is meant a sudden violent pain, in some part of the chest near the heart, and especially at the sternum;—a pain which causes the patient to stand still if he be walking, and induces a sensation as if he were about to expire. The pain, at first, is felt only at one spot,—in the situation I have mentioned; but at length it extends to the shoulder, darts through to the spine, goes down the arm, and occurs at the end of the fingers. In general the

<sup>a</sup> “Edinburgh Medico-Chirurgical Transactions,” Volume 1; Page 65.

<sup>b</sup> See Bertin's Treatise on the Heart, Page 417; Mr. Adams, in the “Dublin Hospital Reports,” Volume 4, Page 432; “Edinburgh Medico-Chirurgical Transactions,” Volume 3, Page 1; and compare with these the “Transactions of a Society for the Improvement of Medical and Surgical Knowledge,” Volume 3, Page 418.

<sup>c</sup> “Précis d'Anatomie Pathologique,” Tome 2; Page 344.

<sup>d</sup> From *αγγεον*, to strangle.

pain is confined to the left side; though there are a few cases where it has extended to the *right* shoulder, and down the *right* arm, and even down the front of the loins; but that is usually after it has existed for some time (longer or shorter) at the sternum, and down the left arm. There is not necessarily palpitation; for we may have this affection without any palpitation at all.

*Pathology.*—Dr. Haygarth, of Bath, has collected a vast number of cases of this description; and has inferred that these symptoms are characteristic of disease of the coronary arteries. He does not say “characteristic of *ossification*,” as some make him; but “characteristic of *disease* of those arteries;”—whether it be induration, or the formation of cartilage, or of bone. But it is now ascertained, that “*angina pectoris*” does not characterize any particular affection of the heart. We may have it without ossification, or any perceptible disease of the coronary arteries; and, on the other hand, we frequently find ossification of the coronary arteries, without the symptoms called “*angina pectoris*.” *Angina pectoris* is very well described by Dr. Heberden, in the second volume of the “*Transactions of the College of Physicians*.”<sup>a</sup> It is not one of the common symptoms of disease of the heart. In the greater number of instances in which the heart is affected with disease of any kind, we have not the symptoms of “*angina pectoris*,” and although it is a fact, that we frequently have these symptoms when there is ossification of the coronary arteries, or great ossification of the mouth of the aorta; yet it is also a fact that we may have them in almost any disease of the heart whatever; and also that we may have them without any ossification at all.

*Distinguished from Gastrodynia.*—Such symptoms, it is now well known, will take place without any disease of the heart. A few years ago, there were published some cases, accurately described as “*angina pectoris*,” but in which no disease of the heart was found after death. The truth is, I believe, that *gastrodynia* (spasmodic pain of the stomach) frequently resembles this affection. The left side of the stomach is situated close to the heart; and a violent pain of the stomach frequently shoots upward; sometimes as far as the shoulder, and even down the arm. Cases of pure spasmodic or neuralgic pain of the stomach, will give way to stramonium, prussic acid, and remedies of that description; and are shown to be diseases of the stomach, not only by their ceasing entirely, on the exhibition of remedies calculated to relieve functional disorders of the stomach, but by acidity, perhaps vomiting; and by various other symptoms, indicating disease of the *stomach*, and not of the *heart*. In such cases, I have known persons seized with a violent pain, when they have moved quickly;—just the same as when there has been disease of the heart itself.

*Distinguished from Neuralgia.*—The heart is certainly subject to pain of a neuralgic character. I have seen several cases of persons who have had violent pain, at different times, in the region of the heart; and the difference between it and what is called “*angina pectoris*,” I have found to be this;—that the latter is only felt when the patient moves about; whereas a neuralgic pain is felt quite as severely when the patient is sitting still. Frequently, too, there is pain darting in other distinct nerves of the body. The pain is of a stabbing character; and although it may be made worse by the patient jolting himself about, yet, when he is perfectly still, it will frequently come on in the most violent way. Another diagnostic mark is, that neuralgia is not particularly disposed to dart through the left arm; nor is it attended with a “*dying*” sensation;—as though the individual were about to expire.

*Treatment.*—I have relieved “*angina pectoris*,” more by prussic acid than by any other remedy. If there be organic disease of the heart, we cannot relieve it to the same extent as we can a *neuralgic* affection of the organ; and I do not know that I ever did much good in such cases.

## CHAPTER IV.

## DISEASES OF THE AORTA.

## SECTION I.—AORTITIS.

*Symptoms.*—I formerly mentioned,<sup>a</sup> that the lining membrane of the heart and aorta was subject to inflammation, and sometimes simultaneously with the pericardium. In the case of the heart, I believe that the symptoms are, increased general sound, force and frequency of action, with more or less pain or uneasiness: and when the former continue for a length of time, without the peculiar auscultatory signs of organic disease, or proportionate pain on pressure (as observed in pericarditis), we certainly may infer the existence of this inflammation.

The lining membrane of the aorta is generally inflamed at the same time; and when the affection extends along the descending portion, there is frequently a sense of smarting in the direction of the spine, and in the abdomen a violent pulsation, not only of the aorta, but even of the iliacs; without any perceptible enlargement of the vessels, the existence of any tumour in its neighbourhood, or such a smallness of any of the arteries as might render it probable that the aorta was narrowed in any part, and thus forced into violent pulsation.

*Causes.*—Aortitis seems caused by all the circumstances which produce inflammatory affections of the heart, and perhaps by disease of the heart itself. Either hypertrophy of the left ventricle gives rise to inflammation of the aorta, or the converse happens, or they spring up together; for they are frequently conjoined.

*Morbid Signs.*—Of the intensely bright redness of the inner surface of the inflamed aorta, and the impossibility of ascribing it to any thing but inflammation, I formerly spoke;<sup>a</sup> as well as of the occasional effusion of fibrin. It appears as a red stain; and sometimes the middle coat appears more loaded with blood than usual.

*Chronic Changes.*—But we far more frequently discover the chronic change of structure in this vessel. Yellow spots are seen every day: often a yellow curdy substance can be squeezed through the inner membrane, under which it is deposited;—the membrane having become friable, and under distension giving it issue. Sometimes the deposition projects into the canal of the artery, like a tubercle. Frequently spots and patches of bone are seen bare, and in contact with the blood: originally deposited below the inner membrane, I believe, and exposed by its cracking and becoming destroyed. Sometimes all the coats are thickened and indurated. Ulceration is occasionally seen, and fatal hæmorrhage has been thus produced;—the extenuated outer coat (perhaps the only one remaining) giving way under some exertion or strong action of the heart. More commonly the aorta, like other arteries, dilates.

## SECTION II.—ANEURISM OF THE AORTA.

*Varieties.*—Either all the coats dilate together throughout the circumference of the vessel, or in one spot, so that a pouch is formed: or, the inner or middle coat cracking, or (which is less frequent) ulcerating, the blood distends the external into a pouch; and this gradually gives way also, and hæmorrhage occurs: or the surrounding parts adhere to the vessel; and thus hæmorrhage is prevented, till these likewise ulcerate or burst. Occasionally the three coats first dilate generally or partially;

<sup>a</sup> See Page 831

and then the internal and middle give way, and the external continues to dilate alone. The middle coat often cracks at the same time as the internal.

*Condition of the Vessel.*—Both the simultaneous dilatation of the three coats, and the rupture of the internal, nearly always arise from far more than mere debility of structure,—generally from some disorganization: at least some change of colour, some deposition, or unusual appearance, is nearly always observed at the same time.

*True and False Aneurism.*—The partial dilatation of the three coats of the aorta and other arteries, is by some termed “*true aneurism*,” while others restrict the term to the dilatation of the middle and external or of the external;—the internal or the internal and middle being ulcerated or ruptured. Those who apply the term to the partial dilatation, call the instances in which one or more coats are ruptured,—“*false aneurisms*.” Yet all allow that, whether the three coats dilate together, or only the middle and external,—the internal being cracked or destroyed, the morbid condition of the vessel giving rise to the change is much the same. If partial dilatation of all the coats occurs first, and then rupture of the inner coat in one spot of the dilatation, both kinds of aneurism exist.

*Most frequent in the Ascending Portion.*—This disease most commonly takes place in the ascending portion or the arch of the aorta;—the extension usually occurring at the anterior or lateral portions of the vessels, and inclining to the right side: and dilatation, general or partial, usually precedes the ulceration or rupture of the inner and middle coats.

*Rupture usually Transverse.*—Aneurism frequently exists without giving rise to any symptoms: and as the aorta within the pericardium is detached,—is without the possibility of surrounding parts becoming adherent to it, and preventing the escape of blood when its coats entirely give way, sudden death from this cause frequently surprises persons apparently in good health. The rupture is usually transverse, and has been seen throughout the circumference of the vessel; though limited rupture is much more common; and, when confined to the internal and middle coats, it is almost universally transverse.

If the inner and middle coats only are ruptured, blood escapes under the external; and sometimes separates it, to a greater or less distance. Laennec saw it separated from the commencement of the aorta to the iliacs;—giving the appearance, at first sight, of a septum in the middle of the vessel. When, after an interval, varying in length, the external coat ruptures, the opening may be in a different direction from the fissure in the internal and middle coats.

*Case.*—A woman was admitted by me into St. Thomas's Hospital, on account of severe pain of the left half of the head, face, and neck, and of the left shoulder. I ordered thirty leeches to be applied; and, during their application, she suddenly screamed with pain in the region of the heart, fell back, and expired. On examination, the pericardium was found distended with clear serum, and a very large coagulum of blood; which had escaped through a small longitudinal rent in the outer coat and pericardial covering of the aorta. The outer coat was separated from the internal and middle into a pouch; which contained a portion of adherent fibrin, precisely similar to the fibrin found in aneurisms, and a quantity of ordinary coagulum; without any morbid appearance of structure. In the internal and middle was a transverse slit. The latter had, no doubt, taken place some time before death; the longitudinal fissure at the moment of decease.

*Case of George the Second.*—In George the Second, the aorta had undergone the first half of this process: the internal and middle coats of the aorta presented a transverse fissure, around which was a coagulum under the external coat; which would soon likewise have burst, perhaps longitudinally,—exactly as in this case of mine; and, had no rupture of the right ventricle occurred, as I formerly described,<sup>a</sup> sudden death would ultimately have taken place, from the rupture of the aorta.<sup>b</sup>

<sup>a</sup> See Page 862.

<sup>b</sup> In the track of the aorta, we found a transverse fissure on its inner side, about an inch and a half long; through which some blood had recently passed under its external coat, and

*Mode of Rupture.*—In two instances, an aneurism of the pericardial aorta burst into the pulmonary artery. When the disease is situated in the arch of the aorta, the rupture may take place into the trachea, the œsophagus, the pericardium, or the pleura. The descending thoracic aorta usually bursts into the pleura, œsophagus, or posterior mediastinum, or even into the lungs. Aneurisms of the pectoral aorta most frequently burst into the left pleura. But aneurisms of the arch and descending aorta sometimes destroy life by compressing the organs of respiration or the œsophagus.

*Symptoms.*—When a certain size is attained by an aneurism of the ascending aorta, a tumour is usually formed at the fifth and sixth ribs of the right side: when at the anterior part of the arch, the tumour is at the third and fourth of the right side: when at the superior part of the arch, it is above the sternum and clavicles. The strongly pulsating character of the tumour shows its nature, even should the tumefaction subside considerably for a time; as happened, from repeated venesection, in three cases of this disease that I treated; and in one of which the tumour, at one time, actually pointed.

There is frequently cough, with mucous and bloody expectoration; dysphagia; dyspnoea, even orthopnoea; attacks of spasmodic suffocation; pain in the right shoulder, axilla, inner side of the arm in the course of the nerves (which may be tender), and up the right side of the neck and head. Pricking pains may be felt in the tumour.

Previously to the appearance of any tumour, there may be no sign of disease; or the signs which present themselves may be very uncertain: and persons continually perish of aneurismal rupture of the aorta, apparently in perfect health. Laennec declares the diagnosis to be difficult;<sup>a</sup> and confesses that he had frequently not suspected the disease when it existed, and suspected it when it did not exist.<sup>a</sup>

Violent pulsation of the carotids has created a suspicion of the disease; but may arise from mere excitement of the heart, hypertrophy of the left ventricle, dilatation of them, or from any obstruction to the course of the blood in other directions;—as in the descending aorta or the subclavians. Dulness of sound on percussion of the superior sternal portion of the chest, and to the right of that spot, as well as smallness and irregularity of pulse, arise from many causes. A bellows-sound or a thrilling sensation, given to the hand only or chiefly when applied *above* or to the right of the cardiac region, may justly give a strong suspicion of the disease. But neither the bellows-sound nor the thrill always occurs. In four cases out of seven that I have seen of the disease, as well as in cases of aneurism of the arteries, neither occurred.<sup>b</sup> Laennec never observed the thrill before the tumour had become visible externally.

*Diagnosis.*—Laennec, however, considers that the chief diagnostic sign of an aortic aneurism, is a strong and *single* pulsation; discernible by the ear in the region of the aneurism, synchronous with the pulse at the wrist, stronger and louder than the action of the ventricles, and unaccompanied by the sound of the auricles.<sup>c</sup> In three instances of aneurism of the aorta under the sternum, he was

formed an elevated ecchymosis. This appearance showed the true state of an incipient aneurism of the aorta; and confirmed a doctrine which I had the honour to illustrate by an experiment, to the satisfaction of the society, in the year 1728; namely, that the external coat of the aorta may (and does) often control an impetuosity of the blood, capable of breaking the internal or ligamentous coat.—*Extract from a Paper read to the Royal Society; November 26, 1761. By Frank Nicholls, M. D., F. R. S., Physician to his Majesty.*

<sup>a</sup> See his Treatise on Diseases of the Chest, translated by Dr. Forbes. Part 2; Book 2; Chapter 25; Section 3; Subdivision 3; Head "Signs." (Third Edition; Pages 689 to 692.)

<sup>b</sup> Laennec states, that a bellows-sound occurs frequently in aneurisms of the aorta and other arteries; but that, as it is not constant, and may be heard sometimes when no aneurism exists, it cannot be considered among the signs of aneurism.—("Treatise on Diseases of the Chest," translated by Dr. Forbes. Part 2; Book 2; Chapter 25; Section 3; Subdivision 3; Head "Signs," Pages 690 and 691 of the Third Edition.)

<sup>c</sup> See Dr. Forbes's Translation of Laennec's Treatise. Part 2; Book 2; Chapter 25; Section 3; Subdivision 3; Head "Signs." (Third Edition; Pages 690 and 691.)

(according to Bertin<sup>a</sup>) mistaken: but would not have been, Bertin contends,<sup>a</sup> had he applied the stethoscope over the sternum. Bertin asserts, that whenever an aneurism of the aorta exists, as well as of any other artery, a strong single sound may be perceived in it, distinguishable also from the beating of the heart by its greater intensity;<sup>b</sup> and he maintains, that if the stethoscope is applied *upon the sternum*, in aneurism of the substernal aorta, the disease may be recognized with facility before it is visible;<sup>c</sup> and that Laennec does not appear to have applied the instrument in this situation.<sup>a</sup> Bertin discovered the disease in two cases in which there was no tumour.<sup>d</sup> Aneurism of the descending aorta, he considers, may be recognized by the same phenomenon at the pectoral spine.<sup>e</sup>

The aneurismatic pulsations (Bertin adds) are so peculiar, intense and sharp, that they cannot be described; and a person who has once heard them can never mistake them.

I once discovered aneurism of the ascending aorta and of its arch, before any pulsating tumour appeared, by this strong pulsation to the right of the sternum and at its upper part, synchronous with the pulse, stronger and louder than the ventricular action of the heart. But then the aneurism was very large, though it formed no external tumour;—having extended chiefly backwards and to the right.<sup>f</sup> Yet neither in that case, nor in those in which a pulsating tumour existed, can I say the pulsations appeared peculiar. The pulsations, as heard, were double;—the sound of the aneurism was (of course) heard with the action of the ventricles, but the sound of the auricles was also distinctly heard in the region of the aneurism; and the frequent occurrence of this circumstance is mentioned by Laennec. The same was the fact in the cases with tumour, when the stethoscope was applied to the latter; although the impulse was of course single. In that case a bellows-sound was heard; and in it, and also in all the cases with tumour where the bellows-sound was heard, the sound was double;—occurring both at the moment of the pulse and afterwards; and that sound which was heard after the pulse, was much louder in the aneurism than in the heart.

I presume that a bellows-sound is heard *with* the pulse, if the mechanical state of parts produces any difficulty to the course of the blood, or if there is general dilatation of the vessel as well as aneurism; so that the blood is checked when flowing on into the narrower healthy portions. The second bellows-sound possibly arises from the elasticity of the parts impelling some of the blood from the dilated portion, after the action of the left ventricle.

*Treatment.*—In a case of this description, nothing can be done but to enjoin perfect rest, and deprive the patient of all stimuli;—giving him that nourishment which is least likely to quicken the pulse. Bleeding, from time to time, is exceedingly useful; as it relieves the sufferings of the patient very much. We know that, in aneurism, nature fortifies the part, by producing adhesions around it; but there is frequently more inflammation than is useful; and there are frequently

<sup>a</sup> See his *Treatise on Diseases of the Heart*. Book 1; Chapter 2; Article 2; Section 3. (Page 144 of the Paris Edition of 1824.)

<sup>b</sup> See his *Treatise on Diseases of the Heart*. Book 1; Chapter 2; Article 2; Section 3. (Pages 143, 144, and 146 of the Paris Edition of 1824.)

<sup>c</sup> See his *Treatise on Diseases of the Heart*. Book 1; Chapter 2; Article 2; Section 3. (Page 145 of the Paris Edition of 1824.)

<sup>d</sup> See his *Treatise on Diseases of the Heart*. Book 1; Chapter 2; Article 2; Section 3. (Pages 143 and 144 of the Paris Edition of 1824.)

<sup>e</sup> See his *Treatise on Diseases of the Heart*. Book 1; Chapter 2; Article 2; Section 3. (Pages 145 and 146 of the Paris Edition of 1824.)

<sup>f</sup> I lately had a patient with enormous aneurism of the ascending aorta. It extended to the left, upwards, and backwards; so that its summit adhered to the highest ribs under the left scapula; and a pulsation, with a double sound, existed many months before death at the lower right anterior part of the chest; corresponding with the situation of the apex of the heart on the left. No aneurism, nor any thing but the healthy lungs, existed at the seat of pulsation: and this must have been produced by the reaction of the aneurism from the upper posterior left ribs, upon the lower anterior right part of the chest. No one suspected aneurism.

pricking, stabbing pains, together with violence of the heart's action; and all these are diminished by bleeding. The blood is buffy and cupped, in such cases; because there is inflammation going on. It is of the greatest use to bleed from time to time; and to keep the patient low and quiet. These are not cases to be neglected. We may not be able to save life; but we may diminish the pain very much.

## BOOK V.

### DISEASES OF THE CHYLOPOIETIC VISCERA.

---

#### CHAPTER I.

##### DISEASES OF THE PERITONÆUM.

###### SECTION I.—PERITONITIS.

*Symptoms.*—The first disease of which I shall speak, after passing the diaphragm, is inflammation of the peritonæum;—"peritonitis." It is, of course, attended by pyrexia,—general feverishness.<sup>a</sup> Although the whole body is hot, yet generally the abdomen is hotter than other parts. The pulse, for the most part, is rather small. It is quick, sometimes wiry, sometimes hard, and sometimes soft. There is no invariable pulse in peritonitis; except that it is always quick. More frequently it is small than full; and perhaps more frequently rather hard than soft. There is great variety as to the appearance of the tongue. Sometimes it is tolerably clean,—at the utmost only whitish; sometimes it is covered with a thick, creamy mucus; and sometimes it is rather dry. There is no very great index to the disease, either in the appearance of the tongue, or in the character of the pulse; but the abdomen is always very tender on pressure; and the tenderness is too general for one to suppose that any particular organ is inflamed. One of the modes of distinguishing peritonitis from inflammation of a particular organ, is by observing that the tenderness of the abdomen is not in the seat of any particular organ whatever; but is more or less general. As the peritonæum stretches all over the abdomen, and usually a great proportion of it is inflamed, the patient is most frequently easier on his back, than in any other position; and sometimes, to obtain all the ease possible, the patient lies with his knees spontaneously raised. In general, patients cannot sit up,—on account of the abdominal viscera gravitating so much as to produce painful distension; and therefore they are easiest in a lying posture. Besides the tenderness, there are very frequently pricking pains of the abdomen,—as if needles were running into different parts; and occasionally there is a sharp, cutting pain. The abdomen is usually very tense. As it is a mere membrane that is inflamed, the bowels are not in general particularly disturbed. They are regular, or at the utmost only slightly confined; and are easily opened. There is no obstinate constipation.

Although the inflammation is usually very general, yet it may be more severe at one spot than at another. Consequently there is more pain at one part than at another; and if that part be situated over any particular organ, then the function of that organ is more or less disturbed. If, for example, at any particular period of the

<sup>a</sup> See Pages 88 and 234.

disease, the membrane covering the stomach be inflamed, vomiting is induced;—if it be the portion which partially covers the bladder, then there may be very great irritation of the urinary organs. In the former case we have vomiting; in the latter, strangury.

*Diagnosis and Prognosis.*—As the inflammation spreads, it attacks one part after another. It is the peritonæum at large that is inflamed; and therefore the tenderness is general, and the pain diffused; and any disturbance of function that exists in the abdominal viscera, is trifling in proportion to the general pain and uneasiness. It is in this way we distinguish it from inflammation of any particular organ. This disease, when acute, may last about a week before it proves fatal; but if it remit, it may of course last much longer.

*Morbid Appearances.*—After death, the appearances found are nothing but those which are usual in inflammation of a serous membrane;—for example, a quantity of serum of a whey-colour, more or less turbid, with flakes of fibrin. It is rare to find the serum bloody. The fibrin is frequently effused in a gelatinous form, both in the parietal and visceral portions; and perhaps adhesions are thrown out, so that there are bands. Now and then the secretion resembles pus; and now and then it is *really* pus. As to the redness of the peritonæum, that may be either in little stars,—a collection of red points, or diffused in patches. The peritonæum, like most other serous membranes, becomes rather thicker than usual. It is not so translucent as in health; and, now and then, it is quite pulpy. When the peritonæum covering the alimentary canal is inflamed, the redness will sometimes spread inwards, even to the villous coat; but it is very rare to find inflammation of the parietal portion spread outwards, towards the abdominal muscles. When the portion covering any particular organ is inflamed, we may find the organ itself affected; as, for example, the omentum or the mesentery; so that we may have “*omentitis*,” or “*mesenteritis*,” or any other *itis* we may choose to manufacture out of the name of the organ, and the termination “*itis*” added to it.

*Puerperal Peritonitis.*—This disease very often occurs in a puerperal state; and by some it is thought occasionally to be contagious. It is called, when occurring in that state, “*puerperal fever*.” Sometimes it will take place immediately after delivery; and sometimes many days afterwards,—whether the patient is sickly or not; and, on the other hand, it will sometimes take place during the latter period of pregnancy. Whether it be a contagious fever or not, it certainly is very often epidemic; and one might say “*endemic*,” for this disease (puerperal peritonitis) frequently prevails to a great extent at a particular period; and sometimes it prevails only in particular districts.

*Causes.*—Peritonitis is very frequently a cause of death in cancer of the womb, or various other diseases of the uterus, or of the ovaries. Whenever cancerous or other ulceration occurs in these parts, and exists for some time, the peritonæum around the ulceration comes to be inflamed; so that peritonitis is a common termination of organic diseases of these parts. Peritonitis sometimes occurs, also, after a rupture of the stomach or intestines, from ulceration. It sometimes takes place from a hernia;—either from the operation for it, or the hernia itself; from lithotomy; from “*paracentesis abdominis*,”—from wound, or mechanical injury of any sort, inflicted on the abdomen. It is frequently consequent upon the application of cold; and especially cold and moisture applied when the body is over-heated;—just the same as any other inflammation.<sup>a</sup>

*Treatment.*—The treatment of the disease is easy enough. It consists of general bleeding, followed by an abundance of *local* bleeding (by means of leeches), a rapid affection of the mouth by mercury, and keeping the bowels well purged the whole time. Cupping would produce great pain. Some prefer fomentations, and others blisters. Perhaps, it is not a matter of importance which we apply; but if we have bled as much as we dare, and still want to do more, then blisters will be

<sup>a</sup> See Page 115.

the great point of treatment. Some have recommended the external application of cold to the abdomen, in such a case; but I never employed it.

*Treatment of the Puerperal Foria.*—In that form of the disease which occurs in connection with pregnancy, or the puerperal state,<sup>a</sup> it is found that a great variety of treatment is necessary. We may have cases where there is active inflammation, demanding a vigorous antiphlogistic treatment (such as I have now mentioned); whereas, in others, the very utmost that can be borne is the application of leeches. Patients are seized with more or less pain in the abdomen; but the pulse is feeble; and if we bleed them, they will certainly sink so much the sooner. All that can be done, therefore, is to apply a few leeches, give a moderate quantity of mercury, and exhibit opium freely. So slight is the inflammation, in some of these cases, and so great the loss of power, that after death the peritonæum is not found red, but rather pale; and it will have very soft lymph lying upon it;—showing that there was an inflammatory state, but that it was attended with extreme weakness. Where the pulse is feeble, and the patient's countenance expressive of great debility, opium is far more suitable than bleeding; but if the tenderness seems to indicate bleeding, a few leeches will be all that is proper. In such a case as this, even purging has been found to be too severe a measure; but there can be no objection to a moderate quantity of mercury;—using such a preparation as will not produce an affection of the bowels (*Hydrargyrum cum Creta*, for instance). The application of warmth and moisture, will be found very serviceable. Dr. Gooch, who (as far as I can observe) has treated the subject well, strongly recommends the application of bran, moistened with hot water, and placed between two pieces of linen. A bran-poultice appears to afford very great relief.

The peritonæum, therefore, may occasionally be in an inflammatory state; attended with such extreme weakness, that the common remedies for inflammation can hardly be put in practice. This is somewhat analogous to what I mentioned respecting hydrocephalus;—that occasionally children have all the marks of that complaint, and yet no signs of inflammation are observed after death.<sup>b</sup> In the case before us, however, the membrane is inflamed; but the debility is out of all proportion to the inflammation. The treatment of peritonitis connected with the puerperal state, especially after delivery, requires to be much varied.

*Chronic Peritonitis.*—Inflammation of the peritonæum is very frequently a chronic affection: and in that case there is pain on pressure;—that is to say, there is tenderness, and likewise pricking pain. There is almost always a feeling of tension; and sometimes that is more complained of than the pain itself; but there is not necessarily any tension to be discovered; for sometimes the integuments are quite flexible. Of course there is pyrexia. The pulse is constantly quick; there is more or less thirst; the skin is generally more or less dry; the tongue is foul, and either white or yellow towards the back. The breath, in this disease, is very frequently fetid; the face sometimes assumes a doughy aspect; the bowels generally are torpid; and frequently there is ascites, from the chronic inflammation of the membrane causing an excessive secretion. As the inflammation is of a chronic character, of course the body wastes. The internal functions are very much deranged. The stools are very copious, and generally of a white-brownish colour;—not being so fully impregnated with bile as they should be; and the mesenteric glands are frequently diseased. In fact, when chronic peritonitis occurs in young persons, it is for the most part a scrofulous disease; and is connected with more or less affection of the mesenteric glands. After death, we find excessive redness and thickness of the membrane; and an effusion of serum and fibrin.

*Treatment.*—The treatment of the disease consists in the frequent application of leeches; the frequent use of the warm-bath, general or partial; warm applications,—such as the bran-poultice I mentioned, applied constantly day and night; or (as some have recommended) cold applications, frequent blisters, and a regular

<sup>a</sup> See Page 874.

<sup>b</sup> See Page 504.

purging with calomel. The contents of the intestines are very abundant. The diet should be mild. After the disease has lasted some time, if there be no very great excitement, we may try mild tonics;—the mildest form of iron, for instance; but during the greater period of the disease, antiphlogistic measures, mildly carried on, constitute a preferable mode of treatment.

## SECTION II.—ENLARGEMENT OF THE MESENTERIC GLANDS.

If, along with chronic peritonitis, the mesenteric glands are enlarged,—or if, indeed, they are enlarged *without* that affection,—we may, or may not, have a tumour. The mesenteric glands are frequently much diseased, without producing a tumour; yet they are sometimes so diseased, that there is a general hardening of the abdomen. When peritonitis exists, in the greater number of cases we can only infer disease of the mesenteric glands from the scrofulous look of the patient, from his wasting away, and from there being something more than what chronic inflammation of the peritonæum can produce. When there is tumefaction from disease of the mesenteric glands, frequently a great deal of it is from flatulence; so that if we strike with the fingers, we have a very considerable sound. Sometimes tubercular matter is deposited in the peritonæum itself; so that, besides chronic peritonitis, we have scrofula of the peritonæum. It is by no means easy to make out the exact nature of such a case as this. It is pretty clear that there is peritonitis, and that there is likewise scrofula; but whether there are tumours or not, or whether the disease affects the mesenteric glands, or the peritonæum itself, is not always an easy matter to decide; nor is it of any consequence.

*Symptoms.*—Occasionally the mesenteric glands acquire a very large size; and, before that, there is a great sense of dragging in some particular direction. In those cases which are very bad, and where there is scrofula in the abdomen at the same time, there is great emaciation, together with sallowness of the complexion,—sometimes a sort of marble-white; and a hectic flush on the cheek,—at any rate, at certain parts of the day. The eyes look clear and glazed. Occasionally, in the course of the day, there is deep lancinating pain in some parts of the abdomen. The stools are generally abundant;—foul, frothy, and imperfectly tinged with bile. Occasionally there is great disturbance of the stomach; so that patients complain of a burning sensation in that organ. The lips frequently swell; are of a deep red colour; and crack, from ulceration in the corners. There is also feverishness. Although the pulse is constantly quick, yet there are exacerbations. When the patient does not sweat on falling asleep, the skin is frequently quite dry. The emaciation, in these cases, is often extreme; and the ends of the fingers become enlarged;—exactly as in phthisis.

These are the general symptoms of scrofula of the mesenteric glands, and of peritonitis. The symptoms are always much more severe, and the emaciation is greater, than in simple inflammation of the peritonæum; but still it is often difficult to say whether the latter affection exists alone, or whether the two complaints are united. It is only by finding that the disease will not give way to common antiphlogistic measures, that we begin to suspect, at last, that there must be something more than inflammation of the peritonæum. Occasionally it is not so much the *mesenteric*, as the *lymphatic* glands that are diseased;—particularly the glands of the loins.

*Most Frequent in Children.*—All these affections occur more frequently in children, than in adults; but occasionally they occur in the latter.

*Effects of Mesenteric Disease.*—If the mass of tubercular substance be very great, it may produce peculiar effects, by its pressure on various parts. From pressure on the ureters, we may have more or less suppression of urine; by pressure on the gall-ducts, we may have jaundice; and by pressure on the pylorus, we may have vomiting. Some have supposed, that when the mesenteric glands are enlarged, the emaciation is the consequence of the chyle being interrupted in its

course; but even if the chyle be not obstructed, the serofulous disease is sufficient to account for the wasting of the body. In fact, some experimenters say, that they have always found an injection pass freely through the absorbent glands; although they were enlarged in various degrees. Many have asserted this.

*Morbid Appearances.*—The havoc which is found in these cases, is sometimes dreadful. The whole of the intestines may be glued together. Sometimes there is ulceration of the peritonæum itself;—the intestines within being sound. Occasionally the ulceration makes the peritonæum quite thin. It even ulcerates through; and then we find ulceration of the intestines, and chronic inflammation of the mucous membrane of the intestines, and of the lacteal glands. Frequently the lumbar and dorsal glands, are all in a state of enlargement and suppuration; so that there is extreme suffering, and the most decided hectic before death; and, after it, we certainly have the most frightful spectacle that can be seen in morbid anatomy. This is entirely a serofulous affection.

*Treatment.*—When the disease does not give way to ordinary treatment,—to the application of moisture, warmth, and steady purging; or moderate purging, local bleeding, and similar remedies, we may suspect there is something more than chronic inflammation of the peritonæum; and, on meeting with such a case as this, it may be right to exhibit iodine in its various forms; and if we can discover a tumour in any part, or any general hardness of the abdomen,—so as to make it probable that the mesenteric glands are enlarged,—it may be given from the first. We should also rub in iodine, in the form of hydriodate of potass, if the patient can bear it; but there is frequently too much pain for it to be borne at all. The hydriodate of potass will often be borne, when the iodine itself cannot. But these are very unsatisfactory cases to treat; and frequently all that we can do, is to send people from the unhealthy situation in which they may reside, to the fresh air.

### SECTION III.—ASCITES.

Sometimes, although the chronic inflammation of the peritonæum is very inconsiderable, yet the effusion is exceedingly great. Sometimes, indeed, there is scarcely any mark of inflammation to be found; but we have a structural change of the peritonæum, and a great deposition of water. The peritonæum becomes thick, and assumes a satin-whiteness. In fact, it looks like a piece of satin-ribbon; so that it may be doubted whether this state is inflammation; but it is of an inflammatory nature. When this effusion is very considerable, we call the disease “ascites” (from *ασχος*, *a large abdomen*).

*Causes.*—When ascites is not the result of acute or decided inflammation, we find (in most cases) that there are marks of structural change; and some ascribe it to disease of the liver; so frequently is that organ affected at the same time. Where, however, the peritonæum is diseased, the portion covering the liver is very thick, quite white, and opaque: and I believe that ascites does not arise from disease of the liver, but from a structural change in the peritonæum itself. Some ascribe it to an obstruction in the liver or spleen. An obstruction may exist in those organs; but if the ascites arise from that source, it is very odd that we do not find a varicose state of all the veins, effusion into the intestines, and changes of that description. I have seldom opened a case of ascites, in which the liver was not diseased, in some part or other.

*Symptoms.*—Dropsy of the peritonæum is characterized by a fluctuating and elastic equable tumefaction of the abdomen. At first it only inconveniences the patient when he is sitting upright, and fluctuation is discovered only at a certain point; but, as the disease extends, the tumefaction becomes universal. The best mode of discovering the fluctuation, is to place the hand against one part of the abdomen, and then to give a gentle tap with the fingers on another. Occasionally the integuments, or the peritonæum, are very much thickened; and it is then necessary to give a good *sharp* tap; but, for the most part, a very *gentle* tap will lead

us to feel the fluctuation. Sometimes the fluctuation does not exist throughout; and occasionally the peritonæum differs in thickness at various parts; so that it is necessary to tap from above downwards, and in various ways. There is in general, as in most other dropsies, very little urine; but however much the abdomen may be distended, there is generally little dyspnoea, so long as the chest remains free. So long as there is not disease of the heart, or pleuritis, or bronchitis, it is surprising how well patients will breathe with a very large abdomen. The tumefaction begins, of course, in the lower part; and gradually ascends, till the whole abdomen is distended.

*Progress of the Disease.*—This affection, after a time, is followed by œdema of the legs; but sometimes the latter takes place first; and the ascites is nothing more than the result of a general tendency of the cellular membrane of the body, and serous membranes, to secrete fluid. But where there is not this general disposition to dropsy, and its occurrence in the abdomen is a local disease, swelling of the legs frequently does not take place for a considerable time. Shakspeare describes Falstaff as having a *decrease* of the *legs*, and an *increase* of the *belly*.<sup>a</sup>

*Prognosis.*—If the disease be the mere effect of acute inflammation, subduing that, and the dropsy will cease; but when it does not arise from that source, or is not the result of any discoverable inflammation, the prognosis is generally bad; and more especially if we can discover disease of any of the abdominal viscera.

*Characters of the Fluid.*—The fluid that is found after death, or which we let out, is generally yellow and glutinous; and the longer the disease lasts, and the more frequently the patient is attacked, the darker it generally becomes, and the worse becomes the case itself; because the peritonæum falls more or less into disease, and perhaps becomes quite soft.

*Treatment.*—The treatment of the disease must depend, in the first place, on the fact of there being any inflammation or not. If we discover inflammation, generally speaking, we have merely to treat that; but if there is no inflammation, but simply a swelling of the abdomen, we may frequently get rid of it by purging the patient briskly with elaterium, or any other hydragogue purgative;—such as jalap or cream of tartar.

*Elaterium.*—Elaterium is better than any other purgative;<sup>b</sup> and patients will take it for a considerable time, every day, or every other day. It is necessary, however, to begin the dose very carefully; for one person will not bear above a quarter of a grain, whereas I have given others five or six grains. Much depends upon the preparation; for nothing is more adulterated than elaterium. Some houses prepare it very carefully, and some very badly; but when we have a tolerably good preparation, we should give a quarter of a grain, and ascertain how far the person to whom it is given can bear it. If we give a grain at first, it may produce such violent vomiting and purging, as to cause great distress. Some patients will bear the dose increased to five grains; but generally the average quantity is from half a grain to a grain and a half. While exhibiting this every day, or every other day, it will be good practice to support the patient with wine; so that while we drain him well, we make him some sort of amends for it. It is astonishing, how much fluid may be got away; and while there is no rule for the dose, yet the object is to discharge as much liquid from the alimentary canal as possible,—according to the patient's strength.

*Iodine and Mercury.*—Purgatives are certainly among the best means we can employ. Neither leeches nor blisters do much good. If there is organic disease of any sort, we may give mercury, iodine, and remedies of that description; but frequently, with all these, we do not succeed; and are obliged to tap the patient.

<sup>a</sup> *Sir John Falstaff.* You that are old, consider not the capacities of us that are young.  
*Lord Chief Justice.* Do you set down your name in the scroll of youth, that are written down "old," with all the characters of age? Have you not a moist eye, a dry hand, a yellow cheek, a white beard, a decreasing leg, an increasing belly? "*King Henry the Fourth*;" Act 1; Scene 2.

<sup>b</sup> See Page 172.

I do not know that there is any harm in tapping early. On the contrary, it may be of great use in preventing the parts from becoming so stretched, that they will not contract again. Others have thought the same; but I have not a series of cases treated on each plan. It is a fact with respect to dropsy of the ovaries, that the more we tap, the more harm we do. The sooner we tap the patient, the sooner must she be tapped again. In ovarian dropsy, the greater the length of time we can postpone the operation, the longer we may still put it off; but this is not the case in dropsy of the peritonæum.

*Diuretics.*—If we choose to treat the disease with diuretics,—which is frequently a good practice,—squills, digitalis, and mercury, answer exceedingly well. This is not so certain a practice as treating the case by hydragogues, which are also diuretics; for if we adopt it, we frequently find that the kidneys will not act; and yet, on tapping the patient, they will act directly. It is common, when the abdomen is in a state of great distension, for the kidneys to refuse to secrete; but if we take off the tension, the patient will make a great quantity of water. We may observe this, whether patients are taking diuretics or not. It is always a useful plan, when the water is diminishing, to have the abdomen well bandaged; or to have a thin belt, producing equal pressure throughout; which is apparently of very great use.

*Precautions in Tapping.*—As to the mode of operating, and the part to be selected for the purpose, I need not say any thing on that subject. It would be well, however, before proposing the operation to a surgeon, carefully to ascertain whether the disease exists;—to ascertain, not merely that there is fluctuation, but fluctuation from a collection of water in the peritonæum; because the urinary bladder will occasionally become enormously distended. I have seen it so distended, that the person has been supposed to have ascites; but on drawing off the urine, the ascites entirely disappeared. This disease sometimes coexists with pregnancy; and pregnant women have been tapped for ascites with success. Sometimes it will coexist with a diseased ovary. I have known instances where the ovary was as large as a child's head; and where, in addition to that, there was ascites all around it.

*Tympanites.*—Occasionally air is collected in the peritonæum; and this is one of the diseases called “tympanites.” Sometimes the intestines are exceedingly distended with air: so that the person becomes very large, and the tumour gives rise to a sound like a drum; whence its name (from *τυμπανον*, a drum). But, properly speaking, tympanites is a great collection of air in the peritonæum; and I believe this usually takes place from an aperture existing in the intestines;—so that air escapes.

#### SECTION IV.—ORGANIC DISEASES OF THE PERITONÆUM.

The peritonæum is subject to some other diseases;—such as to become cartilaginous, or even bony; and to have hydatids, or scirrhus, or fatty tumours deposited in it. The same remark applies to the omentum.

*Diseases of the Abdominal Glands.*—The lymphatic glands within the abdomen, besides being subject to the disease I have mentioned (scrofula)<sup>a</sup>, are sometimes found after death to have become indurated,—almost changed to cartilage; and to have suppurated, independently of all scrofula;—to have pus collected in them, in small quantities, or in drops. These glands are also subject to melanosis, to scirrhus, and to the formation of earthy concretions; and so likewise are the *mesenteric* glands; but we cannot make out the real nature of the affection, till after death. When the inner surface of the intestines is much diseased, we are almost sure to find the mesenteric glands also affected. When there is scirrhus, or cancer of the intestines, all the neighbouring glands, lacteals, and absorbents,

<sup>a</sup> See Page 876.

are commonly enlarged, and labouring under the same disease. But we cannot discover this during life; unless, by chance, some particular tumour is produced.

*Cysts in the Abdomen.*—The peritonæum (or, at least, the sub-peritoneal cellular membrane) is likewise subject to the formation of cysts. Occasionally cysts are found in other organs,—projecting into the peritonæum. Sometimes the ovaries will become dropsical;—cysts being formed in them. Occasionally large cysts are attached to the concave surface of the liver,—sometimes to the centre, and in other instances to the side. Besides general dropsy of the peritonæum, therefore, we frequently have large serous cysts. In these cases the tumour is not general, but local;—does not occur at the lower part particularly, but may take place anywhere in the abdominal region. It usually occurs at one side, in the first instance, and arises from one of the ovaria. The fluctuation is local. Though the tumour most frequently arises from the ovaria, yet I have seen a large cyst at the epigastrium, attached to the liver. Now and then there are small cysts attached to the spleen; and, at last, the tumour will become so excessively large, that it is impossible to say whether there is ascites or not. The whole peritonæum will become filled. So again, with respect to the ovaries, we may not be able to say whether there is ovarian dropsy or not.

*Quantity of Fluid in Ovarian Dropsy.*—It is surprising to see how much water is sometimes collected, in cases of ovarian dropsy. I once saw an old woman, who had had the disease many years, and never would be tapped. At last, a certain quantity of water was let out; and we found that it amounted to eighty-four pints. The diaphragm had been pushed up to the fourth rib; the chest was exceedingly small; but the size of the abdomen was immense. That, however, was nothing to what other people have seen. M. Chevalier says, that he once saw one hundred and thirty-six pints removed;—all of which must have existed at once. The case is mentioned in the third volume of the “*Medico-Chirurgical Transactions*.”<sup>a</sup> It was drawn off at three or four times. The health, in these instances, is not affected, as it is in dropsy of the peritonæum; so that a woman at Paris lived to be tapped three hundred times. Another woman was tapped one hundred and fifty-four times. In the course of that period she had three children; and was tapped two or three times during each pregnancy; so that she lost no time, but went on bearing children and water too. At least twenty pints were removed at each time; and she was tapped, at various periods, during twenty years. There is another case recorded, where six thousand six hundred and thirty-one pints were taken away. It was not all removed at once; but was drawn off at eighty operations, performed in the course of twenty-five years;—so long do women sometimes live in this affection. I suppose they kept a very accurate account. In one year this woman had four hundred and ninety-five pints taken away. The case is mentioned by Dr. Mortimer, in the “*Philosophical Transactions*.” There is an account, by a celebrated French surgeon, of a case where four hundred and twenty-seven pints were taken away in ten months. A case is mentioned by Mr. Carruthers, in his work on inflammation, where a woman was tapped nineteen times in three years. A German author mentions an instance, where a person was tapped one hundred and forty-three times. A few years ago, an advertisement appeared of a woman who wished people to go and see her (and pay for it, I presume); and who stated that she had been tapped one hundred and twelve times, and had had two thousand eight hundred and eighty-eight pints taken away from her. She came from Chepstow. I had not time to see her; but she had the certificate of a medical man;—stating that he had performed one hundred and twelve operations, and had removed two thousand eight hundred and eighty-eight pints. Whether the case is true or not, is of little consequence; because, without doubt, great quantities have been taken away. It is no matter whether exactly six thousand six hundred and thirty-one pints were drawn off,—as mentioned in one of the foregoing cases. Five thousand will do very well to

illustrate the fact, that people in this disease will live very long, suffer an immense secretion of water, and bear the operation of tapping an extraordinary number of times.

*Characters of the Fluid.*—The fluid, in ovarian dropsy, is often exceedingly greasy; so that a quantity of iridescent, or at least whitish shining matter is seen on the surface; and, if rubbed in the fingers, will form an unctuous mass. I have collected it; and found that it would melt and burn, like any waxy matter. It emits a bright flame, and is insoluble in water. Dr. Bostock mentions, in the fifteenth volume of the “*Medico-Chirurgical Transactions*,”<sup>a</sup> that in a case of very old hydrocele, he found the serum mixed with a portion of this unctuous substance. He conceives it to result from a change which the fluid has undergone, subsequently to its original deposition. In order, however, for that to have taken place, it must have been of very long standing. He found it to be analogous to that greasy matter which is called “*adipocire*.” He terms it “*albumino-serous matter*,” and says it is distinct from cholestérine. It is not the same as that which is found in the liver, the urine, and certain biliary calculi; though it is of an analogous nature. Something like this has sometimes been found in the thyroid gland, and in the fluid of various tumours.

*Tapping in Ovarian Dropsy.*—In dropsy of the ovary, I should certainly make it a rule to defer the operation of tapping as long as possible: first, for the reason I mentioned before;<sup>b</sup>—that it is a fact, (and also a common opinion among the vulgar,) that when we have once tapped a patient, she soon requires to be tapped again; and, secondly, because, although in an early period of the disease there may be many cysts, yet in general they ultimately open into each other; so that we have only one great cavity. Hence, in tapping early, we most probably draw off only a portion of the fluid by the operation;—the cysts being distinct, and not freely in communication with each other.

*Iodine and Mercury.*—In these cases, the only remedies that (so far as I am aware) are of any use, are iodine, and sometimes mercury. Indeed, the best practice, in cases of encysted dropsy of the ovary, is to support the patient’s strength; to put off tapping as long as possible; and to give no medicine whatever, except it be iodine. It is in vain to attempt to excite absorption by diuretics; and by purging we only nauseate the stomach, and take away the appetite. I have seen cases of encysted dropsy of other parts of the abdomen yield, apparently, to the free exhibition of iodine internally, and its application externally; and I have seen it succeed partially in dropsy of the ovary. I have fancied that the power of this remedy has been increased, in a trifling degree, by combining it with mercury.

Very often, when an ovary is enlarged, there is no fluctuation to be found for a long time. The walls are solid;—solid substance is deposited; and it is not till the fluid has accumulated to a considerable extent, that we can discover fluctuation. Encysted tumours of the abdomen, especially in young women, are partly solid and partly fluid; and occasionally, on squeezing the part, we find small movable tumours, having portions of cartilage sometimes deposited in them. In some cases, they contain hydatids. I had a case, in 1828, in which there was a tumour of this description; and which I concluded was a tumour of the ovary. Fluctuation was not very apparent; but still there was fluctuation. I was giving this patient considerable doses of calomel,—on account of there being a large quantity of solid substance, apparently of very great hardness,—when she was seized with violent vomiting and purging, accompanied by intense pain. Whether the vomiting and purging arose from the calomel, I will not say; but she had been taking it for some little time; for I fancied there might be solid matter, as well as a collection of fluid. In the course of one night, the tumour entirely disappeared; after having resisted every other means for some months. It might be that the tumour, in this case, had burst into the peritonæum; and that the fluid had been quickly sucked up by the absorbents of the peritonæum, and as quickly secreted by the vessels of the kidney.

<sup>a</sup> See Page 154.

<sup>b</sup> See Page 879.

Or it might be, that violent purging being set up, a great discharge took place from the intestines; and the absorbents went to work, and reduced the tumour. However that may have been, the fluid re-accumulated; and the tumour became as large as ever;—and that after no very great lapse of time. One would hardly suppose, that the absorbents within the tumour were sufficient to produce such rapid absorption. It is more likely that the tumour had burst at some part. We are told, that occasionally the fluid has been discharged by the vagina;—that tumours of this kind have ruptured into the peritonæum;—that the fimbriated extremities of the fallopian tubes have set to work, and have poured the fluid into the uterus; and that thus it has been discharged through the vagina. There are several cases on record, of women falling down with ovarian dropsy; and beginning, very soon, to discharge a quantity of water from the vagina; which discharge has continued till the swelling has disappeared. It is sometimes difficult, in these cases, to know whether the water comes from the vagina or the urethra. If it come from the former, we must suppose that the tumour has ruptured, and that the fallopian tubes have pumped up the fluid; whereas, if it come from the latter, we must suppose that the vessels of the peritonæum have sucked it up, and that it has then been re-secreted by the kidneys.

*Dropsy of the Fallopian Tubes.*—Occasionally we may have what perhaps may be, and sometimes is, called “encysted dropsy of the abdomen;”—arising from a fallopian tube being closed at each end, and a great quantity of fluid being accumulated within.

## CHAPTER II.

### DISEASES OF THE PANCREAS.

*Affections to which it is liable.*—The diseases of the pancreas with which we have to do, are all structural. We do not know whether there is any *functional* disease to which it is liable; unless it be the formation of stone. We do not know what office the pancreas performs, either when it is *out* of order, or when it is *in* order. We know nothing about it. No one would refer a symptom that he has, to mere functional disease of the pancreas. It is very seldom that it is the subject of *acute* inflammation. I never met with such a case. But now and then it is diseased in a *chronic* manner; especially when there is disease of a neighbouring organ.

The most common affection of this organ, is either common induration, or that particular disease called “scirrhus.” Dr. Baillie says that he once saw an abscess in it; and, now and then, common ulceration is seen. It is said to be sometimes ossified; and sometimes to have hydatids. Sometimes it is wasted, and sometimes it is very large; but, for the most part, this organ is not found diseased in dead bodies; and whenever it is, I believe the disease has evidently been of a chronic form.

*Diagnosis.*—The diagnosis of structural disease of the pancreas, must be exceedingly difficult. Dr. Pemberton, in his work on Diseases of the Abdominal Viscera,<sup>a</sup> says there is deep-seated pain in the epigastric region; especially if one hand be placed at the back, and the other on the stomach. However, the pain may not be felt; or we may have pain there from an affection of the stomach; so that very little, I conceive, is to be learned from that. He says there is more or less sick-

<sup>a</sup> “Morbidity Anatomy,” Chapter 12; Section 1.

<sup>b</sup> “Practical Treatise on Various Diseases of the Abdominal Viscera. By Christopher Robert Pemberton, M.D.” Chapter 4. (Third Edition; Page 63.)

ness, gastrodynia, and emaciation; but I should think that, in general, it must be a mere guess,—even if the person is right,—when he pronounces that the patient is labouring under disease of the pancreas.

*Pancreatic Calculi.*—Now and then a calculus exists in the pancreatic ducts. I opened a patient, not long ago; and was surprised to find calculi in the pancreatic duct. I forget what was the matter with him. The appearance was exactly the same as that given in one of Dr. Baillie's engravings. We know that the duct of the pancreas runs the whole length of the organ; that it is fine at one end, and large at the other; and that the ramifications of it, altogether, look like a feather. I believe these calculi are always homogeneous; and there must have been at least a hundred in the case that I opened. The duct represented in Dr. Baillie's engraving, had attained an enormous size. Pancreatic calculi were analyzed by Dr. Wollaston; and were found to consist of carbonate of lime in the human subject, and phosphate of lime in the ox. But these topics are more the subject of Morbid Anatomy, than of the Practice of Medicine.

---

## CHAPTER III.

### DISEASES OF THE SPLEEN.

THE next disease of which I will speak, is an affection of the spleen. We know nothing of disordered *function* of the spleen, any more than of disordered function of the *pancreas*; but structural diseases of the organ, and inflammation of it, are sometimes exceedingly evident. Like the pancreas, it is very rarely affected with *acute* inflammation, or with suppuration. Now and then, in peritonitis, that portion of the membrane covering the spleen is inflamed; but the substance of the spleen is seldom affected in that way.

*Chronic Splenitis.*—When it is the subject of *chronic* inflammation, there is pain in the region of the spleen;—pain far back on the left side, higher than the kidney; but there are no symptoms of chronic inflammation of the kidney;—such as a retraction of the testicle, pain down the thigh, pain in the testicle, and an unnatural desire to make water. There is an absence of the symptoms of inflammation of the kidney.

*Hypertrophy of the Spleen.*—It is not uncommon to see the spleen enlarged after ague. I formerly stated<sup>a</sup> that this disease is called “ague-cake” by the common people; but technically it is termed “hypertrophy of the spleen.” When it is in this state it is generally harder than natural. The size that the spleen will attain is very considerable. I have seen it reaching the pelvis; and extending from the navel towards the other side. We may easily distinguish between an enlargement of this organ, and an enlargement of the liver, by this circumstance;—that, on applying the fingers, we find the edge is vertical; whereas, in enlargement of the liver, the edge of the tumour is horizontal. The hypertrophied spleen has sometimes weighed twelve pounds. Hoffmann mentions finding one that weighed fifteen pounds; and Morgagni, on second-hand information, mentions a case where the tumour weighed thirty-five pounds.

*Causes.*—This disease will occur in children, and I have frequently seen it in infants. It generally arises after ague, or after the patient has been exposed to malaria. I met with a singular instance of this enlargement, some years ago. A woman had two children; and she herself had had ague, but they never had. I rather think she had lived in an aguish part of the country, before the children were born. One of them had enlargement and induration of the spleen, and died. After a time,

the same disease began in another child; and I believe it is going on now. I have no doubt but that it will kill it. On opening the body of the first, we found the spleen enlarged, and very hard; but, in other respects, the structure appeared healthy. There was no unnatural appearance in it.

*Constitutional Effects.*—Patients, in this disease, are generally very pale. The blood is not proper in *quality*, if it is in *quantity*;—it is deficient in fibrin, and likewise in red particles. The wasting of the body is not in proportion to the paleness. The patient's bulk remains pretty good, for a long time; although he will become blanched,—in a state of anæmia. Now and then there is a little ascites. The peritonæum covering the spleen becomes affected, like the rest of the membrane; and produces a larger secretion than before. The diagnosis is very easy, long before the spleen has attained to a large size.

*Treatment of Hypertrophy.*—With regard to the *treatment*, it would be merely that for any chronic inflammation, or induration. I believe that, if the tumour attains any very great size, nothing can be done; but I have diminished it by the administration of iodine, externally and internally. I have successfully treated many cases in this way; but I have seen others in which treatment of this description failed. If there be pain on pressure, local bleeding, mercury, and the common remedies for inflammation, will be proper. Where the disease has arisen from malaria, it would certainly be well to give the sulphate of quinine; for I have seen improvement take place where the constitution has suffered from malaria; and I have also seen enlargement of the liver much diminished, and give way, with very little other trouble. If, therefore, there had been any exposure to malaria, I should give the remedies for ague; but iodine has frequently, I know, a considerable effect in diminishing diseases of this description. Sometimes there is no pain whatever; and there, of course, we should not think of applying leeches, or bleeding the patient. But if there be pain on pressure, local bleeding ought to be resorted to, in proportion to the general affection.

*Induration and Softening of the Spleen.*—Sometimes, without any enlargement, we find the spleen exceedingly *hard*,—cutting exactly like liver; and sometimes, on the other hand, it will become exceedingly *soft*. Very often where, during life, we could discover no particular ailment referable to the abdomen, the spleen is soft. If it be not preternaturally hardened, we may, by working it up in our hand, bring it to the consistence of currant-jam; but in various diseases we find that the spleen, on being cut, is soft.

*Congestion of the Spleen.*—The spleen suffers a great accumulation of blood, when there is any obstruction in the organs of respiration. It is supposed by some, that the size of the spleen may depend very much upon the mode in which patients die. If they die after long-continued dyspnoea, we may find the spleen large; although, during life, it was not so enlarged.

*Tubercles of the Spleen.*—Tubercles, of various kinds, are found in the spleen; and I met with a singular instance of a large number of vessels in the spleen in a state of ossification.

*Pancreatic Calculi, &c.*—Calculi have been found in the spleen; but diseases of this organ are not very apparent, unless the organ itself becomes enlarged. It is said that people can do as well *without* this organ, as *with* it; and, since the time of Galen, persons have amused themselves with cutting out the spleens of the lower animals; and have said that they perceived no difference afterwards. It is said that the spleen, as well as the pancreas, has been absent congenitally; but such things must be exceedingly rare.

## CHAPTER IV.

## DISEASES OF THE LIVER.

## SECTION I.—HEPATITIS.

WE will now proceed to consider the diseases of an organ far more important than the pancreas or spleen;—namely, the liver. It is very subject both to acute and to chronic inflammation.

*Symptoms of Acute Hepatitis.*—When the liver labours under *acute* inflammation to any considerable amount, the symptoms are pyrexia and constant pain, chiefly in the right hypochondrium. The greater part of the liver is on the right side; and therefore we have the pain chiefly there. There is likewise a sense of tension, or weight. It is said, that if the *surface* of the liver suffer, there is mere tension; whereas, if the *substance* be affected, then a weight is experienced; or if it be the peritonæal coat which is inflamed, then we have a greater degree of pain on pressure, and pain of a sharp character. The pulse is said to vary accordingly as we have inflammation of the peritonæal coat, or inflammation of the substance; but we cannot depend much upon that. We have different kinds of pulses, in various circumstances. The pain extends up to the scapula, goes through to the back, and very frequently to the right shoulder. The patient lies best on the *right* side; because, if he lie on the *left*, the whole mass of the liver (situated as it is chiefly on the *right* side) drags towards the *left*, and all the parts are put on the stretch. We find, in disease of the *heart*, that he lies best on the right side; and this is also the case in disease of the *liver*; but the situation of the uneasiness makes the difference between the two diseases very remarkable. There is difficulty of breathing, and an affection of the chest, in disease of the liver; but not so great as in disease of the *heart*. The difficulty of breathing arises from the motion of the liver, in respiration, in accordance with the ascent and descent of the diaphragm. There is likewise, from the proximity of the liver to the diaphragm, a dry cough; and if we have any doubt about the situation of the pain,—whether it is just on one side the diaphragm, or on the other,—we have only to apply the stethoscope. If it be disease of the *liver*, there is no alteration of the sounds; whereas, in an affection of the *chest*, we find the various signs which I mentioned before.<sup>a</sup> From the proximity of the liver to the stomach, there is very frequently nausea and vomiting. Very often there is a little jaundice; and sometimes *complete* jaundice.

*Termination in Suppuration.*—This acute inflammation frequently terminates in resolution; and sometimes in suppuration. The latter circumstance is rare in this country; but in hot climates it is very common. Occasionally,—as I mentioned when speaking of suppuration of the brain,<sup>b</sup>—the pus is secreted in small drops throughout the organ; but in other cases it forms one immense abscess; and sometimes both circumstances occur. The quantity of matter which will be collected in this way, is sometimes enormous. There are various ways by which nature gets rid of this pus. Occasionally an adhesion forms between the two parts of the peritonæum,—the loose and the visceral; and the matter points externally. Sometimes an adhesion takes place to the stomach; sometimes to the intestines; and I think the matter more frequently finds an outlet in that way, than in any other. Sometimes nature does not succeed in forming adhesions, and then the matter is poured into the peritonæum. Now and then an occurrence takes place less favourable than the discharge of the pus, into the stomach and intestines;—

<sup>a</sup> See Pages 707 to 715.

<sup>b</sup> See Page 438.

adhesions take place to the diaphragm; and the matter is discharged through the air-passages. We have cases on record, in which the pus has discharged itself into the gall-bladder; and cases still more rare, in which it has presented itself, not at the *front*, or at the *side*, but at the *back*. Cases of this description have been mistaken for lumbar abscess. Occasionally the matter has been discharged with the urine; and there is one case upon record, in which an abscess emptied itself into the "vein cava;" and death was the consequence. Sometimes the abscess does not discharge itself at all, but there it remains; and patients have died with a large abscess in the liver;—the existence of which was not known before. If the matter be disposed to discharge itself externally, it is evident enough; if it discharge itself into the stomach, we have vomiting of matter; if into the intestines, we have a quantity of matter in the stools; and if it discharge itself by the air-passages, you have cough, and many of the other signs of phthisis.

*Terminates in Chronic Hepatitis.*—But more frequently than otherwise, perhaps, the *acute* disease subsides into the *chronic* form. If the inflammation be situated on the surface, we shall have great chronic inflammation;—there will be great pain, especially on pressure, and (in all probability) ascites,—from the peritonæum being affected. If the substance only is diseased and the peritonæum escapes, we have merely a dull heavy pain there; and very frequently no ascites at all. Of course chronic inflammation of the *substance*, and of the *surface* of the liver may be conjoined;—the same as in the *acute* form; and the former, as well as the latter, will produce an abscess, and be followed by all the structural diseases to which the part is subject.

*Common in Fevers of Hot Climates.*—The *acute* form of the disease is very common in all the fevers of hot climates; and hepatitis is continually united with all other inflammations of the abdomen;—with enteritis, peritonitis, gastritis, and all the other inflammations of that region. The *chronic* form is very often united with dysentery. It is very common for a person to have chronic *dysentery*, and chronic *hepatitis* at the same time.

*Causes.*—The *causes* of hepatitis, whether acute or chronic, are the common causes of inflammation;—getting wet, exposure to cold, and other similar occurrences. It appears to be much predisposed to by continued heat; the disease, at least, is very common in hot climates. It is said that long-continued heat alone induces pure hepatitis; whereas, if the long-continued heat be united with the cause of fever,—such as malaria and other things,—then we have a combination of hepatitis with various fevers.

*Diagnosis.*—As to the *diagnosis*, the disease is easily distinguished from inflammation of the chest, in the way I have mentioned;—by the absence of all auscultatory signs; by the situation of the pain; and by there being nausea and vomiting. It is distinguished from gastritis by the situation of the pain, which is much to the right side; while, in gastritis, it is in the epigastrium, and more to the *left* side,—from the stomach being to the left of the epigastrium. We may have symptoms at the epigastrium in hepatitis; but we have also considerable pain on the right side. It is distinguished from peritonitis by the local nature of the pain; for, in peritonitis, there is inflammation at other parts of the abdomen.

*Morbid Appearances.*—On examining the liver after it has been in a state of common inflammation, we find that it is the convex portion of the liver that is generally inflamed. There may be red points, lymph, and turbid serum upon it; and the peritonæum may perhaps be thicker than it should be. In chronic inflammation, we find adhesions; and the bands are very strong. Sometimes there are white patches on the surface of the liver; and the peritonæum becomes white, opaque, and soft. If the substance have been inflamed, there is usually a general redness; and the size of the liver is increased,—from the quantity of blood it contains. Sometimes the redness is only partial; and then the red plates, mingled with the parts naturally pale, give it a mottled appearance. In cutting the liver, generally a large quantity of blood flows out; and we must remember that, without inflammation, the liver frequently suffers a great congestion of blood. In the dis-

ease called "purpura," there is great congestion of blood in the liver. After asphyxia, chronic bronchitis, all diseases of the heart, and all obstructions to the course of the blood through the heart or lungs, we find the liver in a great state of turgescence; so that, on cutting it, the blood pours forth, and the vessels look like sinuses. In infants who have been asphyxiated at birth, the congestion of blood in the liver is occasionally so great at the part under the peritoneal coat, that sometimes it will burst through it into the abdomen. Sometimes, in inflammation of the liver, there is hæmorrhage into the substance of the organ; and sometimes the blood will *rupture* the substance of the organ. I presume there must have been some degree of softness of it previously. We may find a great mass of blood, or several little collections of it; sometimes it is coagulated, and sometimes not; occasionally we may find it in the vessels, and sometimes not;—accordingly as it has oozed from one, or from several.

*Treatment.*—We have now to consider the *treatment* of acute and chronic hepatitis; and this may be dismissed in a very few words. It is the simple common treatment of inflammation; and, for the most part, it is very successful. We have only to make our diagnosis;—to ascertain that it is disease of the liver, acute or chronic; and to treat it accordingly. It was once supposed (as we find mentioned in works published twenty or thirty years ago), that mercury ought not to be given in *acute* inflammation of the liver, because it stimulated the organ; but that it was proper in the *chronic* form. The truth is, however, that both forms require the same treatment. The terms "*acute*" and "*chronic*" refer merely to the *duration* of the disease; and there is no difference between them, except that the symptoms are less urgent at one time than at the other; and whatever is good in the one, is beneficial in the other in a less degree. But, independently of that consideration, I do not know that mercury has any extraordinary power in stimulating the liver, in the way that has been supposed. It was thought it would give a bilious tendency, when there was not one; and it is possible that mercury may produce bilious evacuations, when it is long continued; but I am sure that mercury, pushed on to ptyalism, is just as useful in active hepatitis, as in any other active inflammation. I do not know that it will do any good by its specific action on the liver; but it will by its general tendency to subdue active inflammation. Purgatives are particularly useful in inflammation of the liver;—much more so than in inflammation of the chest; because they act as local means, and prevent a great quantity of blood from going into the "*vena portæ*;" and therefore less gets into the liver.

*Treatment of the Chronic Form.*—The *chronic* inflammation requires the same treatment as the *acute*, only carried on less violently,—carried on chronically;—not doing all we have to do in a day or two; but carrying on our measures for some weeks, or even months. The moderate exhibition of mercury—not to produce a rapid ptyalism, but so as to keep up a gentle affection of the mouth—is useful. Long-continued purging is very beneficial in chronic disease of the liver; and hence the Cheltenham waters do great good in this affection, by draining the abdomen generally. Some have conceived that acids are useful as tonics; and the nitric and muriatic acids were very famous some time ago; but I do not know that there is any particular use in them. I have always succeeded in treating chronic inflammation of the liver, by the same means that I employ in any other inflammation;—more or less loss of blood, general or local, and the moderate exhibition of mercury. I have never found it necessary to make any difference between treating inflammation of the liver, and inflammation in any other part. Some have thought that dandelion does good; but I have never seen its virtues in affections of this kind.

*Treatment of the Suppurative Stage.*—As to the suppuration which sometimes occurs, that requires to be treated on common principles. If the abscess point to the skin, of course a knife may be applied, and the matter let out;—just as in any other abscess: only that it might be dangerous to let out a great quantity at once. It should be done gradually, in order that the part may slowly contract. If the discharge take place inwardly through the lungs, or the intestines, we have only to

lessen the irritation by narcotics,—as in other cases; and this will also be required on opening the abscess.

## SECTION II.—STRUCTURAL DISEASE OF THE LIVER.

*Symptoms.*—Many diseases of the liver are called “chronic hepatitis.” The liver is subject to a vast number of structural diseases; and these pass as chronic hepatitis. Indeed, it is very often impossible to make the distinction. At the outset, there is pain on the right side, pain at the shoulder, perhaps a little jaundice, tenderness in the region of the liver, feverishness, and wasting; and we may say that the patient is labouring under chronic hepatitis. We treat him accordingly; but without success. On the contrary, the disease obstinately remains; and at last, perhaps, the liver becomes much thickened, and very much enlarged. Sometimes it is enlarged and hardened, from the very first;—simply as the result of inflammation; and sometimes it may be subdued by the common remedies of inflammation. I am quite sure that the liver will inflame from mere turgescence of blood; and perhaps without inflammation,—from mere congestion,—it will become very large. I am sure that the bulk of the organ will alter, according to the quantity of blood in it; for I have seen it large, and very soon (in a week or two) it has been small again. I have no doubt that internal organs will vary much. They will suffer (if I may so speak) a sort of *erection*, from the congestion of blood. Certain it is, that the liver will sometimes be large from blood; and by active measures will be brought down, in a very short space of time, to the natural state.

But supposing we have used the remedies for inflammation, and that the disease does not cease, and that the size of the liver does not diminish, then we have reason to suppose that there is something more than chronic inflammation;—that there is a change of structure; and it is of no use to push on, with activity, the means for remedying inflammation. Indeed, we should only break up the constitution by them. It may be necessary, if there be pain and tenderness, to bleed occasionally (either by cupping or leeches), to exhibit mercury, and to order low living; but if we push these things far, we frequently break up the patient’s constitution, without affording him any relief. It is often necessary to support the strength well, and even to give the patient stimuli, in order to enable him to bear up against this organic disease.

*Diagnosis.*—With regard to the *signs* of organic disease of the liver, we may sometimes make it out very well, by the edge of the liver being well defined;—running across, and being hard, and even sharp. Sometimes the most easy way of discovering an indurated liver, is not by pressing hard down around the region of the organ; but by putting our hand over it, and suddenly bringing down the fingers. Frequently the liver is an inch or two from the surface; and if we press it regularly, we may not feel it; but if we press the integuments down upon it, we feel it in a moment. Occasionally we may discover *tubercles* in the liver.

*Varieties of Organic Diseases in the Liver.*—With regard to chronic disease of the liver, we must recollect that the liver, like the kidney, consists of two parts; the one sanguineous and red; and the other white or yellow,—containing bile. They are not divided; but throughout the liver there are two constituent parts, lying in juxta-position. Now sometimes it is only the *red* portion of the liver that is hypertrophied; so that the organ is enlarged and red. Sometimes it is the *biliary* portion;—the bile-tubes are all in a state of hypertrophy; and then we have a *pale* liver,—a liver enlarged and pale. Sometimes, without being enlarged at all, it will be pale. The *red* part is *atrophied*,—the vessels shrink; and the *biliary* part is *hypertrophied*; or, if not hypertrophied, it is *indurated*; or, if not indurated, it remains as it was; but as it has a preponderance over the *red* portion, the liver looks *pale*. These changes sometimes occur throughout the liver, and sometimes only in spots; so that here and there one portion of the liver is firmer and

redder than it should be; while, perhaps, in other instances, the *biliary* portion is hypertrophied here and there,—giving it a mottled appearance.

*Gin-Liver.*—Sometimes the hypertrophied portion of the liver has the appearance of white lines running along it; and sometimes of granules,—varying in size from that of pins' heads, to that of hazel-nuts. There is a difference of opinion, among morbid anatomists, with regard to this affection; which has been called “gin-liver,” and which is the most common of all organic diseases of the liver. Dr. Baillie and others supposed that it was caused by minute yellow tubercles throughout the liver; and Andral imagines that it is a mere hypertrophy of the biliary portion. Cruveilhier has given a good delineation of this disease; and has called it “small brown tubercle.” I suppose, as it is a “*gin-liver*” in this country, it is a “*brandy-liver*” in others. Perhaps “*alcohol-liver*” would be the best name. It occurs in spirit-drinkers in one country, just the same as in another. There is the same punishment for them all. I presume that the constant use of alcohol, induces a chronic change of the biliary portion of the liver;—causes it to become hypertrophied, and indurated;—just as any serous membrane will become (from other circumstances) indurated, opaque, and hard. This is the history of this particular matter.

Sometimes this morbid change occurs more in one lobe than in another. Sometimes the liver is increased altogether; and sometimes, instead of being *increased*, it is *shrunk*. The liver generally feels very hard on the external surface. Frequently it is indurated in particular portions; but wasted on the whole. I think that, in by far the greater number of cases, a “gin-liver” is of a bright yellow colour; and generally there is more or less ascites. The peritonæum over the liver is generally more or less diseased. It is particularly opaque and hard.

*Fatty Degeneration of the Liver.*—Perhaps the disease to which the liver is most liable, is that of becoming fatty. The liver is sometimes exceedingly fat. We know that the liver naturally contains fat and cholesterine; and these matters will sometimes exist in a great degree. When the liver has degenerated into this fatty state, instead of being indurated, it is usually soft and flabby. Sometimes it is grayish or whitish; and such is the quantity of fat deposited, that on cutting or handling it, our fingers become greasy; and in those parts which are the most fatty, it appears as if there were no blood at all. This disease, like every other, will affect either the whole liver, or only portions of it. This state is frequently united with phthisis. It is a disease seen continually;—without the person having been addicted to drinking, or having imbibed any bad habits. It frequently occurs in young persons.

*Encephaloid Disease of the Liver.*—The liver is also subject to encephaloid disease;—to what is called “*fungus hæmatodes*.” This is much more rare than either of the other forms of disease to which I have adverted;<sup>a</sup> but when fungus hæmatodes has existed in the extremities, then it is very common for a collection of this nature to take place in the liver. Occasionally, I believe, encephaloid tumours are said to be found in the liver, without the disease occurring in other parts; but more frequently they are found in combination with disease of the extremities. These tumours are, of course, white; and sometimes there are tubera, producing an elevation on the external surface;—bumps. They are of various sizes;—some existing near to the surface, and some towards the centre of the organ; and, when cut, are found to contain a brain-like substance.

*Scrofula, Scirrhus, and Melanosis of the Liver.*—The liver is also subject to another disease,—to a new formation; namely, *scrofula*. Scrofulous tumours take place, from time to time, in the liver; and they are, of course, white. The encephaloid tumours look exactly like them. Cruveilhier has given some good representations of them. The scrofulous disease is sometimes mixed with *encephaloid* matter,—with “brain-like” substance; and sometimes there will be a mixture of *scirrhus* with it. I have frequently seen scirrhus in other parts, with scrofula de-

<sup>a</sup> See Pages 885 to 889.

posited in its neighbourhood; and so it is in the liver. Occasionally *melanosis* exists in the liver;—the black deposit of which I formerly spoke.

The foregoing are the chief organic diseases of the liver. Besides inflammation, we may have enlargement from congestion of blood, or from abscess;—we may have the red part hypertrophied here and there,—so as to give the organ a mottled appearance; and indurated at the same time,—so as to give us red tubercæ;—“tubercles,” as they have been called in this country; but I would rather say “tubercæ.” Then we may have the *biliary* portion hypertrophied; and that is called “gin-liver.” In addition to that we may have encephaloid tumours;—resembling the brain in structure, consistence, and colour; and perhaps with blood effused in them here and there. Lastly, we may have scrofulous and scirrhus tumours, and melanoid deposit.

*Size which the Liver may attain.*—Mr. Gooch, a surgeon, mentions that he saw a liver which weighed twenty-eight pounds. I have frequently seen it reaching into the pelvis. It is a curious circumstance, that we sometimes meet with a liver thus enlarged, which has caused no suffering at all. The patient has never complained of pain; but has felt weak, and has wasted a great deal. This is particularly the case in women. I have frequently examined women in this state; though, during life, they were not known to have disease of the liver. They never drew attention to the abdomen; but merely said they were weak. It shows the necessity, when we cannot understand patients, of having them placed in bed; and of examining them from the throat downwards,—over the heart, lungs, and abdomen. In that way we continually meet with something, which was not in the least apprehended.

*Hydatids of the Liver.*—The liver is very subject to the formation of hydatids. The kidneys and the liver are the two organs of the body, which are most subject to the formation of hydatids. The true animal nature of these hydatids, has not (I believe) been pointed out in the human subject; though it has in sheep. In the latter they have been observed to have a contractile power; but this has not been noticed in human beings. The appearance, however, is so much the same, that one must suppose them to be real hydatids. They are sometimes inclosed within others;—like pill-boxes. Sometimes they are attached by peduncles, hanging one within the other; and sometimes they grow to the outside of each other. A representation of them is given in Dr. Baillie’s work. Sometimes they are attached to the liver externally;—hanging to it: but, generally speaking, they are enclosed in a cyst. Sometimes they are found in the middle of the substance of the liver. The cyst which contains them is usually hard, even cartilaginous. I believe they have two coats; and, when dead, they have no longer a globular appearance; but are like skins, or half-dried mucus. In sheep, I believe, they are seen to have a neck and a mouth.

I had a very remarkable instance of this description, in a lady who had laboured under chronic hepatitis for fifteen years. At last she began to cough, and to spit hydatids; and died. On opening her, I found a large cyst of these hydatids, attached to the concave portion of the liver, on the right side. In the middle of the liver, there was another sac filled with them. Ulceration took place, and they made their way through the diaphragm;—the cyst emptying itself partly into the air-passages. Under all this the irritation was so great, that she died.

*Worms in the Liver.*—Worms have sometimes been found in the human liver; and a lumbricus has been found in the ducts; but I should rather think it was not a native; but a wanderer that, being on its travels from the intestines, lost its way.

*Treatment.*—In all these cases, it would be quite fair to have recourse to iodine, in the form of iodide of potassium,—both internally, and rubbed over the indurated part. I have seen large livers,—reaching to the umbilicus, and below it,—reduced by the steady use of iodine, and sometimes iodine combined with mercury. But it is frequently necessary, while doing this, to support the patient well;—especially if we exhibit mercury. Not only should mercury be given with caution, but we should support the patient well; because the dose that is necessary to do good, tends

to impair the constitution. Iodine, however, may be made to do good without injuring the patient. Setons may, perhaps, be serviceable.

The greater number of these cases cannot be distinguished during life. We can tell that there is organic disease, by feeling that the liver is very large and very hard, by the patient wasting away, and becoming sallow and jaundiced; and sometimes we find there are tubercæ (bumps) in the region of the liver; but very often it is impossible to say what exact structural disease there is. If we have seen "fungus hæmatodes," or scirrhus, in other parts of the body, we may suppose the disease in the liver to be of that nature.

### SECTION III.—JAUNDICE.

The next disease of the liver which I shall describe, is one in which the secretion (instead of passing out properly into the intestines) is absorbed, enters into the blood, and tinges the skin and the urine yellow. I need not say that this disease, in common language, is called "jaundice;"—a term which is derived from the French word "*jaune*" (yellow.)

*Synonymes.*—In brutes it is called "the yellows." In medical language it is called "icterus;" which is said to be the name of the golden thrush; and by looking at that bird, like the Israelites looking to the brazen serpent in the wilderness, it was thought those that had the disease would be cured.<sup>a</sup> The thrush, it was said, would die. In ancient nations, the cure of disease was often attempted by looking on certain things; and I suppose it had its origin from what occurred to the Israelites. In Latin, jaundice is termed "*morbus regius*,"—"the royal disease;" and the reason given by several writers is, that in this affection persons require many kinds of amusements, that none but kings or royal persons can command. It is also called, in Latin authors, "*morbus arquatus*;" from the patient having the various hues of the rainbow ("*arcus*."). It is also mentioned under another name,—"aurigo." I presume this has its origin from "*aurum*" ("gold"). The word "*jaundice*" is simple, and a very fine name for "yellow." In the case of poor people it is called, in plain terms, "the yellows;" but if a lady have the disease, it is termed "*jaundice*."

*Symptoms.*—This disease is marked by yellowness of the skin, eyes (conjunctivæ), roots of the nails, and urine. This disease may occur without the *æcæ*s being pale; but generally they are so. The parts which are first seen to be yellow, are the nails and eyes; and they are the parts that remain yellow longest. It is simply for this reason;—the "half-moon" of the nails (as it is called), and the conjunctivæ of the eyes being naturally so very white, we discover in them the slightest tinge of yellow.

*Varieties in Colour.*—The yellow is not always of the same cast. There is a *bright*, a *dark*, and a *green* yellow; and some persons labouring under jaundice, are of a dark olive-colour, so that it borders upon green; and therefore we sometimes hear of "*green jaundice*." If a person be naturally swarthy, when labouring under green jaundice he looks very dark; and then he is said to have "the *black jaundice*;"—so that we have a *green-yellow* and a *black-yellow*. It is a contradiction of terms; but it shows the variety of hues under which the disease appears.

*Yellowness of Vision.*—Occasionally it has happened that patients have "seen yellow." It was maintained, by some, that that was *always* the case. Dr. Pemberton says he saw this occurrence twice; and that, in both cases, the jaundice was not very intense. On the other hand, we every day see cases of intense jaundice, without any yellowness of the vision. Hoffmann says, that twice he saw patients, who declared that every thing appeared yellow. It has happened to me to have two patients labouring under jaundice, who made the same statement. In July,

<sup>a</sup> Moses made a serpent of brass, and set it upon a pole; and it came to pass that, if a serpent had bitten any man, when he beheld the serpent of brass, he lived.—"*Numbers*;" Chapter 21; Verse 9.

1826, I had (in St. Thomas's Hospital) a case of icterus, where there was albugo of each eye,—particularly of the left. Into this eye ran two large red vessels, and with it the patient “saw yellow;” but the right eye, which had no inflammation before the cornea,—into which no large vessels were running, saw things in their natural colour. In 1827, I had another hospital-patient, who “saw yellow” with both eyes; and in him the conjunctiva immediately around the cornea,—quite at the edge of the orbit, was greatly inflamed. In 1831, I saw a patient labouring under jaundice; and he said that, at the beginning of the disease, he “saw yellow.” He did not know whether his eyes had been inflamed; but there were several tolerably large vessels running, not quite to the cornea, but pretty close to it. When patients “see yellow,” it is from the serum of the blood being conveyed before the pupil, through the cornea. It must be accounted for in that way. In the second case of this occurrence which I met with, I was prepared for inflammation of the eye, by having noticed what I did in the first case. I looked carefully at the man's eye, the instant he told me that he “saw yellow;” and I found, as I expected, that it was in a state of inflammation. Whether this will always be observed when patients “see yellow,” I do not know; but it affords an explanation of the circumstance, and is worth investigating. If a person labouring under jaundice be blistered, the fluid from the blister is yellow; and the serous fluids within the body, are found to be of the same colour.

*The Blood loaded with Bile.*—It is worthy of remark, that the blood of jaundiced patients is loaded with bile. Hunter thinks that the artificial mixture of bile with the blood, produces coagulation; but I think that a quantity of bile much too small to affect coagulation of the fluid, may nevertheless be sufficient to give a tinge to the serum.

*Internal Symptoms.*—Besides these visible symptoms in jaundice, there are several others. Patients generally complain of languor, and very frequently of drowsiness, but still more frequently of a dead weight,—a load at the epigastrium; and of tenderness, and sometimes actual pain, at the hypochondrium. In fact, this is a disease which every day occurs in conjunction with hepatitis; and is, in many cases, merely a symptom of it. There is frequently loss of appetite, nausea, and vomiting; and there is one curious symptom in the disease, which is very common indeed; and that is an itching of the whole surface. People say “they could tear themselves to pieces.”

*Occurs at all Ages.*—Jaundice, like so many other diseases, occurs both in young and old persons. Infants often have it a few days after birth, and some perhaps at birth; and the oldest persons are liable to it. In infants, it appears to be produced from the very slightest causes; and it is cured with the utmost ease. In general, it is a slight disease, arising from slight causes; and may be cured by slight remedies.

*Yellow Skin not Peculiar to Jaundice.*—Sometimes we see yellowness of the skin, not as the result of jaundice, but in fever; namely, that which is called “yellow fever.” The yellowness is not universal in this case. It occurs particularly about the neck; and it appears rather to arise from the disordered state of the blood, or an altered condition of the blood as to some of its constituents;—exactly as we see it in bruises. After a certain part of the blood has been absorbed from an ecchymosis, a degree of yellowness remains; but that is not jaundice. Occasionally, after the bites of certain serpents, and the infliction of wounds by the bite of certain animals, the skin will become yellow; but this does not appear to be jaundice.

*Predisposing Causes.*—Some people would appear to have a constant predisposition to this disease; and it may be hereditary. Persons who have been in warm climates, are much more predisposed to the disease than others.

*Exciting Causes.*—The *exciting* causes of it, are any circumstances that will produce inflammation and congestion of the liver. Whatever will produce hepatitis, or cause great congestion of the liver, will produce jaundice. It may arise, not only from cold and wet, and from long-continued heat, but also from the suppression of a discharge; by which a congestion of the liver will be produced. It

will arise from any thing that causes an excess of bile; for occasionally the fæces, in this disease, are not white. Bile passes into the intestines; but so much is secreted, that all does not escape; and a portion goes into the blood. Malaria seems to have a tendency to produce it in hot climates, and in the hot seasons of other climates. Persons exposed to the influence of malaria, are very subject to have more or less jaundice among them, as well as other hepatic affections.

*Local Causes.*—It may be produced by a variety of *local* causes;—any thing which will cause pressure upon the parts through which the bile is conveyed. Mere costiveness has been known to give rise to it. Tumours occasioned by an enlarged pylorus, or by an enlarged head of the pancreas,—tumours of the omentum,—diseases of the liver,—the lodgment of a calculus in the ducts, are also common causes of this disease. If a portion of liver becomes harder than it should be, and perhaps rather enlarged, the bile may be obstructed in the liver itself. Sometimes pregnancy causes it. I have frequently seen jaundice in pregnancy;—not, however, as the result of pregnancy; but as the result of inflammation of the liver; and which disappeared under the treatment for common inflammation, while the pregnancy went on. It is supposed to be occasionally produced by thick bile; if there be any obstruction to the bile, its fluid parts may be absorbed, and it will thus become inspissated; but there is no proof that this is the *cause* rather than the *effect* of the jaundice. It has been known to be caused by a lumbricus sticking in a duct of the liver. I mentioned, when speaking of worms in the liver, that a lumbricus has occasionally (as was supposed) lost its way, and wandered into the liver;<sup>a</sup> and if it stick there, it may cause jaundice. If the ducts themselves become thickened by chronic inflammation,—if they become hypertrophied, their canal may be so much diminished, that the bile cannot easily pass; and consequently we have jaundice. I have seen jaundice from a great many of these causes; and in 1829 I met with a case, in which it was occasioned by a great number of fatty deposits, all round the ducts. Sometimes the ducts are impervious from original malformation. There are a few instances of this upon record. It would appear sometimes to be produced by spasm. I have known some persons, on eating certain articles, to be seized with violent pain at the pit of the stomach; and the next day an attack of jaundice has appeared. It has been produced by mental causes. Many persons have become yellow from fright. I believe that, in general, people from fright look *blue*; but sometimes, from being exceedingly frightened, persons will have a fit of jaundice. Occasionally the disease has arisen, not from terror, but from long-continued grief and anxiety of mind.

*Enlargement of the Ducts.*—When the ducts have been obstructed, they are generally larger than they should be; and Dr. Heberden is said to have seen them dilated to an inch in diameter. Sometimes, however, no obstruction is found. I have opened several persons who have died, not *from* jaundice, but *with* it, in whom I could see no obstruction whatever; and Sir John Pringle mentions, in his work on Diseases of the Army, that one of the army-surgeons told him of a case of jaundice, in which there was no obstruction; but in which the slightest compression caused the bile to flow.<sup>b</sup> Andral, I find, says that he has seen the same occurrence.

*Artificially induced.*—We may produce this disease artificially, by opening the abdomen, and passing a ligature round the intestines, a little below the “*ductus communis choledochus*.” Portal has done this (he says) in six dogs; and they all became jaundiced. If we tie the lymphatic duct, the same circumstance will occur; and the absorbents of the liver have been seen, after such an experiment, to become loaded with bile. It has been said, however, that the blood from the lymphatic veins was found, in such an experiment, to stain paper yellow;—much more so than the blood from the choledochus.

*Pathology of Jaundice.*—There was a doubt at one time whether, in jaundice, the bile found its way to the blood by means of the absorbents, or by regurgita-

<sup>a</sup> See Page 890.

<sup>b</sup> “Observations on Diseases of the Army. By Sir John Pringle.”

tion to the veins. A short time ago, it was not supposed that the veins would absorb. Before the absorbents were discovered, it was supposed that the veins performed that office; but afterwards, no one allowed that they would absorb at all; and now again it is said that they *do* absorb.\* While it was believed that the veins did *not* absorb, some contended that, in jaundice, the absorbents took up the bile; and others contended that it worked its way into the veins. Experiments were then made; and it was observed that the absorbents of the liver were loaded with bile; and that the *lymphatic* veins were more tinged with it than the *jugulars*. If the veins absorb as well as the absorbents (properly so called), we may suppose that, as the greater portion of bile which found its way into the whole system of blood, passed through the lymphatic veins, those veins would contain a greater portion of bile than any others.

*Prognosis.*—With regard to the *prognosis* of this disease, it must depend entirely on the cause. Jaundice is nothing more, in most cases, than a symptom of some disease; and according to the nature of that disease must be the prognosis. Some are very ill in jaundice, and die *with* it; and others labouring under it go about with little indisposition;—they scarcely know that they are ill; they only look very yellow. In that form of jaundice in which the yellow verges to green, and which has been called “*green jaundice*,”<sup>b</sup> recovery is very rare. When we see an individual labouring under jaundice, with his eyes yellow enough, but with a skin of an olive-hue, we may (without asking a question) fear that the individual has a disease, from which he will not recover. Dr. Baillie says that, in the whole of his practice, he never saw more than two persons recover from green jaundice. Generally, where the jaundice is of this green hue, there is some organic disease of the liver;—either of the whole or of a portion of it.

The disease sometimes lasts a very long time. The *fæces* are in general white; but very often they are bilious. Dr. Baillie says that, in green jaundice, the *fæces* are usually white,—as in other kinds of the complaint; but he has often seen them very pitchy. He says that there is but little pain felt; that there is seldom any ascites; and that he seldom knew it arise from intemperance. The reason that he assigns for the latter circumstance is, that it so frequently occurs in women. Some women, however, are intemperate enough. He considers it as a symptom of something which is fatal. Dr. Cheyne mentions that the jaundice of children is dangerous, if it be of a saffron-hue. In children the complaint is generally trifling; but sometimes it is not. Mr. J. Pearson (a surgeon of great practice in London, a few years ago) said that he knew a family where there had been eleven children, ten of whom died of jaundice within the month;—the disease having begun a few days after birth; and that the eleventh died of the same disease at six years of age;—evidently showing the hereditary nature of the disease. What was the cause of it in this family, I do not know.

*Treatment.*—In the *treatment* of jaundice, we have first to consider whether any inflammation exists;—whether it is a case of hepatitis; and if it be, we must treat it on the common principles of inflammation of the liver;—in proportion to the weakness on the one hand, or the strength on the other. In cases of jaundice, mercury answers better than any other purgative. I have frequently made experiments, and have exhibited common purgatives in some cases, and mercury (so as to affect the mouth) in others; and I am sure that patients have recovered more quickly by the latter mode, than by the former. In mild cases, however,—where there is only congestion of the liver,—the disease will yield to common remedies; and many cases will get well of themselves. But if the disease be more severe, it would be right to employ mercury, and perhaps to bleed in the arm.

*Treatment of the Spasmodic Form.*—The disease may be characterized more by spasmodic pain than by inflammation. There may be occasional pain at the pit of the stomach, or on the right side, rather than constant pain and tenderness;

\* Consult, on this subject, Dr. Graves's Lecture on the Absorbents; of which a new edition has been published.

<sup>b</sup> See Page 891.

and in that case the hot-bath and opium are among the best means. But in such cases as these, if we find the patient's pulse constantly quick and strong, one of the best antispasmodics we can employ is bleeding. If the pain is not constant, but comes on at intervals, and not with a constant severity, we may look upon the disease as, to a certain extent, spasmodic; and there opium and the hot-bath will be very useful. But if there be general tenderness besides, and bleeding be at all admissible, it will answer exceedingly well. It will be more effectual, and much better, to combine the opium with a full dose of calomel. This will prevent constipation, and produce a free discharge from the alimentary canal. In these spasmodic cases, in addition to the common treatment for hepatitis, we should give a large dose of calomel (ten or twelve grains), and a few doses of opium;—perhaps two grains, or more, in a dose. A poultice over the part is also very useful.

This sudden pain with jaundice, is no proof whatever that the case is one of gall-stones. Where there is no jaundice at all, but where a patient is seized with sudden pain at the pit of the stomach, many persons say he has gall-stones; and if, in addition, there be jaundice, then they consider the matter as certain. But mere spasm of these parts will produce this violent pain, and perhaps giddiness likewise. We may suspect that there are gall-stones, but frequently we have all the symptoms without it; and we have no right to assert that a person has gall-stones, unless we see them pass, or they have been discharged. When we consider that, from eating something which is indigestible, a person will be seized with violent pain at the pit of the stomach, and the next day will have an attack of jaundice, it is clear that this occurrence may be produced without the presence of gall-stones;—it is obviously caused by something which has irritated the parts.

*Chronic Jaundice.*—The greater number of cases of jaundice yield to purgatives, or to the treatment of hepatitis; and if we find such severe pain as I have now mentioned,<sup>a</sup> anti-spasmodic treatment will generally get rid of it. But the disease sometimes lasts a long time,—becomes *chronic*; and it is necessary, after we find no more pain,—no tenderness on pressure, to make the patient take free exercise, to have the parts well rubbed, to recommend the use of the warm-bath, to exhibit mercury,—so as to produce a mild affection of the mouth, for a greater or shorter length of time,—and to make a free use of purgatives. When the disease becomes chronic, it will frequently go away under the use of these means. The parts seem to fall into an atonic state. Supposing that the affection continues in spite of all these means, then we generally have reason to suspect that there is disease of the liver. If there is induration or enlargement of the organ, or a degree of ascites, or any kind of dropsy; if persons waste more and more; and especially if the tinge becomes green, after having been the plain ordinary yellow;—then we must form an unfavourable prognosis, and suspect disease of the liver. In the case of enlargement and induration, it is pretty well proved; and then the remedies for diseased liver should be employed. Setons over the part, and the exhibition of iodine, will be the best means that can be resorted to; and we must keep up the patient's strength as much as possible.

With respect to this chronic jaundice, Van Swieten records a curious case; which was cured by making a man imitate Nebuchadnezzar. Van Swieten says that he persuaded a poor man, in an obstinate case of jaundice, to live upon grass for two years, except during that part of the winter when there was none to be got. He made him eat the tenderest grass, and also that which was first mowed; and he made him take that which was in flower. The man “confessed that, for some time, this diet did but little please him; but after a time he was well contented, and could easily distinguish the best pastures by the flower of the grass.” This I can imagine. At last he became a general nuisance to the farmers; for Van Swieten says that he was obliged to eat his diet secretly; and that the farmers, finding he had so large an appetite, often gave him a quick repulse. The man, however, was perfectly cured.

<sup>a</sup> See the previous Paragraph.

## SECTION IV.—BILIARY CALCULI.

*Symptoms.*—We can do nothing to dissolve gall-stones; but when they are passing, we may lessen the pain. It is said, that when they pass, the pulse is not quickened, as in inflammation; but that, on the other hand, it frequently becomes slow. I believe that this is generally the case; but the same circumstance will occur in a case of pure spasm. Sometimes however, the pulse is increased to above a hundred; there is sudden pain in the part; and there is vomiting. Sometimes there is *great* pain, which is relieved by pressure;—it is mere *spasmodic* pain. Sometimes there is shivering. The patient has no increase of temperature; and the treatment will be the same as that for spasm; because we cannot say whether there is a stone or not. But if the patient have passed gall-stones before, and the same symptoms occur again, then we are authorized in concluding that they arise from gall-stones.

*Usual Seat of the Gall-Stones.*—These stones are found in the ducts of the liver itself; they are also found in the gall-bladder, in the cystic duct, and in the “ductus communis choledochus.” If they exist in the cystic duct, of course they will not produce jaundice, unless they happen to be so large as to press upon the “ductus choledochus,” or the hepatic duct; but though they will not produce jaundice, yet they will obstruct the course of the fluid from the gall-bladder; and it will become distended, to a great amount, by its own secretion. There is, at St. Thomas’s Hospital, a very extraordinary specimen; in which, from an obstruction in the cystic duct, the bladder went on secreting mucus, till at last there was what is called dropsy of the part; but no obstruction of the cystic duct can produce jaundice. There must be obstruction in some of the ducts of the liver, in order to produce jaundice; but gall-stones are found in all parts of the organ.

These calculi are most frequently found in the gall-bladder itself; next to that, in the cystic duct; next to that, in the “ductus choledochus;” and next to that, in the hepatic duct. There can be no doubt, therefore, that they are generally formed in the gall-bladder itself.

*Their Number.*—The *quantity* of stones found will vary, from one to an immense number. It is said by Dr. Baillie,<sup>a</sup> that a thousand have been found at once in the gall-bladder. The preparation is now to be seen in Dr. Hunter’s collection.<sup>b</sup> An incision is made into the bladder, to show that it is crammed full of stones. Dr. Baillie has given a representation of the case. I once took out of the gall-bladder of a patient at St. Thomas’s Hospital, between three hundred and four hundred stones; which had given rise to no symptoms during life. The patient had not complained of the least pain; nobody knew that there was any thing extraordinary in his inside; and he died of a very different disease. Nothing is more common than to open persons who have died of disease unconnected with the liver, and who have never complained of a pain in the side; and yet to find several gall-stones.

*External Aspect.*—These biliary calculi are sometimes rough, and sometimes smooth. They acquire a smooth surface from lying and rubbing against each other; but this very same circumstance causes them to be angular. They have a sharp corner and edges; although the surface between the angles may be perfectly smooth. Those in the centre are generally oval.

Some of them are white, others are black; some are black externally, and white internally; and some have a shining and semi-transparent fracture.

*Size of Gall-Stones.*—Gall-stones are seen of all sizes;—from mere grit, to the size of the gall-bladder itself. They will very often pass without pain; for I have found them in the motions, without any pain having occurred. If they are very large, they will occasionally produce no pain;—provided they lie still, and do not attempt to escape; but if nature make an attempt to get rid of them, the pain is

<sup>a</sup> In his “Morbidity Anatomy,” Chapter 10; Section 9.

<sup>b</sup> At Glasgow.

very considerable. Dr. Heberden mentions,<sup>a</sup> that in the gall-bladder of Lord Bath (preceptor to George the Third), there was found a stone which weighed two drachms; and yet that it caused no symptoms. They were surprised to find the stone there. Dr. Baillie says that he saw one the size of a hen's egg.

*Mode in which Gall-Stones escape.*—They will pass through the ducts even when very large; for the ducts will dilate incredibly. We know that the female urethra may be dilated to so great an extent, that a large stone may be extracted from the bladder, without an incision. A very large calculus has been known to pass through the “ductus communis choledochus,” without ulceration having been discovered after death. Dr. Heberden, as I have already mentioned,<sup>b</sup> states, that once the “ductus communis” was distended to an inch in diameter; but not unfrequently, when the stones are large, they will escape by an abscess,—just as pus will do from the liver,—either externally or internally. Adhesions may take place externally, between the gall-bladder and the parietal peritonæum. An abscess forms; and the stone comes out through the abdominal parietes. But, more frequently, adhesions take place between the bile-passages and the intestines; into which the stones escape, and are discharged by stool.

*Size they may attain and yet be discharged.*—It is astonishing how very large a calculus nature will get rid of, and yet the patient do well. A calculus two inches and a quarter in length, three and a quarter in circumference, and weighing one ounce, two drachms, twenty-three grains, was discharged from a person who lived after it, and did perfectly well. Dr. Pemberton states that a stone has been discharged, two inches and a quarter in length, and one inch and a quarter in breadth. In the “Medical Gazette” for March 1, 1828,<sup>c</sup> there is an account of a stone an inch and three quarters in length, three inches and a quarter in breadth, and weighing two hundred and seventy-eight grains. A stone measuring an inch and three-eighths in length, and three inches and three-eighths in transverse circumference, is mentioned in the twelfth volume of the “Medico-Chirurgical Transactions” (Page 255). It had passed by ulceration; but the individual died. There is a curious instance of one an inch and six-tenths in length, and an inch and one-tenth in breadth, which was expelled, and the patient recovered. As it went down the intestinal canal, it stuck in the sigmoid flexure of the colon; and there gave all the signs of strangulated hernia;—so that, before its escape from the intestines, it did serious mischief. Yet there had been no suffering previously. It was not known that the cause of the disease was a stone.

*Constituents of Gall-Stones.*—Some of these stones appear to be nothing more than inspissated bile; and these are bitter to the taste, soluble in water, and burn to a cinder. But the greater part of the biliary calculi are not of this description. They are of an oleaginous character; and, if melted, will take fire, and burn like wax. The shortest way to ascertain their nature, is to scrape them a little; and they very soon melt. Some are resin, some are cholesterine, and some are picromel.

*Internal Appearance.*—Those gall-stones which are waxy (I only use the word in the common vulgar acceptation,—meaning “to burn like wax”), are of a greasy character, are laminated within, and are frequently crystallized. Sometimes, however, they are oleaginous. Generally they are in plates,—laminated; but sometimes there are crystallized radii, passing from within outwards. Occasionally they are a mere amorphous mass. Now and then they have been found to contain phosphate of lime; but when stones in these parts contain this material, it is doubtful whether they are biliary concretions. Two cases of this kind are related by Andral; but there had been such obstruction, that no bile could have entered the gall-bladder, for some time. The cystic duct was obstructed; and calculi appear rather to have been the result of a secretion of the inner surface of the gall-bladder;—just as stones may be found in the urinary bladder.

<sup>b</sup> See Page 893.

<sup>c</sup> No. 13; Volume 1; Page 370.

## SECTION V. DISEASES OF THE GALL-BLADDER.

With regard to diseases of the gall-bladder itself, I may mention that it is rarely ulcerated. Occasionally its coats are very thick; occasionally it is hypertrophied; and it has been known to be completely ossified. Sometimes it will waste away; sometimes it will have tubercles in it; and sometimes there are hydatids in its substance. Now and then it has been ruptured. A woman came one day to St. Thomas's Hospital, and fell down dead; and, on opening her, the gall-bladder was found to have been suddenly ruptured. Death, I understand, took place instantly.

## CHAPTER V.

## PATHOLOGY OF THE STOMACH AND INTESTINES.

BEFORE commencing the consideration of particular diseases of the stomach and intestines, it may be advantageous to give a short general account of the morbid appearances observed in this part of the body. But, in the first place, I shall direct attention to the varieties which are observed in the *natural* state of the parts;—according to the portion of the canal which we examine, and according to the age of the patient.

*Natural Appearances.*—If we examine the inner surface of the stomach and intestines of a living animal, that is making no effort at all,—so that its circulation is perfectly free, that surface is found to be rather redder than the inside of the cheeks;—the mucous membrane of the former, is rather redder than the mucous membrane of the latter. In some animals, after death, the mucous membrane is pale, or at the utmost only slightly coloured; but here, again, much depends on the mode in which the animal dies. If we kill it by putting a stop to respiration, these parts will become of a very red colour, or very dark; and there will be great congestion of blood. But if, on the other hand, we kill the animal by hæmorrhage, these very parts will look paler than they were during life. The internal surfaces of the body, are liable to exactly the same changes of colour as the outer. If a person die from strangulation, the surface of the body will perhaps be of a dark red colour,—more or less; whereas, if he be bled to death, he will become pale. Now we are to generalize these changes; and be prepared to expect circumstances quite analogous in the inner surface.

*Causes of increased Redness.*—If we look at the stomach during digestion, or if we look at the inner surface of the upper part of the small intestines during chylication,—when their great function is going on,—we shall find the parts redder than at any other time. This, of course, will occur at different periods of the day;—according to the shorter or longer time that has elapsed since food was taken into the stomach. Any obstruction to the return of the blood, will make these parts redder than they should be; and perhaps darker. Hæmorrhage may take place from the inner surface of the stomach, or from the inner surface of the intestines,—from the great accumulation of blood; and, as impediments to the circulation are very common just before death, we, more frequently than not, find these inner surfaces red and dark-coloured;—at any rate, *partially* so.

*Colour Influenced by Decomposition, Situation, and Age.*—I mentioned formerly,—when describing deceptive appearances with regard to inflammation,—that we may produce these changes at pleasure, accordingly as we examine a body a *longer* or a *shorter* time after death;—having first placed a certain part in a dependent situation, so that the blood may gravitate in a certain direction.<sup>a</sup> If we

<sup>a</sup> See Page 81.

place a certain portion of the intestines in a dependent situation,—lower than the rest, the blood will of course gravitate to it: and if we allow a long period to occur before we examine the intestines again, according to the length of that period, the situation of the parts, and the quantity of blood in the body, shall we (*cæteris paribus*) find them darker. From the natural arrangement of the parts, we generally find that those portions of the intestines which are in the pelvis, are of a darker colour than the others; and the *posterior* surface of the stomach, is darker than the *anterior*;—merely from the gravitation of the blood; and, of course, darker and darker will the appearance be, according to the length of time before making the examination. If the examination be delayed for a great length of time, —so that decomposition takes place in any degree, and the blood is allowed to transude from the blood-vessels,—we shall find extensive patches of red, and stains along the course of the veins;—just as we observe on the external surface. If a still longer period transpire, the whole of the parts are red. If the blood completely transude from the vessels, it will dye the whole substance; and, from the solid portions being decomposed, we shall actually find more fluid than the blood itself will afford.

In persons in whom the intestines have been diseased during life, we find them of a paler hue lower down than higher up. The lower down we examine them, the greater (generally) is the paleness. They are also pale in youth, and in the young adult period; but in the *fœtus* these very parts are naturally of a rosy hue, and in old age they are of an ash-colour; and not only so, but the veins are seen to be very large. These are the chief varieties as to colour.

*Varieties in Thickness of the Mucous Membrane.*—But there are, likewise, different appearances with regard to *thickness*. The mucous membrane is naturally thickest in the duodenum, and thinnest in the colon; and the mere circumstance of an accumulation of blood, just before death, or after that event, will occasion it to appear thicker than it should be,—without any disease of that particular part; while it always appears thinner in persons who die in a state of anæmia,—who are bled to death, or who have not rallied a little for some time before death, or who die suddenly in an emaciated condition.

*Consistence of the Mucous Membrane.*—There is a great difference, too, in the *consistence* of the mucous membrane in different parts. Generally those which are by nature *thickest*, are also by nature *firmest*. At the pyloric end of the stomach, the mucous membrane is always thicker in health, and more consistent, than at the other extremity; and it is a natural circumstance for the mucous membrane to peel off, in large portions, from the inner surface of the stomach. The consistency of the mucous membrane varies, according to the time at which we make the examination. It always becomes less, in proportion as time elapses after death; and, more particularly, if the surface of the stomach be exposed to the air. If it have immediate contact with the air, it loses its consistency much more quickly than it otherwise would.

*Influence of the Gastric Juice.*—The consistency is also variable,—according to the quantity of gastric juice which the stomach contains; for the gastric juice will soften the inner surface, and indeed the whole stomach. This softened state has been seen, very frequently, in persons who have died in perfect health. Where they have been suddenly destroyed by mechanical violence, or by any violence not acting till the moment of death, the mucous membrane of the stomach has been found softened; whereas, in persons who have been weak, and in whom we might expect such softening from disease, we continually find no such appearances. It has also been found, that not merely the mucous membrane, but the whole of the coats of the stomach together, have been softened in these circumstances; and even perforation has taken place; and still further effects have been observed in the other abdominal viscera, from their immediate contact with the part in which perforation took place. On this account it was supposed, by John Hunter, that the gastric juice will not act on a *living* part; but that it has the power of acting on *dead* animal substances; and will therefore act on the stomach, when life is no longer

present to resist it. 'There has been a great difference of opinion on this point. When it was first promulgated it was doubted. It was afterwards believed; but many French writers again doubt it; though I believe we shall see no good reason to suppose it doubtful, if we consider that, at the same time, the parts of the stomach with which the fluid comes in contact are softened; and it is singular that this softening particularly takes place at the posterior part,—where the gastric juice must chiefly have gone. Thus we may have considerable morbid appearances, without any previous disease;—simply from the effect of the gastric juice. At any rate, it is considered that, when the stomach is softened, we may be justified in saying, that the appearances are simply the effect of death;—whether the individual was in health before, or died from an affection of the stomach; and whether it is at the posterior part of the stomach or not; and whether, at the perforation, the parts are rubbed off or not.

*Hypertrophy of the Mucous Follicles.*—Many morbid appearances take place in the intestines, particularly in the mucous follicles. With regard to hypertrophy of the heart, the walls of the left ventricle are naturally thicker in children, than in adults; and many parts in children have been supposed to be hypertrophied, when the greater proportionate thickness of them was simply a natural circumstance. Now the mucous follicles are much more distinct in children than in adults. In fact, in healthy adults they are not particularly seen, except in the cæcum and duodenum; and sometimes, again, at the lower part of the ileum; but in children they are generally distinct enough, through the whole length and breadth of the intestines. These mucous follicles are often seen to be very large after diarrhoea, and other diseases attended by irritation in the alimentary canal; but sometimes they certainly are very large, without our knowing that the individual had suffered any previous disease of the alimentary canal.

*Inflammation may not leave Redness.*—There can be no doubt that a degree of inflammation may exist in the alimentary canal during life, and yet leave no marks after death. It may happen that the bleedings which were instituted, have taken away the redness of the part, and left it perfectly pale; although the powers of life were destroyed by the disease, or (as in some cases) by the remedies. At any rate, it is possible for the disease to kill; and yet for no redness to be discovered after death. We see a similar occurrence upon the surface of the body, when patients have had erysipelas at the time of death. It is not uncommon to see the parts far less red than during life; and perhaps they are not red at all. Again; we see that redness may exist in all these parts, without any inflammation whatever;—that it may be the result of decomposition, or of some mechanical impediment. If the redness be of an inflammatory nature, or if it have been produced by inflammation, it ought to exist in the minute vessels; but still it is to be remembered that redness may occur there, as well as in the large ones, from mechanical obstruction. If the redness exist only in the larger vessels, it is mere congestion; which may arise from many causes, independently of inflammation. If there is mere over-distension of the large vessels, that cannot be considered inflammation; for if it were, it ought to exist in the minute vessels. But even though congestion of blood should exist in the latter, it would not be a sufficient reason for its being inflammation. When the redness arises from inflammation, the large vessels may be over-distended too; but, in inflammation, the small vessels are *first* overcharged, and ultimately the large; whereas, in mechanical obstruction, the large vessels are first overcharged, and ultimately the small.

*Parts liable to Redness.*—The redness may affect the mucous membrane simply in its continuous surface, or it may affect the villous coat, or it may affect the follicles, or it may affect two or three of these parts together. If it affect merely the villous coat, we have simple red points; and it is in the stomach and lower part of the ileum, that this inflammatory redness is chiefly found. This redness is of all degrees of shade. The villous coat may be transparent or not. If it be the follicles which are inflamed and red, there are frequently red circles around them; and

perhaps also on the summit. If these widen and form a border, the follicles are of a uniform redness.

*Hypertrophy of the Mucous Membrane.*—The mucous membrane is sometimes found thickened; and sometimes it is firmer than usual, and will peel off in large portions. If this occur anywhere, it is sure to be met with in the stomach, and large intestines. When it is hypertrophied, sometimes it is as smooth as usual; but sometimes it occurs more at one spot than at another; and the mucous membrane is then exceedingly rough;—that is to say, the hypertrophied parts being very partial, the membrane becomes rugged. It is polished enough; but still it gives a feeling of ruggedness;—it has depressions and elevations. Sometimes the hypertrophy is such, that portions hang into the canal;—we have it really in processes. When it is hypertrophied, there are various degrees of consistency, and various degrees of colour. Sometimes, along with the hypertrophy, there is great irritation, and a great accumulation of blood. Occasionally we have hypertrophy of the villi, and sometimes only the follicles will be enlarged. When the latter occurrence takes place, sometimes the orifices of the follicles will diminish; and if they diminish, they will at last close, or nearly so; and then the secretion accumulates beneath, and dropsy takes place. If the contents happen to be solid, of course we cannot apply the word "*dropsy*;" but the follicles are distended with a soft, thin, caseous substance. Occasionally the mouth of the follicles increases very much. Sometimes they increase by ulceration; and these overgrown follicles are generally seen, like other morbid appearances, at the lower part of the ileum, where it ends in the colon.

*Hypertrophy of the Sub-Mucous Cellular Membrane.*—Sometimes it is not the mucous membrane which is hypertrophied, but the cellular membrane under it;—the sub-mucous cellular membrane. Occasionally it becomes very bulky, or very hard. It falls into a state of scirrhus, and becomes as hard as cartilage. The disease which is called "*scirrhus*"—a specific induration and hypertrophy<sup>a</sup>—frequently takes place. Sometimes, when it has begun there, the membrane on the other side becomes hypertrophied too; but I believe that when scirrhus affects the alimentary canal, it is the cellular membrane under the mucous membrane, that is first attacked. The other coats will sometimes remain healthy for a great length of time; but hypertrophy, ulceration, and other diseases, may take place. This particular affection of the sub-mucous cellular membrane, is very commonly seen at the pylorus; but it seldom takes place, except after the middle period of life has passed. In this affection, it is common for the orifice of the pylorus to become lessened; and the stomach behind frequently acquires an immense size. If hypertrophy and induration (true scirrhus) take place in the small intestines, it generally gives rise to stricture. The canal of the intestines where it is situated, will be diminished; so that stricture is the consequence. We may have a stricture from other causes; but this is a frequent source of it. This change is rarer in the small intestines, than in the stomach; and rarer in any part of the large intestines, than in the rectum. The rectum comes next to the stomach, in point of frequency of this affection.

*Atrophy.*—Occasionally the reverse change takes place. Instead of the alimentary canal being *hypertrophied*, it will become *atrophied*;—it will become much thinner than natural. The coats will waste away. I do not mean that they will be destroyed; but they will become thinner and thinner, until the alimentary canal becomes quite transparent. Atrophy most commonly occurs at the splenic end of the stomach; and, next to that, at the lower end of the ileum.

*Softening.*—Then, again, these parts sometimes *soften*. It is the mucous membrane that is, most frequently, the seat of this disease;—it will become quite pulpy. There are all degrees of softness, till it is absolutely lost, and the disease exists in various directions. When the mucous membrane becomes softened, sometimes the colour is quite natural, sometimes it becomes pale, sometimes it is a dead white,

<sup>a</sup> See Page 197.

and sometimes it is blue;—just as in the case of the brain. I pointed out that, when the brain is softened, there is sometimes a rosy hue of the parts all round. The change of colour in the intestines, is sometimes produced by the loss of vital energy; and sometimes it is the result of inflammation. This softening is very common after chronic diseases;—after phthisis, for example. Sometimes, where we find this softening to be very great, there has been nothing more than anorexia (loss of appetite), and some degree of indigestion. It is common to find this state where persons have been dyspeptic. This affection is, in other respects, similar to the softening of the brain. Occasionally it is *acute*,—takes place rapidly and suddenly; and occasionally it appears to be a very *chronic* change. When it takes place as an acute affection, there is generally a red tongue and vomiting; but sometimes I have seen it where the patient, a short time before, was in perfect health. The same circumstance has been observed, with regard both to the stomach and to the intestines. Sometimes, in the case of the intestines, the disease follows diarrhoea.

*Gelatinous Softening.*—This softening, though it is most usual in the mucous membrane, may extend to all the coats; and the intestines, though at first sight they may seem healthy, yet when examined, appear like jelly. This general softening of the stomach, is most frequent in the splenic end; and I presume that, very frequently, it really results from the operation of the gastric juice; but that, I imagine, is only one cause of the disease. Cruveilhier has given some good representations of this disease. In these cases we may brush the membrane all away. This softening is not to be ascribed to any decomposition of the part. In the case of the stomach, no doubt, it will arise from the gastric juice; but if it occur in other parts of the alimentary canal, it must be supposed to have taken place during life; for the intestines do not become soft by decomposition, unless a considerable degree of time has elapsed. The *brain* will soon become soft; but the *intestines* retain their consistency for a considerable time.

*Experiments on the Gastric Juice.*—Some experiments were made at Stuttgart (at least, cases were published there) in 1818, upon the effect of the gastric juice in producing this softening. Animals were examined before putrefaction had taken place, and the softness was seen in many cats and dogs; so that it appeared to arise from the gastric juice. If they were allowed to remain till putrefaction had taken place, even then there was not more softening, than in those which were examined sooner. The fluid taken from the inner surface of the stomachs of two children, who had died with this softened state of the mucous membrane, was introduced into the stomach of some dead adults; and it soon caused a solution of the solids; whereas, when it was put into the stomach of a live rabbit, it had no effect. I consider this a great confirmation of John Hunter's opinion;—that this softening of the stomach is mainly attributable to death.<sup>a</sup> But it is said, that if the eighth pair of nerves was divided,—so that the powers of the stomach were impaired,—then the gastric juice occasioned softening during life;—exactly as it did in *dead* animals. If these experiments were correct, they were exceedingly curious.

*Softening the Result of Inflammation.*—There can be no doubt that common softening of the stomach and alimentary canal, is sometimes the result of inflammation; for we see symptoms of gastritis during life, and signs of inflammation after death. But gelatinous softening of the stomach, is frequently seen in children, who have not suffered from inflammation; but who have been in a general ill state of health;—who have been weaned when they were not able to bear it, and have not been supplied with proper food afterwards. Thus it appears occasionally in a cachectic state; and very often the parts all around are perfectly healthy.

*Ulceration.*—I will now make a few remarks respecting *ulceration* of the alimentary canal. This is found most frequently in the two lower fifths of the ileum; and, with respect to the large intestines, it is seen more frequently in the cæcum

<sup>a</sup> See Page 900.

than in other parts. It is seen more frequently in the stomach, than in the jejunum, or the duodenum; but it is seen in all parts of the ileum more frequently than in the stomach; and it is seen more frequently in all parts of the large intestines, than in the two upper fifths of the ileum. This ulceration may exist in the centre of inflammatory spots, or in the centre of red patches. Sometimes we find diffused redness. A long tract of the intestines will be red; and we observe ulceration here and there. Occasionally ulceration occurs in parts more or less melted down; and frequently it takes place in hypertrophied follicles:—both in the “*glandulæ solitariae*,” and in the “*glandulæ aggregatae*.” With regard to the “*glandulæ solitariae*,” when they enlarge and do not discharge their contents, they become distended, and are more or less firm;—so that they acquire a conical appearance. They then lose their conical form, and have a central depression on their top;—exactly like a variolous pustule. Their orifices sometimes simply enlarge; sometimes they ulcerate down merely to the level of the mucous membrane; sometimes they ulcerate below it; and then, if they run into each other, a frightful ulceration is produced. Of course the ulceration may go on, till the alimentary canal is perforated; till there is a way through it into the cavity of the peritonæum. Ulceration, like softening, may either be an *acute* or a *chronic* affection. Occasionally we see ulceration in the midst of gangrene. Gangrene is a rare occurrence in these parts; but occasionally there is ulceration and gangrene all around. Sometimes we see ulceration of scrofulous tubercles. There are scrofulous tubercles deposited under the mucous coat, in the cellular membrane; and sometimes we see them under the peritonæal coat, and cellular membrane. In this situation they will enlarge, ulcerate, and go through the same process as in the lungs. It is rare to find them ulcerate outwards, towards the peritonæum; but I have seen a few instances of this occurrence. Most frequently the tubercles ulcerate through the mucous membrane into the intestines. This is sometimes seen in phthisis. There has been a minute abscess in the cellular membrane, under the mucous coat; and the latter has ulcerated through.

Ulceration is seldom the effect of acute inflammation of the *stomach*; but it is a common result of inflammation of the *intestines*. The ulceration is sometimes solitary; but sometimes there is an infinite number. In the stomach, however, they are seldom numerous. They are of all sizes; and they take all directions. Some extend down the course of the canal; and some transversely. Then, as to the edges, we find them just as various. Sometimes they are natural; sometimes they are very thick; sometimes they are very hard; and sometimes they are very soft. The nature of the ulcerations depends upon the depth of the ulcer. If only the mucous membrane be ulcerated through, the case is very different from what it would be if the cellular and muscular coats were ulcerated too; for then we should have peritonitis. There is no proportion between the depth and the length of the ulceration. The intestine between the ulcerations may be in various conditions. Sometimes it is healthy, sometimes it is unhealthy. Not only the mucous, but the cellular coat underneath, varies much as to its condition.

There is no doubt that these ulcers will heal;—just like ulceration in other parts of the body. Every now and then we find ulcers in the intestines in various stages. Some are open ulcers; some are half cicatrized; and others are *entirely* cicatrized. We find portions of the intestines which have evidently been in a state of ulceration, but which have healed; and it is very interesting to meet with an ulcer half healed; for then there can be no doubt of the nature of the affection.

*Perforation.*—Persons who are not known to be particularly ill during life, are sometimes found, after death, to have an ulceration in the intestines, or stomach. They have had some little illness; but perhaps no one knew of it;—they were in apparent health, when they were suddenly seized with violent pain in the abdomen; and they died from perforation having taken place, and peritonitis being set up. Occasionally this takes place where the patient is labouring under some other disease in the abdomen;—that disease not having been known to exist, but, more frequently, it occurs where persons have suffered from a gastro-enteric affection.

Mere softening will produce a perforation;—just as ulceration will do; and sometimes a slough will give rise to the same circumstance; though that is very rare. In brutes, perforation has taken place; and the coats of the intestines have sometimes lost their continuity by distension, occasioned by gases. In horses, this has been known to take place in consequence of vomiting; for vomiting will not occur in them, unless there be such a violent effort as is dangerous to animal life. It has occurred in human beings when the stomach has been diseased. If the stomach be thin, mere vomiting has sometimes caused perforation. Perforations from these various causes are seen, most commonly, in the stomach, and particularly at the lower end of the organ. There can be no doubt that some perforations take place after death; but when they do not, there is generally violent peritonitis.

*Rupture*—Blows on the abdomen will sometimes rupture the stomach and intestines. It might be supposed that, in all cases where violent peritonitis took place from this circumstance, the contents of the stomach would be effused; but that is not the case. It is said, that sometimes very little irritation has been produced, and only chronic peritonitis. But I believe the cases must be very rare;—at least, I have never met with one. Sometimes the opening has been completely blocked up by nature, by means of a piece of omentum or something else; and no mischief has occurred. Sometimes adhesions have taken place, and a fistulous opening has been the consequence; so that some persons have discharged the gastric juice from their stomach, while others have had an artificial anus. In the case of the rectum, these perforations will occur; and we have what is called “fistula in ano.” Sometimes one portion of intestine will perforate into another. Two portions lie together; nature produces an adhesion; one of them becomes perforated; and an opening takes place in the fellow convolution. Occasionally the intestinal canal has been seen perforated from without. When an abscess occurs in the liver, or a stone from the ducts or gall-bladder has got into the intestines, these parts will become perforated from without. Various tumours have been known to ulcerate into the intestines.

---

## CHAPTER VI.

### DISEASES OF THE STOMACH.

#### SECTION I.—ACUTE GASTRITIS.

*Symptoms*.—Gastritis, or inflammation of the stomach, is characterized by an acute and constant pain at the pit of the stomach. This pain is increased on the slightest pressure; and it is likewise increased on swallowing any thing;—particularly if it be hot, or acrid. There is generally also,—provided the disease is violent,—a great sense of tightness across these parts. These symptoms arise simply from the *locality* of the inflammation; but there are others dependent on the *function* of the part which is inflamed. We have nausea, retching, and even vomiting itself;—especially when any thing is swallowed. Sometimes also there is hiccup (*singultus*). A burning sensation is generally experienced; which, for the most part, extends up the œsophagus, and is felt even in the pharynx. It is not uncommon for the epigastrium itself (the external portion of that part of the body in which the inflammation resides) to be hotter than the rest. There is generally thirst, great anxiety, and not unfrequently a feeling of great debility. The pulse is quick, small, and perhaps hard; but there is a great variety in this respect;—just as in inflammation of other parts. The acute form of gastritis, if it be violent and not speedily remedied, soon proves fatal.

*Frequently preceded by Spasm.*—Very frequently, this disease is preceded by merely a spasmodic pain of the part. It is not uncommon (as I shall mention particularly when describing what is called “disorder of the digestive organs”) for persons to be seized with sudden pain at the pit of the stomach;—running through the back; affecting respiration; drawing the patient together; perhaps relieved, at any rate not increased, by pressure; not attended by a sense of heat, but perhaps by a sense of cold; and unattended by any great thirst. So far from the pain being increased by heat or stimuli, it is generally diminished by them. This is evidently a state of spasm; but after it has existed for a longer or shorter time,—if it be not remedied, or if it do not cease spontaneously,—it very frequently degenerates into, or gives rise to, or is followed by, inflammation of the part. We shall then find the treatment we were at first adopting, highly improper. The administration of stimuli does harm; and if we omit the common treatment of inflammation, the patient is very liable to slip through our fingers. We must carefully remember, therefore, that there are two descriptions of pain attacking this part of the body;—the one entirely spasmodic, the other inflammatory; but that the spasmodic very frequently terminates in an inflammatory state.

*Causes.*—Gastritis is produced, in the first place, by the common causes of all inflammations; cold applied to the body, especially when the body is heated. Sometimes it is produced by cold applied to the inner surface of the stomach, when the body is over-heated. Sometimes, when a person is very hot and takes cold drinks, before inflammation comes on, there is a state of extreme debility. Occasionally the power of the stomach seems almost destroyed; the person is very faint; the pulse is small; and sometimes death ensues without any reaction taking place. We sometimes hear of ladies dying suddenly, when they have been drinking cold water, or eating ices, while they were hot. The danger does not arise simply from being hot; for the hotter we are, the more good does cold do. It is not even the simple circumstance of sweating, that makes it dangerous for a person to go into the cold bath, or to roll himself in the snow,—which the Russians do when there is no necessity for it; but it is the circumstance of the individual being exhausted, that makes the abstraction of all stimuli dangerous.\* If we meet with a patient who has an affection of the stomach from exhaustion, the best mode of treating it, is to give a large dose of opium, together with stimulants. If the person recover from this state, it is possible that inflammation may not arise. But sometimes, without such a depression as this, the application of cold to the surface when the body is exhausted, may produce inflammation,—just as in other cases. The external application of cold may produce inflammation of the bowels.

Occasionally gastritis is produced by the sudden cessation of gout. When gout suddenly ceases in an extremity, inflammation of the stomach will occasionally arise; and that of a very dangerous character. But another state of the stomach is frequently induced in these circumstances;—namely, a violent spasm of the part (gastrodynia);—a state to be treated, perhaps, by brandy. Gastritis sometimes occurs sympathetically with an affection of the kidney;—when the kidney is severely affected in various ways. When a stone is on its passage from the kidney, the stomach generally sympathizes; so that vomiting occurs, and sometimes real gastritis takes place. It will sometimes arise from sympathy with the state of the womb. The womb, when diseased, frequently gives rise to nausea and vomiting; and sometimes the irritation may amount to inflammation. This state is very often induced by the passions of the mind. A sudden emotion of the mind, of a very disagreeable character,—great grief,—sudden surprise of an unpleasant description,—a sudden and severe shock,—will sometimes give rise to a spasmodic pain here (“spasm of the stomach,” as it is called); and sometimes to actual gastritis. Great fatigue will have the same effect. Of course it is a disease that is easily produced by any acrid matter. Many poisons, properly so called, produce inflammation of the stomach; but any acrid matter whatever, or any stimulus (properly so called),

\* See Page 114.

—such as a large dose of cantharides, or corrosive sublimate,—or any thing else that can irritate the stomach, may produce gastritis. It occurs likewise in other diseases. In fevers, gastritis of more or less intensity is very common. I mentioned that, in the fevers of hot countries, there is a burning heat at the pit of the stomach;<sup>a</sup>—deserving to be considered as active acute gastritis.

*Morbid Appearances.*—On inspecting the stomach after death, the redness is very seldom universal. It is very seldom that the whole of the inner surface of the stomach is inflamed. Sometimes this is the case; but generally it only takes place at a particular part. When peritonitis exists, that portion which covers the stomach may be inflamed,—the same as any other part; but in general gastritis, properly so called,—gastritis independent of inflammation of the peritonæum,—merely produces local effects on the mucous membrane of the stomach; though occasionally it extends to the cellular membrane between the coats. This disease very seldom induces gangrene. I never myself saw such a thing; but occasionally gangrene does take place. Very seldom does it produce abscess; but occasionally an abscess has been found between the coats of the stomach. We are more likely to meet with gangrene of the stomach after acrid substances have been applied, than in any other circumstances. If caustic substances have been taken, then we may expect gangrene. A slough is produced, which may or may not be thrown off.

*Care required in determining the Cause.*—This disease may arise from acrid or poisonous matters introduced into the stomach, without our being able to discover any trace of them. It is very possible for a patient to have vomited every thing which he took, or for the ingredient to have passed into the intestines, and so to have escaped from the body; and yet sufficient inflammation may have been induced to destroy life. Although it is very possible that death may ensue from things taken into the stomach, we are never justified in saying that inflammation of that organ,—that the various morbid appearances which we see there, have been owing to poison, unless we prove its presence;—unless we discover it in what has been vomited;—unless we find it contained in the alimentary canal, or in what has been discharged, or in a vessel of the contents of which the patient clearly partook. If it were not for an accurate knowledge of this circumstance, we might suspect that poison had been taken, without there being any justifiable reason whatever for the opinion; for the appearances within the stomach, may be precisely the same as those induced by taking poison, or some other injurious matter; when it is simply common inflammation, and the effects of it.

*Treatment.*—As to the *treatment* of the disease, the first point is undoubtedly to discover the cause. It is of very great importance to know whether the disease has arisen from any thing taken into the stomach or not; because, if it have, our first object must be either to effect its removal, or to destroy its power. I need not say, that the most ready mode of emptying the stomach, is to employ a stomach-pump. This is much better than giving an emetic; because emetics add to the irritation, or they may fail. The most powerful medicines are those of an acrid kind. Sulphate of copper is one of the best; and, next to that, sulphate of zinc. These operate immediately, and produce little nausea. Ipecacuanha produces great nausea, and may not effect the purpose after all;—at least, there is less probability of its succeeding, than in the case of sulphate of copper. When we have recourse to the stomach-pump, it would be as well to employ an antidote. If a poisonous acid have been taken, it is better to pump in *magnesia-water* than *plain water*; but if an alkali have been swallowed, then we should have recourse to diluted vinegar. The best plan, in all cases, is to fill the stomach with warm water;—to pump it *in*, and pump it *out*, till the fluid comes out quite clear, and we are satisfied that nothing remains. Provided a stomach-pump is not at hand, an emetic should be had recourse to; but notwithstanding we have done all this, and emptied the stomach immediately, we shall find it of the utmost importance to go on treating the gastritis, as though we had done nothing of the kind. After

<sup>a</sup> See Page 290.

arsenic or corrosive sublimate has been taken, and the stomach has been washed out, and there is no fear from the immediate effects of the poison, gastritis may nevertheless exist, and destroy the patient; or, at any rate, produce great danger; and we must have recourse to the common treatment of gastritis.

When the disease arises from simple cold, or after poisons, it may be necessary to bleed generally or locally. Cupping can hardly be borne; but leeches should be repeatedly applied over the part; and when we cannot employ them any more, blisters should be had recourse to. Cold drinks are grateful to the patient; and there can be objection to ices. There is intense heat, and a great sensation of thirst; and the greatest comfort imaginable seems to arise from cold draughts. The plan is to consult the patient's feelings. If he like cold drinks, let him have them; or if he like ices, there is no reason why he should be debarred from them. We should follow the same rule as in inflammation of the surface;—change these *cold* drinks occasionally for *warm* ones, and let the patient regulate the temperature. Of course it is necessary to keep the intestines in a free condition; and I should imagine it would be better to do this by clysters, than by any other means. The stomach should be left as quiet as possible; and therefore I would trust this part of the treatment entirely to injections. With regard to the exhibition of mercury in these cases, I hardly know whether it is necessary or not, or whether it would be injurious or not. I have occasionally administered it where I was afraid that death would take place, without seeing the stomach irritated by it; but if we remove the cause (which is something acrid), have recourse to bleeding, give the patient cold drinks, and keep the bowels freely open, the inflammation of the stomach is, in general, disposed to subside.

*Conjoined with other Diseases.*—Inflammation of the stomach is very common in many acute diseases. It frequently occurs in erysipelas; and is sometimes evanescent,—will go away without any treatment, if we keep the patient low; but occasionally it requires local treatment. In fevers we must look out for gastritis. In the continued fever of this country,—properly so called,—and many other acute affections, this disease is very likely to spring up; and therefore, in these affections, we should always, from time to time, examine the state of the abdomen.

## SECTION II.—CHRONIC GASTRITIS.

*Symptoms.*—Gastritis is much more frequently a *chronic* than an *acute* affection. When it exists in a *chronic* form, the symptoms are much the same as when it is *acute*; only they are less intense. There is a great sense of heat within the stomach, rising from the œsophagus into the pharynx; great thirst; tenderness of the part on pressure; loss of appetite; nausea; and frequent vomiting. The tongue is *generally* red somewhere;—either at the tip, the sides, or all over; but we may have inflammation of the stomach, more or less violent, without redness of the tongue. We must not depend on the tongue alone. There is generally redness of the tongue; but we are not to say that the other symptoms do not show gastritis, because the tongue is absolutely white, or not much affected. In these chronic cases, there are generally dyspeptic symptoms;—such as a great flatulence, great acidity, and a sense of sinking at the pit of the stomach. The latter is a very common symptom; and, to remove it, people generally take wine and brandy, and make things worse. The want of attending properly to this point, occasions very absurd treatment. I have seen persons, in this affection, have draughts of æther and ammonia, and things of that description;—all of which may be grateful for a time; but which, as patients frequently themselves say, ultimately produce great uneasiness. It is always right, when treating dyspepsia, to ascertain whether there is an inflammatory state of the stomach; for that organ may be in a condition requiring stimuli of all kinds; or, on the other hand, requiring the application of leeches, and making all stimuli and effervescing draughts exceedingly improper. Many persons labouring under dyspepsia, clearly have gastritis; for there is great

pain on pressure; and because they feel a sinking sensation, they drink wine and brandy, and eat meat. I have seen them get completely well, by changing their diet,—without taking any medicine whatever; and, in other cases, by applying leeches.

*Treatment.*—As to the *treatment* of the disease, it is simple enough. Avoid stimuli, apply leeches from time to time, keep the bowels open, and remedy acidity.

A very slight degree of tenderness at the epigastrium, however, is not sufficient to make it necessary to apply leeches, or to lower the patient. When an individual is subject to occasional attacks of pain in the stomach (gastrodynia), there is always tenderness;—merely from the part being stretched. If we have spasms in the calf of the leg, next day the part is sore;—merely from the muscular fibre having been stretched; and if nothing is done to make it worse, it will go away. There is no occasion to apply leeches to the epigastrium, simply because it is tender. There has been, for a certain time, an attack of spasm; which has left a little tenderness of the stomach; and it will yield best to stimuli;—just as a slight degree of inflammation of the eye, is more easily dispersed by washing it with brandy and water, than by any other means. But if there be much tenderness on pressure, and heat extending up the throat, then stimulating remedies would be improper. It is also to be remembered, that a sensation of heat in these parts generally arises from acid in the stomach; and that by giving alkaline substances, we entirely remove it; but we also apply leeches. If, however, we give alkaline substances (such as magnesia and carbonate of soda), a much smaller number of leeches will destroy the acidity. Frequently this is the result of an inflammatory state; and the best way to cure it is to employ leeches; but to prevent the acidity from doing much harm, we should give antacid remedies; or, if there be morbid irritability, such a medicine as prussic acid will be of great service. But of that I will speak hereafter.

*Accompanies other Diseases.*—Chronic gastritis is an accompaniment of many other diseases;—just as it frequently takes place after *acute* gastritis. It is very common, in diseases of the heart, for persons to have more or less gastritis; which, if it rise to any amount, aggravates all the other symptoms. There is tenderness on pressure; and this, perhaps, extends over all the parts; and we find that, some time before, the patient has had disease of the heart. So, again, it is by no means uncommon for a person in phthisis to have more or less gastric affection. In various chronic diseases, gastritis comes on from time to time, and requires to be remedied; or the symptoms of the original disease will be increased. It is well to ascertain, occasionally, the state of the abdomen, when the patients are labouring under chronic affections;—the same as when they are suffering under acute.

#### a. Ulceration of the Stomach.

*Absence of any Diagnostic Sign.*—When gastritis has existed any time, it may perhaps ulcerate the stomach. Such an occurrence is by no means uncommon. I know of no symptom indicative of ulceration of the stomach; and have frequently met with it by surprise. I have known that the patient had chronic gastritis; but there was no symptom that led me to suppose that, in addition to gastritis, there was ulceration. The symptoms are the same in both cases;—tenderness, thirst, a sensation of heat there, dyspepsia, and perhaps emaciation. Sometimes we find pain at one particular part of the stomach; but that may occur without any ulceration. There is no certain diagnosis. We may fancy it to be the case, but our conjecture may be wrong; and we may find nothing but chronic inflammation.

#### b. Rupture of the Stomach.

*Symptoms.*—If the ulceration proceed to an aperture, there generally occurs, suddenly, a fresh set of symptoms. There is sudden severe pain in the epigastrium; and, in a case which I saw, there was also intense coldness; so that the patient held a glass of boiling water to the part, without feeling it warm;—without

being at all annoyed by it. He also drank water so hot, that I could not have put it to my mouth. Affections of the stomach are frequently attended by a want of power to generate heat.

*Generally followed by Peritonitis.*—This pain, after it has existed for a certain time, is generally followed by peritonitis. There is a paper on this subject by Mr. Travers, in the eighth volume of the “*Medico-Chirurgical Transactions*,”<sup>a</sup> in which he states that the diagnosis, in a case of this description, or in perforation of the intestines, would be sudden pain in one part of the abdomen (in the case of the stomach at the epigastrium), radiating from the part; and he considers that the pain would never cease. In a patient of mine, where there was an aperture of the stomach, the symptoms were these. (I had never seen her before; but she was tall and very spare, and was said to have been long dyspeptic.) One day, after dinner, she was seized with a sudden pain in the stomach. It was impossible for me to tell whether this was more than a spasmodic pain; for it was not aggravated by pressure. I gave her laudanum, of which she took sixty drops; but, finding no relief, she took more; and so she went on till, in a few hours, she had taken three hundred drops; and after that the pain ceased. It is not correct, therefore, to say that the pain never ceases. I afterwards found some cases published in France, and also one by Dr. Carmichael Smith, in which the pain went away; and therefore we are not to be sure that the stomach and intestines are not ruptured, because the pain ceases. After twelve or eighteen hours, my patient again had pain enough; for the whole of the peritonæum became inflamed together. This inflammation could not be removed, and she died. From the suddenness of the pain, the great prostration of strength, the smallness of the pulse, and the sinking of the patient, we may imagine that there has been a rupture of the stomach or intestines; and we are not to imagine it the less because, after a time, the pain goes off. If the patient live long enough, peritonitis occurs, from rupture of the alimentary canal; and this cannot be remedied, because there is a local disease which keeps it up. I mentioned before,<sup>b</sup> that these perforations sometimes take place without any sudden symptoms;—that, occasionally, *slow* peritonitis occurs, and gradually leads to ulceration.

*Treatment.*—In these cases of rupture, I should recommend the free exhibition of opium; and, when inflammation comes on, the application of leeches. These measures will lessen the suffering, although we can do no further good.

*Morbid Appearances.*—If the destroyed portion of the stomach owe its condition to an ulcer produced by the gastric juice, the edges are not so smooth, as in cases of simple ulceration; for the gastric juice does not act so very locally; but the parts all around suffer, and become soft. I believe that, where the stomach has been injured, after death, simply from the action of the gastric juice, there is a softened state of the parts immediately around. It should be recollected that the latter circumstance occurs, particularly, at the splenic end of the stomach; whereas common ulcers take place anywhere; and in the latter case, a patient, previously in good health, speedily perishes. Occasionally, notwithstanding that the stomach is ulcerated, no serious mischief arises; because nature produces adhesions around the stomach, and glues it to the liver, the peritonæum, or the omentum; so that, although the stomach is perforated, no aperture exists. Of course there is injury from the ulceration; but none from the perforation.

*Presence of Pus.*—Pus is sometimes found within the coats of the stomach; and sometimes it has been seen diffused throughout the whole of that organ. Between the coats, there has been one sheet of pus; bounded by the peritonæum on one side, and probably by the mucous membrane on the other;—the muscular coat having been destroyed. But sometimes it has been found between the muscular coat and the mucous membrane, and between the muscular coat and the peritonæum. Sometimes a collection of pus takes place in one particular spot. Pus has been found, it is said, on the inner surface of the stomach; but when we

recollect that this part is naturally covered by mucus, and that sometimes this is secreted in great quantity, one hardly knows whether there is really an alteration in the secretion. Still there is no reason why the stomach should not form pus on the inner surface; and no doubt it does; exactly like other membranes; especially as it has been found, occasionally, on the *external* surface.

*Effused Fibrin.*—It is a very rare thing to find *fibrin* effused upon the inner surface of the stomach; yet there is not a mucous membrane that may not form fibrin, under violent inflammation. It is stated by authors, that occasionally a false membrane (as it is called) has been noticed on the inner surface of the stomach. I believe this most frequently occurs in children. It is *before* puberty rather than *after* it, that fibrin is formed in the œsophagus. If we find a false membrane in the œsophagus, it generally terminates at the cardiac orifice of the stomach. So rare is it for fibrin to be formed within the stomach, that even if the œsophagus has produced it, the false membrane has generally been seen to end at the cardia. A layer of fibrin sometimes occurs in the throat; but it has not often been seen to extend lower than the œsophagus.

### SECTION III.—STRUCTURAL DISEASES OF THE STOMACH.

Besides common inflammation and its effects, with which we are now acquainted, the stomach is liable to peculiar structural diseases. Scirrhus, open cancer, encephaloid disease, and melanosis, will occur in the stomach; and will all take place in various parts of it; but they most frequently take place at the cardia and the pylorus. This accords with the general rule that I mentioned;<sup>a</sup>—namely, that the *orifices* of cavities are most frequently the seat of structural disease.

*Symptoms of Scirrhus.*—When scirrhus exists, there may be pain at the spot which is affected; and that pain may go through to the back, and be increased on taking food. Besides pain, there may be all the symptoms of indigestion; and there may be great nausea and vomiting; so that nothing can be retained on the stomach. If it be the *cardia* which is the seat of the affection, the food is generally rejected immediately. I have seen an instance where, the moment the food reached the cardia,<sup>a</sup> a heaving took place; the patient felt as if he were being destroyed by wind; and he said the complaint was nothing but wind. Sometimes the food will pass the cardia, and be rejected immediately, or five or ten minutes afterwards. But if it be the *pylorus* in which the disease resides, then the food will generally be retained for some time;—perhaps for half an hour, or more. There is no general rule for the time. There may be pain in the region of the cardia, or pain in the region of the pylorus. In the case of the cardia, we may find great difficulty in passing a probang into the stomach, for there may be a stricture at the part; but when the pylorus is affected, there is not only severe pain in that region, but at last there is a tumour. In that case, there is generally emaciation, and a sallowness of look;—such as might be called “cancerous cachexia.” The vomited matter is sometimes very offensive,—sometimes bloody; and sometimes the eructations are exceedingly fetid.

*Absence of Prominent Symptoms.*—Nothing, however, is more common, than to have dreadful disease in these parts, with scarcely any symptoms whatever. Every practitioner must have seen extreme disease in the stomach,—great ulceration of it,—decided cancerous and other malignant diseases of this part,—without any pain worth naming;—without any vomiting till just before death, and without any other symptom than perhaps extreme weakness, paleness, and some obscure uneasiness about the stomach; and perhaps not even that. It is sometimes extraordinary to open stomachs, and see the disease which exists there, without any symptoms having taken place, or symptoms of a very slight character. When the pylorus is affected, we occasionally have jaundice, from pressure on the hepatic

<sup>a</sup> See Page 201.

duct, or on the "ductus communis choledochus." Occasionally in this disease, as well as in an affection of other parts of the stomach, there is vomiting of a very fetid secretion, and sometimes of blood; and the blood will pass through the pylorus to the intestines, so as to appear in the motions.

There is not one of the local symptoms of this complaint, that may not be absent. Sometimes there is no vomiting; sometimes there is no pain; and it is only by a very careful observation,—indeed, by considering that there are no signs of derangement of other organs, that we frequently make up our minds that the disease is probably situated in the stomach. Sometimes there is very little more than dyspepsia; and sometimes people eat well, and are but little troubled with indigestion; but, at last, there is generally more or less hectic.

*Obscurity of the Symptoms.*—These scirrhus formations and cancerous ulcerations, as well as other organic diseases, may of course exist at any part of the stomach, as well as at the two extremities; and the symptoms are generally the same. The symptoms are much less likely to be observed in the stomach, if no obstruction is produced. If an obstruction be produced in the pylorus, then we have disturbance; or if it occur in the cardia, there is great difficulty of swallowing, and great pain when the ingesta reach the part. In the case of the pylorus, the stomach becomes so distended,—from the difficulty with which the contents pass out,—that vomiting generally occurs. When there is an obstruction at the pylorus,—either from scirrhus (which is the most common), or any other disease, it is generally noticed, that the stomach acquires a very large size;—owing to the difficulty with which the contents pass through the pylorus.

*Morbid Appearances.*—If scirrhus exist generally in the stomach, the organ becomes very thick throughout, and its cavity is diminished. The mucous membrane looks puckered and ulcerated. When the disease is situated about the pylorus, it may occasion the stomach to become of an immense size; whereas, if it exist throughout the stomach, it may produce very great contraction; for scirrhus causes a shrinking, and produces a contraction of the parts all around, which spreads throughout the stomach; and, in the case of the pylorus, produces such a contraction there, that the food will not pass through. Dr. Baillie mentions that, occasionally, there is simple stricture of the pylorus or the cardia, independently of malignant disease. These two parts are subject to stricture,—just as the urethra is,—without any organic disease whatever.

*Treatment.*—With regard to the *treatment* of this affection, it is merely palliative. Support the patient's strength, and give narcotics, in order to alleviate the suffering and vomiting. There is no medicine with which I am acquainted, that produces so much alleviation in these organic diseases, as hydrocyanic acid. It frequently *arrests* the vomiting for a long time; but it always *lessens* it very considerably. If there be very great pain, it is necessary to employ opium, in order to reduce it. I have used iodine in these cases; with (as I have thought) a certain degree of advantage. In one case of scirrhus pylorus, I exhibited iodine and prussic acid together; and the disease appeared to stop. I have no doubt that the patient laboured under scirrhus pylorus; for I felt the tumour, and the patient had a sallow look, and vomited for a long time. I gave him these medicines as a forlorn hope, and he was much better; but, in a great number of cases, I have not seen any such result as this; and sometimes there has been no benefit whatever.

With regard to stricture of the cardia, some good may be done by mechanical means,—by passing a bougie;—taking care not to pass one so large, as to occasion suffering to the patient. In the case of a contracted rectum, benefit has been said to be derived by the passage of a bougie. Although organic disease cannot be remedied, yet the effect of it in lessening the canal may be diminished; but great care should be taken not to employ it in such a way as to cause injury.

I mentioned,\* with regard to stricture in the œsophagus, that sometimes there is a *scirrhus*, and sometimes only a *common* stricture; and that, besides these dis-

\* See Page 694.

eases, which can be treated only by a common bougie, the parts are subject to spasmodic stricture. The latter case occurs particularly in females; who will sometimes, for weeks together, be unable to swallow; and then they will swallow very well. These cases are to be treated by improving the general health, by the cold bath, and by pleasant occupation of the mind.

#### SECTION IV.—HÆMATEMESIS.

There is one disease to which the stomach is very liable; and that is hæmorrhage. Without the presence of any malignant disease,—without any *organic* disease,—frequently without any inflammation that can be discovered, and frequently without any danger whatever, a quantity of blood is discharged into the stomach. It is usually dark and in large clots. When describing “hæmoptysis,” or “spitting of blood,” I stated that one could not infer, because in these cases the blood was black, that it was venous blood; for if arterial blood be poured forth into a cavity, and lie there, it will acquire a venous character.<sup>a</sup> Its nature is not to be ascertained from the colour; but when we consider that patients will pass a vast quantity of blood in this way, it seems most probable that it proceeds from the veins, where the motion is very slow. We cannot but conceive that, if it came from the arteries, patients would suffer much more depression. We know that a great quantity of blood is sometimes discharged from the pelvis,—flows from the lower part of the alimentary canal, attended with no very great loss of strength; and there the blood is, for the most part, black.

*Symptoms.*—Hæmatemesis<sup>b</sup> is usually marked by nausea and vomiting;—if not by the latter, yet by the former; and by the sensation of a load at the pit of the stomach,—at the epigastrium and left hypochondrium. Sometimes, in addition, there is a great pain there on pressure. The blood, besides being thrown up by vomiting, is frequently discharged by stool.

*Causes.*—This disease occurs very frequently in persons who are dyspeptic; though I do not mean to say that this affection is a symptom of dyspepsia. It occurs far more frequently in females, than in males; and it is common in women whose catamenia are suppressed or diminished. In some persons, it will return at intervals; and occasionally it is periodical.

The ordinary form of the disease,—like a great discharge of blood from the intestines themselves,—is for the most part without danger. Persons *may* die from it; but, for the most part, they recover. Still it may be a very dangerous disease. It may proceed from an ulcer, and we may not be able to stop it; but, for the most part, it would appear that great congestion has gradually taken place in the neighbouring parts;—in the stomach, and most probably in the liver and spleen, and all around; and then this blood, half out of the circulation, is poured forth; and nature is very much relieved by it. It is, for the most part, a passive hæmorrhage.<sup>c</sup> It sometimes arises from an obstruction in the liver and spleen; as well as from the want of secretion by, or discharge from, the womb. It is frequently observed in hepatic and splenic diseases. The danger chiefly depends upon the source whence the hæmorrhage proceeds. An aneurism of the aorta has sometimes opened into the stomach, and given rise to the disease. Occasionally this hæmorrhage is only a part of the affection called “*purpura hæmorrhagica*,” which I formerly described.<sup>d</sup>

*Case.*—I once saw a patient die suddenly, from this affection. I am not aware that he had hæmorrhage before; but he had some pulmonary complaint. He suddenly fell back, and died in a minute or two. Blood came from his mouth; and, on opening the stomach, it was found to be filled to the utmost with blood; which formed a large mould of the organ. I could discover no disease whatever of the

<sup>a</sup> See Page 762.

<sup>c</sup> See Page 139.

<sup>b</sup> From *αιμα*, blood; and *εμεω*, to vomit.

<sup>d</sup> See Page 466.

part, or any vessel that let it forth. Sometimes, in this affection, the internal surface of the stomach is pale; and sometimes it is in a state of great congestion.

*Treatment.*—It may be necessary to take blood from the arm; or it may be necessary to apply leeches plentifully all over the stomach, and then to order blisters. But for the purpose of stopping the hæmorrhage, it is best to give the patient cold drinks; and, if possible, iced water. Give scarcely any food; and not only take care that what he drinks is aqueous, but that it is as cold as he can bear it. The oil of turpentine is one of the very best remedies that can be employed. I do not know that I ever failed in stopping hæmorrhage of the stomach with it. It should be given in small quantities;—twenty or twenty-five drops, every six, or every four hours. If it should create sickness, it is advantageous to unite hydrocyanic acid with it. They may be given conjointly; or the acid may be given a few minutes before. The acid has not the power of stopping the hæmorrhage; but if there be any nausea, it enables the stomach to bear the turpentine much better. I have the highest possible opinion of *lead*, in passive hæmorrhage; but here we can apply the oil of turpentine to the spot which is the seat of the affection; and although I never saw it do good in hæmorrhage from the *lungs*, yet it is superior to lead in the case of the *stomach* and *intestines*. The effect of it, when it comes in immediate contact with the part, is very great; but still it is necessary to keep the patient perfectly quiet. I have had a large number of cases of this disease; and I believe every one of them has done well. I do not remember a case, where the turpentine had not a decided effect in stopping the hæmorrhage.

The foregoing are the principal diseases of the stomach,—with the exception of dyspepsia; which is so connected with an affection of the liver and alimentary canal, that I will bring them altogether under one name,—“derangement of the digestive organs;” and will describe them hereafter.

---

## CHAPTER VII.

### DISEASES OF THE INTESTINES.

#### SECTION I.—ENTERITIS.

*Symptoms.*—We will now pass the pylorus; and consider, first, inflammation of the intestines. In simple enteritis,—supposing it to be active and violent,—we have acute deep-seated pain; and this may occur in various parts of the intestinal region. Although the pain is constant, yet it is aggravated at intervals; and it is increased on pressure. It differs from “a fit of the gripes,” as it is called,—“pinching and purging,”—in this;—that, in common “pinching,” there are intervals of ease, and when the “pinching” is over, the person is comfortable; whereas, in enteritis, although the pain comes on at intervals, yet it is constant;—although it is not of uniform intensity, yet it is always present. This is an important thing to observe; for I have seen persons seized with tormina, which required brandy, or at least laudanum, to assuage it; and then, gradually, the tormina became constant; and there was pain increased on pressure; whereas, before, it was rather relieved by it. When this change takes place, laudanum and brandy would not only be useless, but would increase the pain;—so that bleeding would be required. I recollect one case, where I was with the individual the whole time; and the series of changes was quite manifest.

In this disease, where there is this sharp fixed pain, there is usually great costiveness. The abdomen, after a time, becomes tense; and, from the severity of the pain, there is anxiety of countenance. The tongue grows white, and the breathing

is quickened. Nausea and vomiting soon occur; and if complete obstruction take place, we may have vomiting of *feces*. This occasionally happens; and, formerly, a particular name was given to it;—"the ileac passion"—"*passio ileaca*." The patient lies on his back,—just as in peritonitis; with his body drawn forwards, and his limbs drawn up.<sup>a</sup> The patient lies quiet; for if he move about, he increases the pain. A patient is often disposed to be restless throughout; but, for some reason, he cannot. In these cases the patient keeps his body still; but tosses his arms about. The pulse becomes quick; and it is generally small, and sometimes hard. It is generally in cases of this kind, that we have what is termed a *wiry* pulse;—that is to say, the pulse is as small and as hard as a wire. A thready pulse is one which is as small and as soft as thread. The tongue at last grows brown; and ultimately (provided things go on from bad to worse) the pain ceases; the patient will often bear pressure; the abdomen swells, and becomes very large; and if we place our fingers across it, and strike it, the sound is as hollow as that of a drum. The patient then becomes exceedingly restless, and delirious; the pulse becomes irregular, and very rapid; the respiration is also quickened; and death ensues.

*Morbid Appearances.*—After death, very likely we may find no effusion whatever; but mere redness. Sometimes, however, there is an effusion of lymph upon the surface, and more or less serum;—from the peritonæal coat having suffered with the rest. Owing to the great congestion, a portion of the intestines will sometimes be almost black;—as black as any blood can be. This has continually been mistaken for gangrene, as Dr. Baillie mentions;<sup>b</sup> and as I stated when speaking of inflammation in general;<sup>c</sup> but we find that it resists the fingers in a way that gangrene would not. We know how mere congestion will make a person black in the face. But there *may* be gangrene; though it is a very rare thing. I do not recollect having seen it. The parts become lacerable like paper, as well as black; and they smell intolerably. Occasionally pus has been found in the substance of the intestinal coats. The mucous membrane within, and the serous membrane without, are inflamed; but the chief seat of this inflammation,—producing this obstruction and this violent pain,—I believe is the cellular coat of the intestines. The muscular fibre may be in a state of *hypertrophy*; but I have never seen it *inflamed*. Acute rheumatism is, for the most part, inflammation of the aponeuroses;—even when it appears to be the muscle itself which has been affected. Rheumatism, generally speaking, affects parts which are not muscular; but if the muscle be affected by it, it is only secondarily. We never have an effusion into muscle, or suppuration there, or any thing of the sort. It appears to me that it is the *cellular membrane* of the intestines, that is chiefly the seat of this disease; although the peritonæal coat, and the mucous membrane, may also be inflamed.

*Diagnosis.*—Enteritis is distinguished from *peritonitis*, by the obstruction that is produced,—the constipation; and the consequent effects of it,—nausea and vomiting; and also by the circumstance of the pain being fixed about the umbilicus, which is generally the seat of it; whereas, in peritonitis, it is diffused.

*Causes.*—This disease is caused by any thing which will produce inflammation;—cold and wet applied externally, and cold internally; and it is induced by any thing which occasions obstruction. If there be a hernia, and the part becomes girt, then we have enteritis. If the *feces* become black and indurated, and will not pass, then we may have this disease. Whatever causes an obstruction, is sure to produce this affection; provided it continue sufficiently long for the disease to be set up.

*Treatment.*—When called to a patient in this disease, we must first ascertain the cause of it. Examine every part of the abdomen, and see whether there is not an umbilical, or a ventral hernia; for patients continually have symptoms of this description, because there is a hernia; and the hernia may be so small as to escape attention. A small portion of the intestines may slip down, without the patient

<sup>a</sup> See Page 873.

<sup>c</sup> See Page 108.

<sup>b</sup> In his "*Morbid Anatomy*," Chapter 8; Section 1.

knowing it. Great mistakes will occur, if persons do not remember that this disease may be the result of hernia; and that a patient may have hernia without knowing it. If there be a hernia, that will be treated in the way which the surgeon thinks best; but if there be not, the first thing which we have to do, is to bleed the patient well. We should set him as upright as he can be; and bleed from a large orifice without any mercy. We must of course consider the patient's strength; but we should bleed on till we make a decided impression;—till we knock down the pulse, and make him faint. After this has been done, a very large dose of calomel should be exhibited. A large dose will clear the stomach, as well as a small one; and it will be more effectual in purging. After it has been taken some time, other purgatives should be given; but immediately after it is administered, an active injection should be given; so that, if possible, they may meet half-way, and combine; and then the disease goes away. First bleed very freely, because purgatives will not operate till we have done that; then give a large dose of calomel (such as a scruple) by the mouth; and then administer a strong purgative injection;—containing plenty of salts (combined with senna, if preferred), or extract of colocynth, or oil of turpentine. I would repeat the calomel, in doses of about ten grains, every four or six hours;—giving purgatives, in addition, from time to time, till the mouth is sore; and when this effect is produced, and the bowels are freely open, the inflammatory symptoms generally go away; and as the obstruction frequently arises from mere inflammation, if we remove the latter by bleeding, and produce a mercurial affection on the patient, the former will subside.

It is also well to cover the whole abdomen with leeches. Twenty, thirty, or forty should be applied; and we should then give mercury till the mouth is sore, and follow it up by other purgatives;—such as croton-oil, which is one of the best, and of which a drop may be given every two or three hours. Sometimes I have given a drop every hour. If these measures will not open the bowels, then we shall find it of very great use to employ the smoke of tobacco. A tobacco-clyster is sometimes a dangerous thing; and therefore we should only put a drachm to a pint of water, throw up one half of it, and watch its effects; but the smoke of tobacco is very manageable. There is a little apparatus for the purpose. We must watch the pulse at the same time; and regulate the smoke proportionately, at our discretion. Sydenham was very fond of this remedy; but not more so than it deserved. He says that the smoke of tobacco was, by far, the most efficacious of all the injections he knew. I know many practitioners who now employ this remedy, with very great success. If this fail, there is no impropriety in taking the patient out of bed, and throwing a few pails of cold water hard against the abdomen. That will sometimes open the bowels, when nothing else will. But where there is inflammation, and no mechanical cause that we can discover, the best mode is to treat it as an attack of inflammation; but in the most decided manner. Take care to give purgatives as abundantly as the stomach will bear them, till they produce their effect.

*Similar Symptoms from Spasm.*—This disease is called “enteritis” (from *εντερον*, an intestine; and “itis,”—inflammation); because it is an inflammation of the substance of the intestines. But similar symptoms, in many respects, are produced by mere spasm;—that is to say, perfect obstruction, together with vomiting and violent pain, though pain of a different character; and then the disease is termed colic;—“enteritis” being essentially *inflammation*, but “colic” being essentially *spasm*. When the spasm ceases, however, then inflammation may come on; and we then have a case of decided enteritis.

## SECTION II.—COLIC.

Having noticed that description of obstruction of the bowels which is inflammatory, I now proceed to consider that which depends simply upon spasm. This obstruction of the bowels is called “colic” (from “the *colon*”).

*Symptoms.*—The symptoms of colic are, in the first place, constipation; with violent pain in the region of the intestines;—chiefly, as in other cases, about the umbilicus. This pain, unlike that induced by inflammation, is relieved by pressure; for there is no tenderness. The relief upon pressure is sometimes very great;—at any rate, pressure is always well borne. I have sometimes raised myself on tip-toe, and pressed on the abdomen with the whole weight of my body, and the patient has not complained at all; but, on the contrary, has felt relieved by it. The pain is, of course intermittent. It is not uniform; nor, indeed, is it constant. It will cease from time to time; the person will be perfectly easy; and then it comes again most terribly. In most cases there is vomiting; at any rate, there is nausea. The vomiting may be fecal;—the fæces have been discharged upwards, as in cases of inflammatory constipation. In both cases, however, this circumstance is comparatively rare. The spasms, in these cases, are not confined to the intestines; for we frequently see them in the abdominal muscles; so that they are drawn into large lumps. The recti muscles become particularly contracted; and, sometimes, we may observe retraction of the navel. Sometimes there is tenesmus; and sometimes there is great contraction of the sphincter ani. There is likewise violent pain felt in the loins; there is a high degree of flatulence; and there is no feverishness. It is carefully to be remembered that this state of things, however purely spasmodic it may be, will frequently, if not relieved, run by degrees into enteritis; so that, at last, we have decided inflammation of the intestines.

*Causes.*—The causes of this disease are, in the first place, the application of cold when the body is overheated. This is a very common cause. Ingesta of various kinds, which disagree with the stomach, will give rise to it. Sometimes I have seen it occur from taking bad cider; but in other cases it will take place, not from any thing injurious in itself, but from an idiosyncrasy with regard to it. Obstruction from any cause will produce it. If there be a hernia, colic may be induced, in the first instance, before inflammation comes on. Hardened fæces is another cause of the disease. It is a common occurrence from any of those causes which, after a time, produce enteritis. Sometimes we may have enteritis first, and then colic, and *vice versâ*; though the cause of both one and the other may be the same. A very frequent cause of it is a particular substance; namely, lead. In some persons, a very minute portion of it will induce this affection. A medical man told me that he had it, from a child's cot, newly painted, being placed in his bed-room. We see the affection, every day, in painters; and in persons employed in the manufacture of white lead. Individuals exposed to lead, in any way, are very subject to this disease.

*Morbid Appearances.*—After death, whether the disease has arisen from cold, from acrid ingesta, or from lead, we may find no morbid appearances whatever; but, on the other hand, we sometimes do. This is all a matter of chance. Sometimes the intestines are in a state of great contraction. Sometimes they are more or less inflamed; because the disease has terminated in that way. Sometimes we find the cause to have been something sticking in the way, or mechanical pressure of some kind; or we may find intus-susception,—one part of the intestine running into another. With regard to the appearance of the muscles, they are emaciated, thin, white, and pale. I have seen the muscles so flabby and wasted, that we could scarcely recognize their natural appearance. They have become little more than tendons. When intus-susception has been the cause, we generally find that the upper part of the tract has passed into the lower. Dr. Baillie has given some good representations of intus-susception.

*Treatment.*—Colic may generally be treated, very successfully, by the exhibition of purgatives in strong doses. If the individual be stout, and the pulse will bear it, it is a good practice to bleed him. Bleeding, within certain limits, is an excellent anti-spasmodic;—spasms of various parts of the body will very frequently cease, on taking away blood. It is not always necessary in this affection; but it may be successfully had recourse to, if the pulse will *justify* it, even though it may not *indicate* it; and it may also act beneficially in preventing inflammation.

It is very useful to give a large dose of calomel;—to administer a scruple repeatedly, after longer or shorter intervals; and after we see that it will remain on the stomach, it is right to give some other purgative;—a strong dose of castor oil, or croton oil, or sulphate of magnesia.

*Croton Oil.*—One of the best purgatives is undoubtedly croton oil; and, if we choose, we may begin with it; but it will be of little use to give less than a drop. In severe cases, I would repeat it every hour or two, till it answered the purpose. Some years ago I was called to a case, where the hot-bath, and every medicine in common practice, had been used, except croton oil; and even of that a dose or two had been given. But the case was very severe, and it was necessary to overcome the disease speedily; and therefore I ordered a drop every hour, or half hour, till it should operate. After about six doses, the bowels were freely opened; and the patient became perfectly well. An injection of oil of turpentine will also be found exceedingly serviceable. About three ounces, diffused in a pint of fluid, and forced into the intestines, is of great service. The warm-bath will afford great relief; but it is rather of use as a soothing measure, than in any other way. The great point is to give good purgatives, and croton oil is certainly one of the best; but we may precede it, by way of laying a foundation for its action, by a large dose of calomel. At the same time, whatever good may be done, we should not omit clysters; and I think the oil of turpentine is one of the best.

*Calomel and Opium.*—Some persons always combine opium with the calomel; and the opium may frequently do good by alleviating the spasm. This is a case in which opium may act as a purgative. By relaxing the spasm, it may cause the bowels to open; and it is thought that it very much reduces the pain, and makes purgatives and calomel stay better on the stomach. It is therefore said, that we ought always to give a larger or a smaller dose of calomel (a scruple or five grains, whichever we may prefer) united with opium, and repeat it at certain intervals; but I have found the bowels open, just as well, without opium; and then there is no trouble afterwards. If we exhibit opium, after a time the bowels are disposed to become torpid; and I am quite sure we shall succeed as well without it as with it.

*Cold Affusion.*—When every thing has failed, I have known this affection of the bowels overcome by taking the patient out of bed, and dashing two or three pails of cold water upon the abdomen. In the particular case to which I have alluded,—in which the patient had taken calomel till his mouth was sore,<sup>a</sup>—before we began with the croton oil, as the object was to open the bowels immediately, he was taken out of bed, and soused with cold water; and he was nothing the worse for it. He caught no cold; but it did not open his bowels. Sometimes it will effect that object immediately;—just as it will relieve spasmodic stricture. If all other things fail, it should be had recourse to.

*Tobacco.*—The smoke of tobacco, also, is exceedingly useful in this affection. It should be used as I have before mentioned.<sup>a</sup> Some have even found the inflation of common air serviceable, by producing a great distension of the intestines. A case of this kind is recorded in the "Glasgow Medical Journal," of 1831.

*Clysters.*—It is well, also, on another account, to administer a clyster; for sometimes the symptoms arise from hardened fæces lodged in the rectum. I have known instances of that description; and, as we do not always know whether such an occurrence has taken place, I would invariably, on that account alone, recommend a clyster. Occasionally, it is discovered, especially in women,—that there is a mass of large hardened fæces there; and nothing will relieve the patient, but taking the handle of a spoon, and picking them out. Practitioners are sometimes obliged to condescend to this; and thus to clean out the rectum.

*Liability of Lead Colic to Recur.*—Supposing, however, that the disease has arisen from lead, it has a great tendency to return. There is this tendency in all circumstances, but particularly in the case of lead; so that after we have once opened the bowels, it is necessary every day, for some time, to ascertain that the

<sup>a</sup> See Page 915.

bowels are still regularly opened. When the disease has arisen from lead, the stomach sometimes remains in a state of spasm: so that there will be an aching pain there, and occasional vomiting;—notwithstanding that the bowels are regularly opened. This is a state which is best relieved by prussic acid or stramonium.

*Alum.*—Some German writers, and Dr. Percival (of Manchester), have praised alum very much. They state, that from two grains to a scruple has been given every six hours, with great relief. However, I should never think of depending upon such a remedy, in cases of colic. It may be very well after the attack is over, for the purpose of keeping the bowels open; but I should not think of placing any reliance on it during the fit. I know that it has been useful; for I recollect, perfectly well, having been consulted by a gentleman who, every six weeks or two months, had a violent fit of colic; so that it was necessary to put him in the hot-bath, and to exhibit a violent dose of purgatives. This always cured him, but left him in a state of great debility; and nothing that was done prevented the recurrence of the attacks. I gave him, three times a day, a scruple, or half a drachm of alum, mixed with ipecacuanha-powder; and it entirely cured him. He took it for a month or six weeks. I saw him, at intervals, for three or four years afterwards; and he had never had another attack. I dare say that ordinary purgatives, in the case of most people, will do very well; but I tried alum, in this instance, with great success.

*Warmth.*—It is useful, where there is a tendency to disease of the intestines, to put the patient on his guard with respect to cold, and to order him to wear flannel about the abdomen. A large roller, wound three or four times round the body, is exceedingly serviceable. It protects the abdomen against cold, and is always useful. In this, as in most other bowel-complaints, it is particularly necessary that the patient should avoid cold feet; for some individuals, if they allow their feet to become cold, always have an attack of colic.

### SECTION III.—PARALYSIS AFTER LEAD-COLIC.

When colic has been induced by lead, we sometimes find that, after the colic is over, the wrist will drop. The muscles situated in the forearm, and belonging to the hand, become paralyzed; so that the patient has very little use of the hand,—perhaps none; and the muscles will, at last, waste away. It is said, by some writers, that the “*abductor pollicis*” wastes more than the other muscles; but I am not aware that it does. Sometimes this will occur from lead, without any colic at all; but generally there is colic; and this is followed by paralysis of the wrists.

*General Treatment.*—This is a state that may easily be remedied. In the first place, withdraw the person from the poison, and prevent him, for a time, from following his occupation. If he be a painter, withdraw him from the lead, or the lead from him. It is also of great importance that he should not wear the clothes which he uses in business. A quantity of lead is still remaining upon them; and that may, of course, keep up the disease. I have no doubt that many painters might avoid the complaint, if they were more cleanly;—if they wore sleeves over their coat; and, as soon as they had done work, regularly put off their working clothes. We cannot, however, persuade men to do this. They will not give themselves the trouble, till they have once suffered for their negligence; and even then, as soon as they recover, they become careless. If patients would adopt the precautions I have just given, no doubt many of them would escape.

*Local Treatment.*—In the way of local application, electricity is one of the best remedies. It should be applied not only to the hand, but to the forearm; because the muscles in both parts are paralyzed. I think I have seen sparks answer better than shocks; and the electricity should be applied, if possible, every day. It has also been recommended that the patient's hand should be supported by splints; and that these should be used night and day, so as to keep the hands in a state of constant extension. This has been recommended by Dr. Pemberton. Blisters are also said to be useful. I have found stimulating applications, of all kinds, service-

able; but particularly electricity. When we apply stimulating applications to the skin, they only act on *internal* parts by sympathy. Friction may make the parts worse; but electricity will go to every spot which is really the seat of the disease. As to internal medicines, I have never seen them do good, except it has been stramonium, or strychnine, or (which is the same thing) "nux vomica." This is a species of paralysis, in which I have exhibited strychnine with decided advantage.

#### SECTION IV.—INTUS-SUSCEPTION.

*Most frequent in the small intestine.*—Intus-susception,—the affection of which I spoke as sometimes giving rise to colic,<sup>a</sup>—generally occurs in the *small* intestines; or else the small intestines slip down into the large,—into the colon. However, intus-susception of the *large* intestines has been seen; for the cæcum and a part of the colon have been found in the sigmoid flexure. Cases have been seen, in which the small intestines (beginning with the duodenum) have all slipped into the large intestines, and the cæcum has protruded from the anus. These are rare cases; but not impossible because they are rare.

*Causes.*—This disease may occur from any irritation whatever; and it has sometimes, no doubt, been temporary; and has passed away. On opening animals, we may sometimes see intus-susception take place before our eyes; and then the parts will slip out again.

*Cohesion may occur.*—However, when intus-susception has occurred, the parts may remain in the situation into which they have been forced; and at last cohesion takes place between the descending portion, and that into which it has slipped; and the mucous membranes may then cohere; so that complete obstruction takes place, and the person dies. Sometimes the part which has slipped in, has only adhered at the upper portion; sloughing has then taken place; and a part of the intestine has been discharged.

*Quantity of intestine discharged.*—The quantity of intestine which, beyond all doubt, has been expelled in some of these cases is surprising; and yet the patient has done well. Dr. Baillie mentions having seen, or known, a yard of the colon discharged from a woman before death. He mentions another person, who lived two years after losing six inches of her colon. It is easy to see how this happens, without any great mischief taking place. Adhesion takes place at the upper portion of that which has slipped down; sloughing afterwards occurs; but the part remains continuous as before,—only shorter. Whether the person has more frequent evacuations after the intestines have been shortened, I do not know; but it is an undoubted fact, that a large portion has been expelled; and yet the person has done perfectly well. Another case is recorded, in which twenty-three inches of the colon were discharged; and in another, twenty-eight inches of the small intestines; and yet recovery took place. Cruveilhier mentions a case, in which eighteen inches, together with the mesentery, were discharged: but the person entirely recovered, after having exhibited signs of strangulated hernia.

It may appear wonderful that so large a portion of intestine should be discharged; but the occurrence is not only mentioned by Dr. Baillie,—who, I suppose, was a man who never told an untruth in his life,—but Andral cites a case, where thirty inches of the ileum were discharged, and death did not take place for three months; and then it arose from peritonitis. He suspected that death took place in consequence of the cicatrix being lacerated by an accidental circumstance; and that, but for that occurrence, the individual would have done well. In the ninth volume of the "Edinburgh Medical and Surgical Journal," a surgeon mentions a case where the colon, the cæcum, and the meso-colon, were all discharged; but, of course, death took place.

*Gives rise to no peculiar Symptoms.*—There is no proof of the existence of this

<sup>a</sup> See Page 916.

condition during life. We cannot tell, in a case of colic, that the patient has intus-susception. I recollect being called to a case of violent colic, which appeared to arise from a man drinking sour cider, and rum, and a number of other things;—having, in a thirsty fit, drunk every thing he could reach. Violent colic suddenly took place; and his bowels, from that moment, were confined. He had castor-oil, croton-oil, olive-oil, hot-baths, cold-baths, and every thing that could be devised; but no evacuation was produced. He survived a fortnight; and, at the post-mortem examination, intus-susception was found. Portions of the intestines were perfectly coherent together;—forming a solid mass; so that there was no continuation between the upper portion of the intestines and the lower; but the circumstance was not known before death. There was no particular tumour to be discovered. From what I have read, and occasionally seen in dead bodies, I do not think that, in a great number of cases, there can be any sign whatever. The disease has occasionally been suspected, however; and, indeed, I suspected it in the case to which I have just referred.

*Treatment.*—Some persons say, that we ought to cut down upon the part;—that we are not bound to wait for the person's dying. Now the case ought to be very clear indeed, before a man's abdomen should be opened, and an attempt made to untwist his intestines directly. It has been proposed by some to cut down upon the part, wherever the seat of the pain is; but this is a very fallacious guide. We sometimes have pain at *one* part of the abdomen; and, after death, the obstruction is found to be at *another*. But if, after symptoms of colic, a tumour be produced, the surgeon might then take into consideration whether he would cut down or not.

## SECTION V.—DYSENTERY.

I now proceed to the consideration of another disease, in which there is spasm and inflammation together; and in which there is both obstruction and purging. This disease is called “dysentery.”<sup>a</sup>

*Symptoms.*—The symptoms of this complaint, are a mixture of those of colic and enteritis; so that we have violent pains of the abdomen, called “*tormina*,” we have also a forcing down backwards,—a forcing of the rectum, which is called “*tenesmus*,” and frequently small mucous or bloody stools, together with more or less retention of the fæces; so that there is an obstruction to the course of the fæces, but a great discharge of secretion from the inner surface of the intestines. The stools are scanty and irregular. The discharges are very frequent, but each particular discharge itself is scanty; and when the fæces do come away at all, they are found in hard lumps. Sydenham defines dysentery to be—“frequent mucous stools, with griping.” Dr. Akenside, the poet, wrote on this disease;<sup>b</sup> and he gives the same definition as Sydenham; but he adds to it—“frequent desire;”—in fact, *tenesmus*. The blood which is discharged in this affection, may be either in clots, or merely in streaks; and sometimes it is discharged in very considerable quantity, and quite liquid. Very frequently there are shreds of fibrin expelled; and Sir John Pringle says, that he has seen fatty matters discharged. That I can believe; for I could mention the same with respect to diarrhœa.

*Acute or Chronic.*—This disease may be either acute or chronic. In the *acute* affection, there is violent inflammation as well as spasm; so that there is considerable feverishness, quickness of pulse, heat, thirst, pain in the abdomen, not only coming on in fits, like *tenesmus* (griping), but pain that is constant, and increased on pressure; together with dryness of the skin. This state may go off in a few days, or it may last for a month; after which time, perhaps, we may call it “*chronic* dysentery.”

*Nature of the Evacuations.*—The liver very frequently ceases to secrete, so that no bile at all passes away; and sometimes it is in a state of great irritation; so

<sup>a</sup> From *δυσ*, with difficulty; and *εντερον*, an intestine.

<sup>b</sup> “De Dysenteria Commentarius. London, 1764.”

that it secretes *green bile*, and the *motions* are therefore green. Sometimes, however, the motions appear to be of a pitch-like substance. Sometimes, instead of thick mucus, there is thin serum; and, from there being a little hæmorrhage, this serum is rather red; so that the discharge from the alimentary canal has, very aptly, been compared to the washings of meat. The discharge may be of all colours, and of all qualities; but the fæces are usually retained. If we procure an evacuation of fæces, they come away in hard lumps; which are called "*scybalæ*," and are like forced-meat balls, only hard. Nature gets rid of these balls from time to time. The tongue is foul, and very frequently aphthæ appear;—from the mucous membrane suffering.

*Frequently conjoined with Fever.*—This disease is very common in hot climates; and most common in this country<sup>a</sup> in hot weather. It is frequently united with the fevers of hot countries, and of our hot seasons; and frequently it is conjoined with intermittent and remittent fevers. Sometimes it precedes, and sometimes it follows these. Sir John Pringle and Sir Gilbert Blane both say, that it arises in camps at the same seasons, and in the same circumstances, as bilious fevers. It has now and then, curiously enough, been observed to be vicarious with fever. It will cease in the army and navy, in different parts of the globe, when fevers begin; and will reappear when they cease; but, very frequently, it is united with them. It has been known to coexist with typhus fever; and likewise to alternate with it. When typhus fever prevailed (a few years ago) in Ireland, dysentery prevailed at the same time, and occasionally alternated with it. Very frequently it occurs with disease of the liver; and occasionally it has been united with measles. The causes of hepatic disease, and the causes of fever, affect all parts of the abdomen.

*Chronic form less Violent.*—The *chronic* form of the disease, is much less violent than the *acute*; and is attended with much less pyrexia. Indeed, the pyrexia, in the chronic form, may at last become hectic. The intestines become diseased; suppuration and ulceration occur; and we have hectic fever. Sometimes, in the chronic form, there is no fever at all; for it degenerates into diarrhœa: so that, at last, the patient complains only of mucous stools and tenesmus. The fæces not being retained, it may degenerate into diarrhœa; so that we have dysenteric diarrhœa;—that is, diarrhœa characterized by great griping, and a discharge of mucus. It has been observed, in hot countries, that more stools take place at night, than during the day; and at new and full moons, than at other times. When speaking of remittent fever, I mentioned, that at new and full moon that fever undoubtedly prevails most, and the symptoms are more intense than at other periods.<sup>b</sup> The same has been observed with regard to dysentery. More stools take place at that time;—not from the direct influence of the moon; but, from the high tides that then take place, there is more vegetable decomposition.

*Morbid Appearances.*—After death from the *acute* form of the disease, we see great inflammation of the intestines,—chiefly of the large ones, and particularly of the colon. This disease so particularly affects this part, that some have proposed to call it *colitis*,—"inflammation of the *colon*;" but that would not be quite correct; for it also affects the rectum, and likewise the small intestines. The great seat of the disease, however, is the colon and the rectum. Besides marks of redness and congestion, there is occasionally superficial abrasion of the mucous membrane; and sometimes deep-seated ulceration, and great distension. After the *chronic* form of the disease in the same situations,—namely, the colon and the rectum,—we find great redness and ulceration; but we also find that effect so peculiar to chronic inflammation,—great hypertrophy;—such thickness as acute inflammation will not induce. There is great thickness of all the coats. The rugæ are all greatly enlarged; so that the inner surface is exceedingly rugged, and we see shreds of lymph (sometimes of great length) hanging upon it. Occasionally these changes are seen only in patches; and occasionally they are seen over a very great extent; and, at the same time, red patches are frequently seen in the small

<sup>a</sup> England.<sup>b</sup> See Page 337.

intestines. The colon has been found, after this chronic form of the disease, as much as a quarter of an inch in thickness. Minute abscesses, too, are seen in the substance of the intestines. On opening the glands, we find them so much hypertrophied, as to look like so many warts. Besides the morbid appearances just mentioned, it is not uncommon to find the *liver* in a state of disease. It is frequently in a state of chronic inflammation; and, occasionally, in a state of abscess. The *spleen*, sometimes, is in the same predicament. The liver, however, is much more frequently affected than the spleen.

*Causes.*—As to the *causes* of dysentery, all agree that it is very often produced by changes from heat to cold, and from cold to heat. The tendency to it is greatly increased by long-continued heat, and by fatigue; therefore in those countries where it is continually seen, it frequently breaks out when the army has suffered to a great degree, or there has been a sudden vicissitude of temperature. A cold wet night, after an intensely hot day, will occasionally produce this affection, in a vast number of persons. It is a disease particularly common on board ships, and in camps. Some consider that one cause of it is malaria; and certainly it is a fact, that where malaria prevails to a great extent, dysentery is very common; but as these are wet situations, one hardly knows whether it is the malaria itself which gives rise to it. I mentioned that, with the remittent fevers of hot countries, there are bilious fevers of all kinds.\* It is also undoubtedly produced, sometimes, by bad food; and likewise by bad water. This disease, for example, prevailed in the Penitentiary at Millbank; where there is a combination of unfavourable circumstances. The prison itself is situated in the most unwholesome place imaginable;—as if it were intended to carry off quickly the people who have been placed there; and I believe the allowance of food was not such as medical men considered to be proper. It coexisted there with scurvy, and various other diseases.

*Formerly prevalent in London.*—Formerly dysentery was very common in London, but at present we seldom see it. I scarcely ever meet with a case, except of those who have been in hot climates; whereas, formerly, it was one of the greatest scourges in the metropolis. We find it treated of by Sydenham, as one of the diseases that came daily under his observation. It was one of the great causes of mortality in the city;—just as was the case with ague, plague, and scurvy. I presume it arose, then, from the bad quality of the food upon which people lived, and the bad drainage of the city. As to the ill effect of bad water, it is said that when the disease prevails in ships, those suffer most who are nearest the pump.

*Fruit.*—It has been supposed that fruit produces the disease; but unless the fruit be bad, there is no reason to suppose that this is the case. Of course bad fruit, coming under the head of bad *food*, might produce it; but the mere circumstance of eating fruit at the time when Nature provides it for us, does not give rise to the disease. On the contrary, there are on record many cases of fruit having proved exceedingly beneficial. It is mentioned by Zimmerman, in his work on Experience, that in 1751 a whole regiment, in the south of France, was nearly destroyed by dysentery. The officers purchased the entire crop of several acres of vineyard for the regiment; and not one man died from that time, nor was one more attacked. The work is well worth reading; for it is as amusing as a novel, and full of instruction. Tissot, a French writer, also mentions that eleven persons in one house were attacked with dysentery. Nine of them ate fruit and recovered; but the grandmother, and one darling little grandchild, had wine and spices instead, as being more comfortable; and both died. It was observed in Holland, that the worst flux which was ever known in the army, occurred at the end of July, when there is no fruit but strawberries, of which the men never partook; and that the disease ceased entirely when October arrived, and brought the grapes, of which the men ate very heartily.

*Bad Water.*—Any cause of intestinal irritation may produce dysentery; more particularly when a predisposition has been given by long-continued heat, and by

\* See Page 333.

bad food; under which term, of course, *drink* is included. It is said, that at the old barracks at Cork, the troops had water contaminated by the common sewers, and made brackish by the tide; and dysentery prevailed. This was remedied; and the disease almost entirely ceased. Linnæus's friend, Rolander, had dysentery from drinking standing water out of a cistern of juniper wood. He ascribed the disease to animalcules; but the mere circumstance of its being stagnated water, was sufficient to account for the disease.

*Is it contagious?*—It was formerly supposed that this disease was decidedly contagious, and that it spread most from the stools; so that if any individual followed another labouring under dysentery, for the purposes of relieving nature, it was conceived that he was more liable to catch it, than by simply being with him. Whether it is contagious or not, it is impossible for me to say; but the sporadic cases of chronic dysentery, which we occasionally meet with in those who have come from hot climates, are certainly not contagious. I never saw any thing that could lead to the supposition of the disease being so. I will not presume to deny, that sometimes it may be contagious abroad; but many diseases are supposed to be contagious that are not. I think it may reasonably be doubted whether it is contagious. Some imagine that almost any particular disease, in particular circumstances, may become contagious; and therefore I do not say that it *never* is contagious; but as the disease is seen in England, it certainly is not.

*Mortality in the Peninsular War.*—I mentioned that this was a disease which prevailed particularly in camps, and in the fleets abroad.<sup>a</sup> In the Peninsular war, our army lost no fewer than four thousand seven hundred and seventeen men, by this disease exclusively. In 1812, two thousand three hundred and forty died; in 1813, one thousand six hundred and twenty-nine; and in 1814, seven hundred and forty-eight. The disease is very manageable, if taken in the first instance; but extreme mortality arises from the unfavourable circumstances in which men are placed. From the want of all comfort, and the excessive fatigue, medical men have little chance of doing good.

*Pathology.*—With regard to the *nature* of the disease, it appears to be inflammation of the mucous membrane, together with spasm of the muscular fibres, chiefly affecting the large intestines. One ought not to say "*altogether* affecting the large intestines;" but it affects them much more frequently than it does the *small* intestines. The inflammation gives rise to constant pain, to sickness, pyrexia, and to a great discharge of mucus and blood. The spasm gives rise to occasional severe pain; and to the retention of the feces.

*Prognosis.*—As to the *prognosis* of the disease, that must depend upon the violence of the symptoms; but we always find it mentioned by authors, that one of the worst symptoms that can occur, is the discharge of worms;—as though the worms instinctively knew that the habitation was about to be dissolved;—and that therefore the sooner they quitted it the better;—just as rats are said to quit an old barn, and to look out for a new habitation, before they are turned loose by the destruction of the present.

*Treatment.*—With regard to the *cure* of the affection, the first thing is to remove, if possible, the cause of the disease. If there be a bad quality of the ingesta (whether liquid or solid), or any dampness in the situation, or any contamination of the atmosphere, all this should be obviated;—either by removing the patient from it, or by removing it from the patient; otherwise we are fighting against a double enemy;—both the disease and its cause.

*Antiphlogistics.*—In *acute* dysentery, we have to treat the affection upon a decidedly antiphlogistic plan. It may be necessary to bleed vigorously in the arm; to apply leeches freely and repeatedly to the abdomen; to give mercury, and get the mouth sore; to apply cataplasms of hot moist bran to the abdomen; or, if preferable, to apply them cold; but, in general, the moisture answers much better if it be warm. We must treat it as a violent active inflammation of the intestines.

<sup>a</sup> See Page 922.

With regard to calomel, we shall find that, although all agree upon its importance in this disease, yet that some recommend *large* doses at intervals, and others *small* ones. Those who recommend the latter, would give other purgatives (such as castor-oil) at intervals, for the purpose of emptying the intestines; whereas those that give large doses, trust more to the calomel itself. It is highly necessary, in this disease, to open the bowels well. Notwithstanding the number of evacuations, the fæces are altogether or greatly retained; and therefore it is necessary, not merely to employ the remedies for inflammation, but to empty the intestines thoroughly. Some people would give a scruple of calomel at intervals:—so as to get the month sore as quickly as possible, and at the same time to empty the alimentary canal. Those who give small doses, would give other purgatives in great abundance; but it is necessary to get the bowels open, as speedily and as effectually as possible. It is useful to employ opium at the same time;—on account of the great tendency which there is to severe spasmodic pain. The opium may be united with the calomel; and if we take care to make the calomel operate by means of other purgatives, no harm can arise from it. If castor-oil will stay on the stomach, I should prefer that medicine to salts; because there is, perhaps, a great discharge of mucus; and perhaps there are watery stools rather than fæces; and castor-oil has the property of thoroughly emptying the alimentary canal. Emollient clysters are also of the very highest importance; but nothing acrid should be put into them. Clysters of gruel, containing a certain portion of laudanum and castor-oil, will be much better than clysters containing salts. The patient should be kept without food;—his stomach should be allowed as much repose as possible;—he should be kept very low.

*Ipecacuanha; Antimony.*—Many persons, formerly at least, had a very high opinion of ipecacuanha in this disease. Dr. Akenside, the poet, in his elegant Latin treatise on this disease,<sup>a</sup> recommends about three or five grains of ipecacuanha every six hours; and many persons still give it, and also antimony, so as to create sickness. I have no experience of any such plan. I do not see the utility of causing the patient to vomit in this disease; neither have I ever been able to discover the soothing effects of ipecacuanha. Some persons, when they give purgatives, give ipecacuanha; and say that it has the property of emptying the alimentary canal; but, after repeated trials, I cannot say that I have found that it has any peculiar properties, except that it makes the patient sick. I have been as successful in this disease as in any other, by treating it on antiphlogistic principles;—without exhibiting any thing with the view of producing sickness, or any specific operation. Formerly, various preparations of antimony were given; but I have not found them at all necessary.

*Treatment of Chronic Dysentery.*—With regard to the *chronic* form of the disease, we have to consider whether there is any inflammation still existing. There very frequently is. The abdomen is still tender; and it would be absurd to think of giving astringents, and blocking up the intestines, while that inflammation exists. The readiest way of lessening the disease is, in the first instance, to apply leeches freely over the abdomen, and to throw up a clyster;—taking care that the bowels shall be opened freely and regularly; and when we have done all this, then astringents will be very proper.

*Astringents.*—In chronic dysentery there frequently is no inflammation at all. The time arrives when there is a mere gleet of the surface, or the surface is merely in a state of irritation; and in that condition, opium and astringents of all kinds are exceedingly serviceable. But we may do infinite mischief unless we ascertain, before giving astringents, that there is no inflammation. If there be inflammation, we must treat it accordingly;—by leeches, blisters, fomentations, and things of that description; and we must take care to see that the bowels are regularly opened, and the fæces discharged; because if the fæces are not discharged, and we exhibit astringents, we may produce inflammation, though there was none at first. But in

<sup>a</sup> See Page 59.

the chronic form of the disease, the fæces, at last, are discharged pretty well; and no purgatives are required. Still, however, the character of the acute disease so far remains, that there are bloody and mucous stools, a desire to go to stool, and tenesmus. In this form of the disease, astringents may be given safely, and may be either vegetable or mineral; and it is best to combine them with opium. By far the best astringents that I know, are kino and catechu. It may be right not to give the tinctures; as they may excite the pulse, and irritate the patient. It is best to give the infusions. Opium is very much required in this disease, to prevent griping. As I before said,<sup>a</sup> opium is often very safe and very useful in the *acute* form of the disease;—provided we take care to subdue inflammation, and to keep the bowels open; but in the *chronic* form, it may be given with very great safety;—provided the bowels be regularly open,—as is usually the case. A good mode of exhibiting the opium, is to give the Pulvis Catechu Compositus. It will not irritate so much as opium alone.

*Sulphate of Copper.*—When the ordinary astringents (catechu and kino) fail, mineral astringents will frequently cure the disease; and that which I have been most in the habit of employing, and with very great success, is the sulphate of copper. The way in which I became acquainted with its use, was from hearing a gentleman state that, at the Medical Society at Guy's Hospital, a case had been read of violent chronic diarrhœa; which yielded to nothing but copper. Dr. Sutton, of Greenwich, at a consultation, informed me that he had a very obstinate case; and that, all the other astringents having failed, it occurred to him to try this; and he did so with very great success. I have consequently used it; and it certainly is one of the best, where mineral astringents are required; but it is necessary to remember that we should not give it on an empty stomach; because, if it come in contact with the organ, it will excite vomiting. It should not be given till after breakfast; and that is the case with most acrid substances. If they be not given till the patient has had a meal, they will produce less irritation of the stomach, than if they come in direct contact with it;—which they must do when the stomach is empty. It is right to give this medicine in the form of a pill; because all acrid substances act more powerfully in a state of solution. If it be given in a pill, it comes in contact with a smaller surface; and will therefore produce less irritation than if it were diffused. It is generally right, also, to give it with opium; because, although it is an astringent, yet it is an acrid substance. It has two properties;—the one astringent, the other acrimonious; and therefore it is best united with opium; but I have frequently omitted the latter, and continued the former, with perfect safety. The smallest dose which it is worth while to exhibit, is a quarter of a grain; and we may gradually increase this to three grains; which is the largest dose that patients will ordinarily bear. In fact, many will not bear more than a grain and a half. It produces no constitutional effect. I have known a patient take it for three years, for a peculiar kind of diarrhœa, without any such result. I never saw such a constitutional effect arise from it, as occurs from lead or arsenic, or any other mineral substance. If it produce sickness, we shall find it of great use to give hydrocyanic acid with it. By giving from one to four drops of the acid, according to the necessity of the case, when the copper is taken, we shall find that patients will bear it without sickness or nausea; though without it, perhaps, there would be both. By a steady perseverance with this medicine, or with vegetable astringents and opium,—taking care, at the same time, to have the abdomen well covered with flannel; making the patient avoid cold, and every kind of ingesta likely to irritate the alimentary canal;—and, at the same time, supporting his strength,—we may effect a cure in the greater number of cases. It is a rare thing for me to lose a case of dysentery. I do not know how long it is since I lost one; but certainly it is not a very common complaint.

*Treatment of Ulcerated Intestine.*—In the chronic form, if the intestines be ulcerated, we may still cure the disease; for it is only when there is a very great

<sup>a</sup> At Page 924.

degree of ulceration, that patients die from it. Ulceration of the intestines will heal,—just like ulceration of any other part; but of course we may meet with cases, where medicine can do no good;—where the intestines are in a state of hypertrophy,—look as if they were worm-eaten;—where the mesenteric glands are diseased; and frequently perforation takes place, and the patient is destroyed by peritonitis. A representation of such a case as this, is presented in Dr. Baillie's plates; and nothing can be expected to do any good in it. A surgeon would not be expected to cure a leg or an arm, in such a state as that. If the patient may sink from the disease of a part so unessential to life as an extremity, much more may he do so in the case of the intestines. Some persons recommend other substances in this affection;—such as nitric acid and muriatic acid, united with opium and astringents. One would expect, *à priori*, that such medicines would only cause irritation; but there is testimony in favour of muriatic acid combined with opium; and some say the same of nitrous acid. I have never given acids in the disease. I have known them, when taken in other diseases, produce a pinching in the bowels; and therefore I have never ventured to give them to a patient labouring under this affection.

*Treatment of Tenesmus.*—We shall find it very necessary to alleviate one symptom; and that is the tenesmus. If there be any tenderness about the abdomen at large, leeches should be applied to the anus, as well as to the front of the abdomen; because tenesmus may arise from an inflammatory state. When, however, it does not arise from an inflammatory state, but rather from irritation than any thing else, opium is very useful. It is best to give it in the form of tincture, in a very small quantity of fluid. About four ounces of fluid is the utmost that can be given; because we wish it to be retained, and not to be rejected. Bulk will irritate as well as acrimony; and, therefore, when we are giving it to lessen the pain and tenesmus, as small a quantity as possible should be employed. About forty or fifty drops of laudanum, given in a little starch, will be one of the best injections of the kind. Sir James McGregor says that, in the Peninsula, he found great relief from injections of acetate of lead; so that we might put laudanum into a solution of the acetate of lead. I presume one or two grains of the latter would be enough. We know that lead has a soothing effect on a raw surface, or on mucous surfaces in general; and therefore we can conceive that this would be a proper medicine.

*Mercury in Chronic Dysentery.*—I have never given mercury in the chronic form of the disease. I have always been able to cure the affection, as we see it in this country, without it; and Sir James McGregor says, that in the Peninsula it was worse than useless;—it was absolutely injurious, unless the liver was diseased at the same time. I have repeatedly watched the motions in this disease. In very many cases, they were quite white; and white for a month or two;—more like paste than any thing else; and, without giving any mercury, I have suddenly seen bile in them. The intestines are restored to their function; the health is improved; the liver begins to do its duty properly; and, without exhibiting mercury, the bile will return,—sometimes gradually, and sometimes suddenly. When we consider that mercury renders the body more susceptible of cold, and that our object is to soothe the patient, I would not recommend it to be given in the chronic form of the disease.

*Bandage of the Abdomen.*—I mentioned the necessity, in the chronic form of the disease, of well bandaging the patient's abdomen;\* and some persons, instead of employing flannel, prefer straps of adhesive plaster all over the loins. This might be applied first, and bandages over it.

## SECTION VI.—DIARRHŒA.

I now proceed to the consideration of that disease into which chronic dysentery

\* See Page 925. See, also, Page 918.

degenerates; but which happens every day (indeed I might say every hour) without dysentery;—namely, “diarrhœa.”

*Definition.*—By “diarrhœa” (from διαρρῆω, *to flow through*), is meant frequent liquid, and rather copious, feculent stools;—not dependent upon debility of the sphincter ani. In dysentery the stools are not feculent. When a person is weak in the sphincter ani, he may have stools every ten minutes; but he would not, on that account, labour under diarrhœa. In this disease there is pain only at the time of the evacuation. It is pinching enough, and pretty sharp then; but it ceases as soon as the evacuation is effected; whereas, in dysentery, the griping is horrid; and is not lessened by the discharge of mucus and blood which characterizes the disease. Cullen, in his definition, says there is no preliminary fever; and that the disease is not contagious;<sup>a</sup> but there may be preliminary fever in diarrhœa, inasmuch as it is frequently inflammatory. I should be content with the definition I have given.

*Character of the Dejection.*—The discharge, in this disease, is of all colours;—white, green, black, yellow, and clay-coloured; and of various colours at various times. It is also of all kinds of disagreeable odours;—sour, fetid, and every other variety of unpleasant smell. It may likewise be bloody, watery, mucous, or purulent. Occasionally, the motions can hardly be called *liquid*;—they are only very *soft*. Sometimes they are uniform in their tenacity or softness; and sometimes they differ in different portions. It appears that the discharge is chiefly an increased secretion of the intestines, and sometimes of the liver. Sometimes the nature of the discharge is dependent upon some other organ. The discharge may be purulent;—from an abscess in the liver, or perhaps an abscess in the ovaria. There are all degrees of the disease, and all durations of it.

*Morbid Appearances.*—After death we may sometimes find nothing unusual;—it has been merely an excessive secretion; and, on the other hand, we frequently find all degrees of redness and congestion. Frequently the mucous membrane is found softened; and then it may be either red or white. Sometimes it is *inflammatory* softening, and then it is *red*; and sometimes it is without any mark of inflammation, and is quite *white*. Occasionally the mucous membrane is found very much thickened; and it is also ulcerated. Sometimes the ulceration is a mere superficial abrasion; and sometimes it is very deep; appearing to have begun in the mucous follicles. The mucous follicles may contain (as in chronic dysentery) curdy stuff, and sometimes pus. The follicles are frequently in a state of hypertrophy; and sometimes, without being ulcerated, they contain pus. In fact, we may have all the various states of the intestines which I mentioned, as being seen after fever, and in chronic dysentery.<sup>b</sup> These may occur in the large intestines, or in the small intestines, or in both;—sometimes very extensively, and sometimes partially.

*Causes.*—The *causes* of the disease are, in the first place, too much food. If a person eats a great deal, it must find its way out; and it does. There must be more *exportation* in proportion to the *importation*; so that diarrhœa is very frequently an effort of nature; and the person would be badly off if he had not diarrhœa. An alderman, I should think, would suffer severely, if he had not many attacks of diarrhœa, in the course of a season. Improper articles of food will give rise to diarrhœa. Every body knows, that if he take something which disagrees with him, he will suffer from it;—nature makes a proper effort to get rid of it. Frequently *new* articles will occasion diarrhœa. If a person eat something to which he is not accustomed, although it may be excellent in its kind, it will frequently give rise to the disease. Children suffer exceedingly, if they are weaned too early, or too suddenly. There is a peculiar kind of diarrhœa in infants, called “weaning-thrush.” If children be weaned before nature is ready for the change, or if the change be made too rapidly, diarrhœa takes place. Children cannot bear the sudden change from milk to common food; whereas, if they be strong, and be

<sup>a</sup> “Dejectio frequens; morbus non contagiosus; pyrexia nulla primaria.”

<sup>b</sup> See Pages 294, 295, and 921.

weaned gradually, they bear the alteration of diet very well. This is precisely analogous to what is observed with regard to fish. There are *salt-water* and *fresh-water* molluscæ; and if we put the *salt-water* molluscæ into *fresh* water, and *vice versa*, they will die; but if we mix the water gradually, so as to lessen the saline quality of the water by degrees, they will live in it as well as if they had been always accustomed to it; and the same with regard to the *fresh-water* molluscæ living in *salt-water*. A new article of food is a common cause of diarrhœa, both in children and adults; but especially in the former.

Cold, especially after heat, is another common cause of this complaint. The mind, too, has a very great effect. Fear is generally considered to operate very strongly on the intestines. Malaria is enumerated among the causes of this disease. The suppression of other discharges will sometimes produce it. If a person have been accustomed to a running of the leg, and it is suddenly stopped, he may think himself well off if he have diarrhœa; because, if he had not, he might have apoplexy. Metastases are causes of it. If another disease cease, it is common to see diarrhœa begin. If inflammation suddenly cease, diarrhœa may occur. Dysentery is mentioned as one cause of it. This is an affection which is very commonly produced by other diseases; or it becomes a part or consequence of other diseases. In fever, for instance, diarrhœa is very common;—it becomes a part of the fever. It is very common after measles. Measles affect the intestines almost as much, I was going to say, as the skin; but, at any rate, they affect them in a very remarkable degree. So, again, in phthisis;—the same state of the body that gives rise to that affection, causes at least a great irritation of the alimentary canal.

*Causes of the Paroxysms.*—Besides the exciting causes of the disease itself, there are exciting causes of *paroxysms*,—if I may so call them. For instance: when a person is labouring under diarrhœa, if he move about much, he will very likely be obliged to go to stool; and again, on taking food, many persons immediately have a desire for a motion. Sometimes it is *warm* food, and sometimes it is *cold*, which has this effect. Frequently persons can take nothing warm, without having a desire to go to stool; and the application of cold to the surface, will bring on the desire in a moment. The best plan is to sit quietly by the fire without moving.

*Treatment.*—As to the *treatment* of this disease, if it be slight, it is best to do nothing at all. It is generally a mere effort of nature, to relieve herself from something improper, which has been taken inwardly; or from the depressive action of an agent applied to some other part of the body. When cold has been applied to the surface, nature relieves herself in this way; and if the individual do not make it worse, he is sure to get better.

*Diluents.*—But if it be necessary to adopt any measures, mild diluents, in the first instance, are the best things. Every old woman knows that barley-water, chicken-broth, and so on, help to sooth the intestines. To these some persons add mild purgatives; and some are in the habit of giving the patient a dose of physic, whenever he has diarrhœa; and, in general, there is no harm in it. If any thing acrid have been taken, it may aid nature, and the disease may cease so much the sooner; but if there be merely an excessive action going on,—from a depressed circulation of the surface, or the passions of the mind,—it is difficult to see what good can be done by a purgative. As the disease, however, in most instances, if left to itself, would cease without any remedy, a purgative has frequently the credit of curing it, when it deserves no credit at all.

*Opiates and Astringents.*—If, however, the disease run on, it may be necessary to stop it; and, for this purpose, various opiates and astringents are given. It would be well, in these cases, to avoid giving tinctures; because there is frequently an inflammatory state; and an astringent is just as good *without* the alcohol, as *with* it. I need not enumerate chalk-mixture, catechu, kino, and all the various modes in which opium is given. In very severe cases, the same treatment should be adopted as in chronic dysentery;—the exhibition of sulphate of copper, and other astringents. For what I know to the contrary, we might give these

astringents with safety at the beginning. I have done so; but it is too powerful an astringent to be frequently required. The sulphuric, nitric, and muriatic acids, united with opium, have been given in these cases, as well as in dysentery. Dr. Moses Griffiths, who invented a mixture of iron called "*Mistura Ferri Composita*," recommended in diarrhœa a mixture, consisting of two drachms and a half of tincture of rhubarb, and six drachms of linseed-oil;—a portion of which was to be given two or three times a-day. I have known this administered with good effect. The rhubarb, besides being a moderate purgative, is an astringent; and the oil is a demulcent. The one soothes, the other astringes; and it is thus that it has a good effect in chronic diarrhœa. It is also given in chronic dysentery. This remedy is contained in some of the *Hospital-Pharmacopœias*. It is a very disagreeable remedy;—as vile as can be well conceived; and I myself never found it necessary to give it; but it is sometimes a good medicine in this disease.

*Leeches and Blisters.*—It is always necessary to ascertain carefully, whether the disease is inflammatory; as it generally is, to a certain degree, after measles; and we should always press the abdomen, and see whether there is tenderness; because we may in vain give diluents, opiates, and astringents; and may even make the patient worse by them than if we did not give them at all, if there be a degree of inflammation which we do not take means to remedy. I have seen many cases of diarrhœa, which have resisted all the means that could be adopted; but which ceased presently on applying leeches to the part, or on the application of a blister. In fact, this disease is frequently nothing but an inflammation of the mucous membrane; and it will cease on applying blisters. It is frequently necessary, while doing this, to give opium and astringents; and we may do so with perfect safety, if we attend to the inflammation. Indeed, if we attend to the latter, there is frequently no occasion to give the former at all; and if we do *not* attend to it, we make the patient worse by their exhibition. The first thing to be done, therefore, in cases of this disease, is to inquire into the cause. If the patient have been eating improper articles of food, we must change his diet; if there be any inflammation, we must treat it accordingly; if there be no inflammation, or not much, then we must exhibit opiates and astringents; and in this way the disease may be cured. The mildest of all astringents, is chalk-mixture and a little laudanum; but if that will not answer the purpose, we must go on to catechu, kino, and sulphate of copper;—taking care that the patient be well purged in this disease,—just as I mentioned in chronic dysentery.<sup>a</sup>

*Diarrhœa with white Evacuations.*—This is the common form of diarrhœa. Occasionally, however, we meet with some singularities in this disease. I mentioned<sup>b</sup> that Dr. Baillie described a particular kind of jaundice;—remarkable for its being green, and for its ending unfavourably.<sup>c</sup> He has also described a kind of diarrhœa, remarkable for the fœces being white, and likewise terminating for the most part fatally. It is described by him in the "*Transactions of the College of Physicians*."<sup>d</sup> He says that, in this particular kind of diarrhœa, the stools are white,—like a mixture of lime and water;—that is to say, like thin mortar, or mortar spoiled. They are also frothy, of a sour smell, very copious, very numerous, and unattended with pain. The disease is so chronic, that it may last for years. It most commonly occurs, he says, in men,—not in women; and more particularly in men who have been in warm climates, and suffered from disease of the liver. He says that the affection may occasionally be suspended, and that the fœces will sometimes become brown; but the disease returns; and the motions become white again, and also fluid. The affection is very rarely removed. The patient wastes away under it, and dies.

*Treatment.*—This is a disease which I have occasionally seen; and though Dr. Baillie could not cure it, I have been successful, in two cases which I have had of it, by treating it in the same way as ordinary diarrhœa;—persevering steadily in

<sup>a</sup> See Pages 923 and 924.

<sup>b</sup> See Page 894.

<sup>c</sup> See the "*Transactions of the College of Physicians*;" Volume 5; Page 143.

<sup>d</sup> Volume 5; Page 166.

the exhibition of sulphate of copper combined with opium; and giving wine at the same time. Sulphate of copper alone might have done. Without giving mercury, the motions of these persons become bilious;—they ceased to be white; and at last they became firm, as well as of a proper colour. One man was a patient in the hospital.<sup>a</sup> He got stout, regained his looks, and would not stay any longer. His disease might return a year or two afterwards; but I kept him there a considerable time, and he remained perfectly well. He had been in hot climates; and, in all respects, corresponded with Dr. Baillie's observations.<sup>b</sup> The other case occurred in a gentleman who had long been in India; and, after persevering with medicine for nearly two years, the disease (I understand) has entirely ceased. He is an old man, whose constitution has given way to the warmth of the climate; and he has had attacks first of one thing, and then of another. Dr. Baillie mentions, that he has tried the ordinary remedies of kino, catechu, and chalk-mixture; but that they have all been unsatisfactory, and have all failed.

*Discharge of Lymph.*—Occasionally, in diarrhœa, very considerable shreds of lymph are discharged. Patients say, that they have discharged great pieces of skin;—that they are sure the coats of their bowels are coming off; and medical men have thought the same thing. Dr. Baillie once believed, that he saw a portion of mucous membrane come away. But he afterwards detected his error; and said that it was nothing more than an effusion of lymph, corresponding with the effusions sometimes found on a serous membrane; and exactly like those tubercular substances, which sometimes come away from the air-passages. Occasionally a large quantity of fibrin is secreted on the inner surface of the mucous membrane, in chronic dysentery; and it will come away in the form of large shreds, or even tubes. I have always seen this form of the disease marked by great pain; and have found it exceedingly obstinate. I have not seen more than three or four cases; but, by the most persevering treatment, I have not done any good. I have merely afforded temporary relief.

## SECTION VII.—DISCHARGE OF FATTY MATTERS.

There is another discharge from the alimentary canal, more curious than that last described, and that is a discharge of fat,—both in a liquid and a solid state. Sometimes it is discharged with diarrhœa; and sometimes without it. Occasionally the lumps come away with great pain. In other cases, it is oil that comes away,—just of the colour of melted butter. My attention has been attracted to it, from having had some cases of this description under my own care. My curiosity was excited; and I was led to read upon the subject.

*Sauvages' Account of it.*—I find that Sauvages, whom I mentioned as having been the first framer of a system of Nosology,<sup>c</sup> has mentioned a “*diarrhœa adiposa*,” and he says that he has known the bowels, after hard riding, pour forth adipose matter. He says that, apparently, this adipose matter had been absorbed by the blood-vessels; where, being mixed with the blood, it rendered the later viscid. It then partly flowed into the intestinal canal; and there, as it were, covered the fœces with butter.

*Cases.*—I found several very satisfactory cases of this disease. There is one of a woman who discharged every day, for fourteen months, a large quantity of yellow fat; which lay on the fœces, like melted butter. Sufficient was collected to fill a number of vessels, and, when thrown into the fire, it burned with a bright flame. After the fœces had cooled, it concreted; and became of the consistence of absolute fat. But (what was singular) there was neither tenesmus, emaciation, nor colliquative fever; and sixteen years afterwards she was in excellent health. This case is related by Tulp; but he says—“What is this to an old woman who, in her seventieth year, voided precisely similar fat from the intestines and bladder?” These

<sup>a</sup> St. Thomas's.

<sup>b</sup> See the previous Paragraph.

<sup>c</sup> See Page 69.

are singular cases; but I believe them. Tulpus adds that, towards the close of the disease in the last case, the patient became feverish, and in consequence emaciated; and that death found her little else than a parched and juiceless corpse. I find another case, where a patient, for some years, had suffered pain in the stomach. Nothing relieved her, and she became worse; when she one day discharged about three pounds of fat; and from that moment speedily recovered. I find another case, where a patient discharged from his bowels, for two years, a large quantity of fatty substance. He grew thin and weak, and then died.

In the "Edinburgh Medical Essays,"<sup>a</sup> is described a case which occurred to a weaver, forty years of age; who, in attempting to take up a very heavy vessel, felt his back-bone crack; which crack was attended with violent pain. Being unable to stand, he fell to the ground. The pain long continued very severe. He fancied that the bone was dislocated inwards; and, in order to reduce it, made one of his neighbours pull his abdomen backwards; while another, getting on his shoulders, pressed them downwards and forwards; by which he thought his loins were made much straighter than formerly; and he had less pain. Some days after this, a country bone-setter undertook to put all the bones right;—making one man pull at his shoulders, and the other at his legs, in a contrary direction. By this extension, he was put to most exquisite torture; and all his complaints were increased. Three months afterwards, he could just manage to crawl out of doors; and then observed among his excrements a whitish substance, about the bulk of a large walnut. It was like tallow, or hardened marrow;—being composed of small globules. It melted on the application of heat. During several days after this, he observed several pieces of the same sort of substance (of the size of kidney-beans or peas) come away among his fæces. He thought all those lesser pieces, if they had been put together, would have been equal to the large piece he passed first.

I had, in St. Thomas's Hospital, a patient with diabetes, who had wasted away. For some reason or other, I happened to see his motions; and there was lying upon the fæces a large quantity of fatty matter,—soft fat; which, he said, was quite fluid when discharged. I looked at the fæces regularly every day; and there was always one or two tablespoonfuls of this fatty matter. I took a part of it to Dr. Prout, and some to Mr. Faraday. It was also seen by some of the first chemists in London; and they found it to be similar to fat. The question asked was—"whether the patient had taken castor-oil?" But he had taken nothing of the kind,—nothing oleaginous. The fat ran away, in this liquid form, with his motions, or after them; and when he had diarrhœa, it came at the top. It was voided like oil; but presently concreted. His wife told me, that this was the first symptom of his complaint. He had formerly discharged an immense quantity of it; so that full one-half his motions were fat. What was curious,—the disease ceased while he was under my care. He died of diabetes and phthisis. I opened him; but there was nothing particular to be found. The diabetes had arisen from organic disease of the kidneys; but there was nothing else to be found there. The intestines looked greasy enough;—they were like paper steeped in oil; but that was all. No oil was found in the alimentary canal. Dr. Prout tells me that, in cases of this kind which have come to his knowledge, there was considerable disease of the kidney.

*Mr. Pearson's Case.*—Mr. Pearson, of Clapham, showed me a quantity of fat which came from an old woman; and said he could furnish me with any quantity. He understood from her, that it was discharged with the urine; but he mentioned the case of a lady, whom he knew very well, who discharged fat both with the urine and with the fæces. He did not attend her; but had been in her company. He had been particular to have the urine by itself; and also to ascertain whether the fat came from the bowels or not; and he clearly ascertained that it came from both. In this case of his, and in my case too, I think the motions were very white. They seemed to be of a viscid nature. It is a curious disease.

*Treatment.*—Mr. Howship, in his book on Morbid Anatomy, mentions the case of a lady, who discharged a great quantity of this fatty matter; and she was cured by giving her a pint of olive-oil. That was an odd remedy. He says she was well from that day, though she had been long ill previously. As “facts are stubborn things,” I gave the man under my care<sup>a</sup> four ounces of olive-oil; and the voiding of fat greatly diminished from that time, and soon ceased. Whether the circumstance was accidental or not, I cannot tell. In “Hufeland’s Journal,” for 1826, is mentioned a case where a quantity of thick oily matter was vomited. There was extreme emaciation; together with a rapid discharge of thick oily matter from the stomach.

*Source of Ambergris.*—The spermaceti-whale is liable to this disease;—what is called “ambergris,” being fat collected in the intestines of spermaceti-whales. As much as one hundred and eighty-two pounds have been found in, or discharged from, the intestines of that animal; and it is said that it has never been found higher than six or seven feet above the anus. This fat is very often discharged, and found upon the shore; but occasionally it accumulates, and the animal dies;—either from the accumulation, or from disease forming in the intestine.<sup>b</sup>

## SECTION VIII.—GASTRO-INTESTINAL CONCRETIONS.

Concretions of the alimentary canal are sometimes discharged, and sometimes collected within; and as they are sometimes found in the stomach, as well as in the intestines, we may speak of them together; under the head of “gastro-intestinal concretions.”

*Biliary and Urinary Calculi.*—In the first place, these concretions may occur without any fault in the gastro-intestinal canal;—they may arise from the gall-passages. Of course if a gall-stone escapes from the ducts, but is not voided, it will be found in the stomach or intestines. Dr. Marcet says, that he once found in the alimentary canal a stone, which came from the urinary passages. Ulceration had taken place; and a communication had been formed between the urinary and fæcal passages. The rectum, in this case, was imperforate.

*Foreign Bodies.*—Occasionally very hard concretions are found. They are often nothing more than hardened fæces; and then they are called “scybalæ;”<sup>c</sup> but occasionally they consist of articles which have been swallowed. I saw a man who had swallowed nineteen clasped knives. He was not believed for some time, but he assured me that he had swallowed them; and, to convince me, he took out of his pocket one of the same size as those he had already swallowed, and put it down his throat. I was frightened, and begged he would bring it up; but it was too far gone. Some persons believed him, and others did not; but at last we could feel them sticking in the abdomen; and ultimately they could be felt, I understand, in the rectum. He discharged fæces containing a large quantity of iron,—blackened; and at last he died in the most horrid torments;—the knives cutting his intestines to pieces. The fastenings of the knives, as solution went on, became less and less secure; the handles separated; and the blades were let loose. After death, a great quantity of knives were found in his abdomen;—some having run through two or three folds of the intestines. It was a frightful sight. Considerable portions of the knives were discharged during life; and these, together with what were found after death, are preserved at Guy’s Hospital. The case is described by Dr. Marcet, in the twelfth volume of the “Medico-Chirurgical Transactions.”<sup>d</sup>

*Various Medicines.*—When a person has taken a great quantity of chalk-mixture, and even magnesia, concretions have sometimes been formed. In the Museum at St. Thomas’s Hospital, there is a preparation where the intestines of a child are

<sup>a</sup> See Page 931.

<sup>b</sup> A Paper by Dr. Elliotson on the Discharge of Fatty Matters from the Intestines, will be found in the “Medico-Chirurgical Transactions;” Volume 18; Page 67.

<sup>c</sup> See Page 921.

<sup>d</sup> See Page 52.

completely blocked up with magnesia. It has the appearance of hard mortar, regularly cemented; and is said to be magnesia. It is necessary, therefore, to be on our guard (when exhibiting chalk, or magnesia) not to give it too long without ordering a purgative,—so as to carry it away. There is on record the case of a person who had taken magnesia for a long time, and suffered a great deal; and who then suddenly discharged, from the intestines, a large quantity of powder of magnesia. It is a fact that, from magnesia or chalk, the intestines sometimes become completely blocked up.

The sesquioxide of iron will have the same effect. When giving that medicine in any quantity, it is necessary to see that the bowels are regularly opened. We may give an immense quantity, if we attend to that point. I related a case where a man took nearly two pounds of it, every day, for some days, when labouring under tetanus (of which he got well<sup>a</sup>); and he regularly discharged large lumps of the sesquioxide. They came away as they would from a horse, covered with mucus, and giving him no pain whatever; but then he had a clyster to prevent any mischief. If a person do not attend to his bowels, a great accumulation may take place in the rectum, and the individual may be obliged to pick it out; but this must be from bad management. I have known cases of this sort occur, two or three times. I had another patient labouring under tetanus, to whom I gave this remedy, and he also got well; but if the nurses did not give him purgatives properly, he suffered pain in the rectum;—the rectum was distended and became dry; and he was obliged to pick the iron out. In his bed was found a shovelful; which he had amused himself, day and night, in removing. I recollect an obstinate hysterical girl, and also the case of a lady, in whom a similar accumulation took place; but, in these cases, it arose from the patients' refusing to let us know the state of their bowels. It is right to know that, if we do not pay proper attention, such things may occur.

Dr. Barlow (of Bath) mentions a case where pills of sulphate of iron were discharged, nine months after they had been taken.<sup>b</sup> This is another general fact, showing that articles may remain in the alimentary canal for a long period before they are voided. Substances which are liable to concrete should not be given, unless we attend to the bowels.

*Larks' Bones.*—Dr. Prout told me, that he was sent for to see a lady from whom some odd things had come away. She had suffered excruciating pain: and it turned out to be from larks' bones. This lady had been in the habit of eating larks, of which some ladies are fond; and she munched the bones. She was a lady of title; but, in consequence of this lark-eating, she suffered great pain. The substances discharged were sent to a celebrated chemist;—in order that he might ascertain what they were. He first discovered them to be bones; and afterwards, from their figure, they were ascertained to be the bones of larks.

*Mustard Seeds.*—It was the fashion, a few years ago, (and I believe it has not yet quite gone out,) for people to stuff themselves with whole mustard seeds. They were thought to keep the bowels very open. Some said it was a good practice; and others distributed pamphlets and tracts recommending it. A gentleman came to me with various odd affections of the alimentary canal, which I could not well understand. Two days afterwards he brought me a quantity of seeds that had come away; and I could not imagine what they were, till at last he told me he had been eating mustard seeds, but had not taken any for six weeks. Though he had given up the practice before he came to me, they had already accumulated in him; and his danger arose from that accumulation. We know that they generally come away whole. One gentleman told me that he sowed some of these mustard seeds, after they had been passed through him; and they produced just as good salad as if he had not used them. Fashionable people have always some whim about them;—they are always taking something; but I believe the day of mustard

<sup>a</sup> See Page 635.

<sup>b</sup> They were "Hooper's Pills," taken for amenorrhœa by a young woman, who has since married, and is now (1812) the mother of healthy offspring. From sixty to seventy were collected from the stools.—*Dr. Barlow.*

seed has pretty well passed by. Mustard seeds will accumulate;—just like other things.

*Hair Balls.*—In cows, we very frequently find, in the alimentary canal, concretions consisting of hairs. They lick their skin; some of the hairs go down the throat with the saliva; and concrete together into a hard ball. They are found, not only in cows, but in many other animals. Millers' horses are said to be subject to these concretions, from the grit of the stone-dust in the mills; and particularly, it is said, when they are fed upon bran. The poor people in Scotland, who eat oaten bread, sometimes have concretions of this description,—formed of the beard of the oat. The outside of such concretions as these, is like velvet.

*Earthy Phosphates.*—It is found that the earthy phosphates are frequently mixed with hair, the beards of oats, or whatever else may have been swallowed; and become cemented together by the phosphates and the mucus. Sometimes, instead of the phosphates being mixed up with the other ingredients, they form into a concretion around a nucleus;—just the same as takes place in urinary calculi. The ammoniacal magnesian phosphates, particularly, will form around a nucleus of any sort. Sometimes the nucleus has been stale fruit; sometimes a piece of bone; sometimes a pin that has been swallowed; and sometimes a gall-stone. We shall see that it is the phosphates, in particular, that are formed around a layer in the urinary organs. In some of these concretions, oxide of iron, oxalate of lime, muriate of ammonia, and muriate of lime have been found. There was a lady who was said to discharge a large quantity of stones, from the urinary organs; but whether she told the truth, I do not know. A medical gentleman was attending her; and he wrote to his friends in London, to know whether they had seen similar wonders. It was very singular that two ladies, in different parts of the country, discharged similar stones; and both cases happened to come within my knowledge. Whether there was any deception or not, we could not tell; but Dr. Prout considered that, if there was not, the stones must have come from the intestines. There was said to be excruciating pain attending their discharge. The stones have the same appearances, and the same chemical qualities; they contain oxide of iron, and phosphate of lime. Dr. Prout considered, that many of these were too large to have passed from the urinary passages; and that the number the patient stated she had voided, must be incorrect. It is true that very large stones will pass through the female urethra; but they would have caused more suffering in the bladder than she complained of.

*Size of Concretions.*—These gastro-intestinal concretions are sometimes very large. I recollect having read of a woman, in whose stomach they were found nearly as large as a hen's egg. The same writer mentions finding some, which weighed four ounces, in a soldier's stomach. In the colon of a young child, one was found which weighed two ounces and a half, and was six inches long. The child died in consequence of it. In the "Philosophical Transactions," for 1686, there is an account of a woman who discharged many, varying in size from a pea to a filbert; and the weight of which amounted, in two years, to five pounds. In the thirty-second volume of the "Philosophical Transactions," there is an account of a pregnant woman, who discharged some concretions that were very large. One of them weighed above two ounces. It is a fact, therefore, that such concretions do occasionally occur. Sir H. Sloane mentions a case, where two hundred were said to be discharged.

These concretions are much larger in brutes, than in the human subject; and also more common. In a brute, one has been found weighing fifteen pounds twelve ounces. They chiefly occur in ruminant animals, and in horses of slow draught; and in millers' horses, which are fed on bran. Both in the brute and the human subject, these concretions are spheroidal or oblong. They take an imperfect polish, are more or less porous, and either are radiated, or have layers. Biliary concretions of both kinds occur;—some disposed in radii, and others in laminae.

*Bezoars.*—Those which are taken in small ruminant animals,—such as the antelope or the goat,—are called "bezoars." The word is said to be derived from

a Persian compound,—“pa-zahar;”—meaning “alexipharmic” (from ἀλεξίω, *to repel*; and φάρμακον, *a poison*). Bezoars were once so valued, on account of their supposed anti-poisonous properties, that one in the East, when very fine, has been sold for six thousand livres;<sup>a</sup> and has been hired, in Holland and Portugal, at the rate of a ducat per day.<sup>b</sup> I have some specimens; but some of them are probably artificial; for, being sold at a great price, they were imitated. They are said to have concentric layers; and sometimes to be crystallized. They will take a polish, and even have a metallic lustre. Mine have evidently been stained. Sometimes there is an accidental nucleus within; and they will rattle. They are found to consist chiefly of vegetable matter; and some have an aromatic smell;—from the circumstance of the animal having eaten aromatic herbs. It is said that it is only those which come from the west, that take a polish; and that the eastern have often a gloss of white. The mode of distinguishing the genuine from the spurious, is said to be this:—if we take a piece of paper rubbed over with chalk, or lime, and draw a genuine bezoar across it, it turns it green, or of an olive-colour; whereas, if it be spurious, the colour of the paper remains unchanged. However, the matter now possesses very little interest; since a belief in their virtue is no longer entertained.

*Symptoms which they produce.*—Concretions in the alimentary canal, if retained, give rise to urgent vomiting; and to violent gastrodynia, dyspepsia, colic, constipation, and death. From the obstruction which they produce, we have all the symptoms of enteritis, or of colic, or of strangulated hernia. The treatment, whether the nature of the concretion be known or not, is the same as for colic or enteritis: but, as I said before,<sup>c</sup> it is well to ascertain the state of the rectum. By passing a clyster up the rectum, we have the means of learning whether the obstruction is situated there. Sometimes these concretions have reached the rectum, before they have been stopped.

## CHAPTER VIII.

### CHOLERA.

#### SECTION I.—ENGLISH CHOLERA.

*Symptoms.*—Having described gastro-intestinal concretions,<sup>d</sup> the diseases which I shall now proceed to consider, will all be affections both of the stomach and intestines; and the first which I shall mention is “cholera.” This disease is characterized by a sudden attack of bilious vomiting and purging. At first the discharge is sometimes thin and watery; and has been called “white vomit;” but very soon pure bile comes away;—in fact, unless there be a discharge of bile, it is not cholera. Besides this discharge of bile upwards and downwards, the disease is marked by severe pain in the abdomen; with very severe spasms of the abdominal muscles, of the calves of the legs, and (in very bad cases) even of the neck and back. There is no rigidity (constant spasm), as in tetanus;<sup>e</sup> but violent contraction alternating with relaxation, and drawing the muscles up in lumps. There

<sup>a</sup> About two hundred and sixty pounds sterling.

<sup>b</sup> A coin so called from being struck by dukes; and (when in silver) worth about four shillings and sixpence.

<sup>c</sup> See Page 923.

<sup>e</sup> From χολη, *bile*; and ρεω, *to flow*.

<sup>d</sup> See Page 932.

<sup>f</sup> See Page 628.

is great anxiety and great debility; burning heat, generally at the pit of the stomach; and—as may easily be supposed, from such a quantity of bile being poured forth—there is thirst and headache. These are the symptoms which we see, every autumn, in this country.<sup>a</sup> At last, however, from this violent pain, and from this profuse discharge, the body becomes cold; great faintness is felt; perhaps there is actual syncope; the patient sinks; loses his power; becomes excessively weak; and then every thing occurs exactly as if hæmorrhage had taken place. General convulsions come on; the spasm ceases; and the patient dies, as if he had lost an immense quantity of blood.

*Duration.*—This affection may last only a few hours, or it may last many days. Every body must have seen it seize persons early in the morning; and the persons so seized be dead in the middle of the day. If it subside, it may possibly be followed by inflammation. I have frequently seen gastro-enteritis take place, after the discharge had entirely ceased.

*Nature of the Dejections.*—The bile is generally found to be very acrid; and the vomiting and purging sometimes alternate; so that the more the patient vomits, the less he is purged; and *vice versâ*. Besides the bile discharged, there is usually a great secretion of another fluid;—no doubt, from the stomach and intestines. The same state may arise, occasionally, from an overflow of the secretion of the mucous membrane of the stomach and intestines.

*Causes.*—Intermittent and remittent fevers,<sup>b</sup> and dysentery,<sup>c</sup> in hot climates, very frequently begin as cholera;—I might say, perhaps, *with* cholera. The disease is common in hot climates; and in mild climates in hot weather. Cholera is particularly induced by sudden cold, after long-continued heat;—just the same as inflammation.<sup>d</sup> It is observed, that occasional falls of rain are particularly followed by cholera, in hot seasons, and in hot climates. Dr. Macculloch ascribes this disease to malaria;<sup>e</sup> and probably that is one of the causes; but various things will excite it. Violent passion,—violent emotion of the mind, will cause it. From the latter circumstance, people often vomit or are purged, and sometimes both; and the discharge will be green;—so that cholera is one effect of violent grief. Some persons have this from certain ingesta. Any acrid substance may induce vomiting, or purging, or both; and in this case the discharge may be green; and therefore the affection may be cholera.

*Treatment.*—The mode of treating this affection is, in the first place, to give plenty of chicken-broth, or any other diluent; so as to dilute the acrid bile, which produces such unpleasant effects on the stomach and intestines. We should also exhibit large doses of opium; either in the tincture, or in a solid form. Perhaps the latter would stay best on the stomach. It may be necessary, from the extreme weakness, to give brandy and other stimuli; and to have recourse to the hot-bath. The greater number of cases of cholera that we see, will do well if we give the patient warm diluents;—so as to dilute the bile, and assist nature to discharge it with as little irritation as possible to the stomach and intestines. But it is nevertheless advisable to lessen the disease, at the same time, by exhibiting full doses of laudanum. When the patient is weak, it may be necessary to have recourse to stimuli;—just as in the case of hæmorrhage.<sup>f</sup> Should the disease chiefly consist of vomiting, it may be desirable to send the bile downwards; and calomel will then be the best medicine. It stays better on the stomach than any thing else. An injection may be found very useful. If the case be taken in time, and this mode of treatment adopted, it is very rare for patients to die. We have carefully to examine whether there is any congestion in the head, or any inflammation. After a time, these are very likely to occur; and it is necessary to treat them as we should in any other circumstances. After the disease, it may be necessary to give tonics, and to support the strength; or inflammation may come on; and then it may be necessary to bleed. Sometimes, after the affection has declined, the diarrhœa continues; and

<sup>a</sup> England.

<sup>c</sup> See Page 920.

<sup>e</sup> See Note (a) to Page 265.

<sup>b</sup> See Page 333.

<sup>d</sup> See Page 113.

<sup>f</sup> See Page 140.

it may be necessary to check it in the usual way. But it is requisite to ascertain whether it is accompanied by inflammation or not; for it very frequently is.

This is cholera,—properly so called. That disease which has so unfortunately received the same name, and respecting which so much has lately been said, comes next under our consideration.

[Before proceeding to this, however, it will be proper to say a few words upon a form of cholera frequently met with in this country, and known under the title of

*Cholera Infantum*.—This disease is said to be almost peculiar to the climate of the United States, and is one of the most fatal to which children in our large cities are exposed, during the summer months.

The disease sometimes commences with diarrhœa, soon followed by irritability of stomach; or the vomiting and purging may come on simultaneously at the outset. The discharges from the bowels are not uniform, but their predominant character is that of a colourless, and nearly inodorous fluid, mixed with mucus. The pulse is usually frequent, the skin of the head and abdomen hot, whilst the extremities are of the natural temperature, and in severe cases, cool or decidedly cold. The thirst is excessive, and towards evening there is commonly a decided exacerbation of fever. There is often considerable abdominal pain.

Sometimes the attack is so violent, that death takes place in 24 hours; but this is unusual. Commonly, its course is much more prolonged. Emaciation takes place rapidly, and goes on to such an extent, that ultimately the skin, in some cases, hangs in folds. The cheeks fall in, the eyes become sunken, the nose sharp, and the skin of the forehead tight, as if bound to the bone. The mind and senses become obtuse, so that the child lies unmoved by ordinary impressions, and will even allow flies to collect on the face without being disturbed. Sometimes the brain is affected at an early stage, as shown by the occurrence of stupor or even delirium.

In the latter stage also, of protracted cases, the abdomen becomes tumid, the tongue aphthous, and the feet œdematous.

On examination after death, it is said that the liver is generally enlarged, and sometimes to a great extent. Evidences of inflammation are commonly met with in the mucous membrane of the bowels, particularly of the small intestines and stomach. The rest of the abdominal viscera as well as those of the chest are usually healthy. Serous effusions in the ventricles of the brain have been met with in protracted cases.

This disease prevails during the summer months, declining upon the approach of cool weather. In this section of country, the months of July and August are those in which its greatest ravages are committed. Farther south, the period of its prevalence is more extended, commencing, it is said, as early as April or May, and extending even to November. Not only is great heat a principal element of its production, but also a confined and vitiated atmosphere. This is shown by the fact that the disease is principally met with in the larger cities, and especially in their most crowded portions, and amongst the poorer classes, inhabiting narrow lanes and alleys. Sometimes, however, the disease is met with in the country. The subjects of its attacks are infants during the period of the first dentition. Of course, it is scarcely necessary to observe that improper aliment or other irritating conditions may prove exciting causes, when the system is already predisposed by the presence of a high temperature and a vitiated atmosphere. That it is altogether unconnected with the malaria which gives rise to intermittents, is sufficiently evident from the fact, that it is rare in those districts where intermittents and remittents are most rife, and on the contrary commits its greatest ravages in large cities, where the diseases just mentioned are but little known as indigenous productions.

Our great reliance in the treatment of this complaint is calomel, in small and frequently repeated doses. The eighth or even the twelfth of a grain mixed with gum arabic or sugar, and given every hour, is most effectual in controlling the irritability of the stomach, and allaying the intestinal irritation. Under its use the stools become less frequent, and of a dark green colour. When the frequency of

the discharges has been thus controlled, and their character altered, the calomel may be given less frequently or omitted altogether for a time, and again resumed if necessary. At the same time, the skin should be operated on by the daily use of a warm bath, or by immersing the lower extremities in warm water, rendered stimulating if necessary, by salt or mustard. When the skin is hot and dry, and the abdomen tender, leeches should be applied to the epigastrium; or if the head is hot, with a tendency to stupor or wandering, they should be applied behind the ears. Anodyne injections from time to time may be called for, to relieve the frequency and pain of the discharges. Cool mucilaginous drinks should be freely given, and when the patient has been weaned, the diet should consist of arrow-root or some analogous article.

It has been already stated that small doses of calomel are our chief reliance. Sometimes, however, it is advisable to combine it with chalk; or we may prescribe the *Hydrargyrum cum creta*. Should the frequent watery discharges continue, notwithstanding these measures, we may combine the mercurial preparation with sugar of lead and ipecacuanha in small quantities.

By these measures, combined with the command of free ventilation, cleanliness, and exercise in the open air, we may generally effect a cure, especially where the patient can be removed from the influence of those causes which have given rise to the disease. The mere removal to the country indeed, will often arrest the disease. When this cannot be commanded, the disorder, though arrested for a time, will often recur and finally assume a chronic form, in which the treatment is much the same as in chronic diarrhœa. Here, besides the use of the ordinary alkaline and astringent remedies, it is said that a few drops of the spirits of turpentine given three or four times a day, has sometimes been found eminently serviceable. [T. S.]

## SECTION II.—EPIDEMIC CHOLERA.

In 1817, a disease appeared in India, in some respects like English cholera;—so far as there is a discharge upwards and downwards, severe pain in the abdomen, cramps of the extremities, and at length of the whole body, with great exhaustion.

*Impropriety of the Term "Cholera."*—From its resemblance, in the particulars just mentioned, to the disease last described,<sup>a</sup> it was unfortunately called "cholera morbus;" but there is this decided difference in the two affections;—that in what we understand (or did understand) by "cholera," the motions are all bilious; but in this the motions have no bile in them whatever, but are perfectly white and watery. On this account, if it were necessary to give this disease a name borrowed from another, it would be better to call it "leucorrhœa"<sup>b</sup> than "cholera."

*Symptoms, as they appeared in India.*—In the disease which broke out in India, the first symptoms were languor, uneasiness at the stomach, nausea, and common diarrhœa; and then, all at once,—about three or four o'clock in the morning,—violent vomiting and purging occurred; though, occasionally, these took place without any premonitory symptoms. At the same time, or very soon afterwards, excessively severe spasms were felt in the extremities, and in the abdominal muscles; so as not only to make the patient exclaim with agony, but sometimes to make it necessary to call in the aid of several persons to hold him. The countenance, in a short time, became ghastly; the skin shrivelled; the features contracted and elongated; the eyes a little suffused, lightly tinged with red, and sunk in the sockets; the lips purple, or of a black cast; the base of the eyelids likewise purple; the skin and the nails blue; and the fingers not only shrunk, but shrivelled;—exactly like the hands of an old washerwoman. At the same time, there was extreme thirst; with a great sensation of heat in the throat. The temperature of the whole body was excessively low; the tongue and the breath were cold; sometimes the tongue was quite clean, and of the colour of lead; but occasionally it was white, and had a tough, or (as it has

<sup>a</sup> See Page 935.

<sup>b</sup> From λευκος, *white*; and ρεω, *to flow*.

been described) a leathery coat; and occasionally it was covered with sordes, but by no means always. The pulse became exceedingly weak, and exceedingly quick; and at last it could not be felt at all in the wrists, though it might still be perceived at the heart. Extreme restlessness took place; so that the patient could scarcely bear the bed-clothes, and endeavoured to toss them off. The breathing, like the pulse, became more rapid than in health. It was found that, in the expirations, only one-third of the usual quantity of carbonic acid was given off. The blood that was taken was found to be thick;—some say pitchy and uncoagulable. The venous and arterial blood were equally black; and, in the worst cases, the blood would not flow at all. It was likewise observed that no urine was discharged. Deafness was noticed as a frequent symptom; and also tenesmus.

Occasionally, however, there was scarcely any vomiting, but extreme debility; together with extreme loss of bulk, shrinking of the body, the corrugated state of the fingers, and the violent spasms. These cases were considered to be worse than those in which vomiting and purging took place. This disease differs from our cholera, in there being danger where there are scarcely any evacuations;—the danger of the disease not depending upon, and not being in proportion to, the loss of the substance of the body. Sometimes it is said that, in addition to there being neither vomiting nor purging, no spasm was felt; and this was considered still worse. The patient was said to be “struck with death;” his pulse became imperceptible; and death very soon closed the scene.

*Irregularity in the occurrence of the Symptoms.*—There was great irregularity as to the occurrence of these things. Patients sometimes vomited and were purged, before they experienced spasms; and sometimes spasms occurred at the onset of the disease. Occasionally, blueness of the nose and about the eyelids was not observed; and sometimes there was no corrugation. There was by no means uniformity in the symptoms.

*Precursors of Death.*—Before death, it was very usual to find the spasms, the vomiting, and the purging cease; and for the patient to lie perfectly still, with the loss of the vigour of his mind, but with a perfect preservation of his reason. He would be conscious of all around him, but wish not to be disturbed; and he would take no nourishment. He would remain tranquil, as if waiting for the moment of death; not only would the pulse at the wrist be still, but sometimes (it is said) the action of the heart could not be felt. Whether the ear was employed to ascertain whether the heart acted or not, I do not know. I presume it is common enough, in different diseases, for the pulse not to be felt, when the heart still continues to beat. Before death, it was occasionally noticed that the temperature would return; and hopes of recovery were sometimes entertained; but these were, for the most part, unfounded; for the patient presently sunk. It was likewise observed that, after this extreme exhaustion, the face would sometimes become flushed, the temporal arteries become distended and throb, and the patient lie in a somewhat delirious or comatose state;—much in the condition of a person in typhus-fever. The voice was weak and very peculiar. The duration of the disease was sometimes only a couple of hours; and sometimes it would not destroy life for the greater part of a day.

*Morbid Appearances.*—After death, an immense quantity of white turbid fluid, with flakes of a very white substance, were found in the stomach and in the intestines; while no fluid whatever was found in the urinary bladder, and that organ was contracted to the smallest possible size. These were general occurrences. It was usual for neither feces nor bile to be found in the alimentary canal; but the gall-bladder generally (not always) was found full, and sometimes it was remarkably distended;—so that there was no want of bile, but none passed into the alimentary canal. The veins were usually found greatly distended with blood; so that the hepatic, intestinal, and mesenteric veins, were remarkably distended; but those of the spleen were not quite so full. Congestion also occurred very frequently in the lungs and in the head. Sometimes there was a rosiness of the external surface of the alimentary canal; and sometimes of the *internal* surface. There was usually,

too, a great congestion of blood in the heart itself. The abdominal muscles were found, by Dr. Davy, to be flabby and red; but, of course, not inflamed. The urinary bladder—although containing no urine, and being so greatly contracted—had generally a sort of whitish mucus, with flakes, upon the inner surface. After death, one very remarkable phenomenon presented itself;—the temperature of the body was higher than during life; so that a very high degree of heat was found, on plunging the hand into the body. Another very remarkable circumstance is mentioned:—the occurrence of a twitching of the different muscles of the body, after the person was completely dead. The fingers, the toes, and every part of the face, were seen to move. Observations of this description were made on two subjects;—the one a Caffre, and the other a Malay. The former died twenty hours after the first seizure;—the complaint baffling the most powerful remedies. In fifteen minutes after he expired, the fingers of the left hand were observed to move; then the muscles of the inside of the left arm were contracted in a convulsive manner; and the like motions were slowly propagated upwards to the pectoral muscles. The muscles of the calves of the legs contracted in like manner;—bundles of their fibres being drawn together, in a tremulous knot. The muscles of the inside of the leg and thigh were forcibly contracted, in a vermicular manner. The muscles of the face and lower jaw were similarly affected; and, finally, those of the right arm and right pectoral muscle. These motions increased, in extent and activity, for ten minutes; after which they gradually declined, and ceased twenty minutes after they began. With regard to the Malay, about fifteen minutes after he expired, the toes began to move in various directions; and the feet were made to approach each other. Muscular contractions were speedily propagated upwards, along the inside of the legs and thighs. The thighs were turned slowly inwards, so as to approach each other, and again outwards;—the whole of the lower extremities moving on the heels, as on pivots. These motions proceeded upwards;—producing a quivering in the muscles. In five minutes, the upper extremities began to be similarly affected. The fingers were extended, and often rigidly bent inwards; and pronation and supination of the hand were steadily, though slowly, performed. The same quiverings were observable as in the lower extremities; and extended to the “*pectoralis major*” muscles, and the superior margin of the “*latissimus dorsi*.” The muscles of the face moved; and the head was observed to shake. The total duration of these appearances, was half an hour. By moving or pricking the arms or limbs, these contractions were rendered stronger, and were again renewed where they had ceased.

This is the account which has been given by various writers, who witnessed the disease in India. I will now describe the disease which prevailed in London.

*Symptoms, as they appeared in London.*—Among the patients whom I saw, there was great variety as to the mode of attack; and as to the order of the symptoms after the disease had begun. With regard to the first point, some persons were attacked suddenly; while others had diarrhoea for some time previously. Those who were suddenly attacked, were generally seized early in the morning, after going to bed perfectly well; and discharged, by vomiting and purging, a turbid whitish fluid, containing white flakes. There was violent pain in the abdomen; violent pain in the extremities; and dreadful cramps in the fingers, toes, arms, and legs. In two or three hours from the moment of the attack, I have seen the eyes sunk in the sockets; blueness round the base of the eyes; blueness of the nails; in some cases, blueness somewhere upon the extremities; in one case, blueness of the whole body; no discharge of urine; intense thirst; a great sensation of heat within; extreme restlessness; the tongue of a colour like lead; and (in the case in which the body was blue all over) covered with a white and leathery crust; a very feeble pulse; and, at last, no pulse whatever in the extremities, although it could be felt at the heart. The pulse and the respiration were very rapid. I have counted the respirations at thirty-six in a minute. There has been a great fall of temperature; so that the hands, the tongue, and the breath (as it came from the body) were cold. On passing a thermometer into the mouth, I have found it as low as *eighty-four*

degrees;—ranging only, at any rate, between *eighty* and *ninety* degrees. There has been a cold sweat on the extremities; and then, at last, the patient would remain free from restlessness, pain, or vomiting; and would lie perfectly still, conscious of every thing, but with a desire not to make the least exertion,—apparently tranquil, and waiting for his dissolution. Then, before death, I have noticed the temperature rise,—the coldness cease; and after death, the temperature has risen still more. In the case where there was such great blueness,<sup>a</sup> no sooner had the patient expired, than the blueness was diminished. I did not observe whether it diminished before death, but I noticed it immediately afterwards; and, in an hour, there was nothing of the colour to be seen. There was a twitching of the muscles; so that one finger, after death, would be drawn in, and then another; and the lower jaw would move up and down; and we might see a quivering of the muscles inside the thighs. The voice was weak; and there was a great peculiarity in it.

*Morbid Appearances.*—After death, the stomach and intestines were usually found filled with a white fluid, containing white flakes. There were various appearances of the alimentary canal, both internally and externally. Sometimes it was rosy, and sometimes pale. The urinary bladder was empty, and exceedingly contracted. The congestion in the venous system was very great. The mesenteric veins were full; and the “*venæ cavæ*” appeared distended to the utmost. They looked like a bell-rope in a drawing-room. The heart was observed to be full; and the blood, both in the ventricles and auricles, was grumous,—half coagulated. There was sometimes congestion in the head; and sometimes in the lungs.

*Identity of the Disease in India and London.*—No one possessed of common sense can doubt, for a moment, that the disease which occurred in India, and that which we have seen here in England, are precisely the same. I should think no one can doubt, that it is different from the disease commonly called “*cholera*,” which is marked by a discharge of bile, and in which the danger is in proportion to the extent of the evacuations. It cannot be said that this disease is only a severe form of common cholera; because the mildest cases are not at all like common cholera, they are not characterized by a discharge of bile. If it were cholera, only very severe, the mild cases ought to be equal to the very severe ones of the common cholera of this country.

*Is it a New Disease?*—Again: it has been said that this disease is not only essentially common cholera, but that it is a disease we had all seen before. If it had previously occurred in London, I think that, from being connected with a large institution,<sup>c</sup> I should have seen it; but I certainly never saw an affection that bore the least analogy to it. It would not be more absurd to say, that measles and common brouchitis are the same, because in both there are certain morbid appearances in the air-passages; than it is to say that, because there is vomiting and purging in this disease as well as in common cholera, they are the same. A variety of diseases of the skin, which are distinct from each other, have an appearance in common; and measles, scarlet-fever, and other affections, were formerly all jumbled together.<sup>d</sup> No diagnosis was made between them;—simply because there was redness of the skin.

The cholera which Celsus and Sydenham described, is very different from this affection. Sydenham says it prevails at the end of summer and during the autumn, as regularly as vegetation comes in spring; whereas this disease occurs at all seasons, and has no connection whatever with heat. Sydenham describes it as a discharge of *bile*; and not of the peculiar fluid which we see in this affection. I have conversed with practitioners older than myself,—with men of the greatest experience; and they declare that they have never met with such a disease before.

*History of the Disease.*—It was thought, in India, that the natives suffered from it more than the Europeans. Thousands of natives perished near Bombay; while of the Europeans, who had good food and good clothing, six only were affected. It was found to attack those who had the worst diet, who were the worst clothed,

<sup>a</sup> See Page 940.

<sup>c</sup> St. Thomas's Hospital.

<sup>b</sup> See Page 935.

<sup>d</sup> See Page 387.

and were worst off in all respects. It was found to prevail at all temperatures, and all seasons;—in *healthy* and in *unhealthy* situations; both in *dry* and in *moist* places. It prevailed in spite of the monsoons; and not only in every direction of the wind, but in all hydrometric states of the atmosphere. There was great doubt whether it was contagious or not. Some thought it proceeded where there was no communication, just as well as when there was. It was found suddenly to stop without any apparent reason, and then to go on again;—to pass from one district to another, as regularly as any other disease would; and then, as soon as it ceased in one place, it would begin in another. It was said, that it broke out in the Mauritius, three thousand miles from the place where it had prevailed; but it was after a vessel had arrived from that spot. On reading the accounts of the disease as it appeared in different countries, we find a mass of evidence tending to prove that it is contagious; and then we find a mass of doubtful circumstances, which unsettle our minds again.

I need not say that it turned, at last, towards Europe; and proceeded, pursuing a northwesterly direction, till at last it reached this country; and, with all the observations that could be made, it is still a matter of doubt whether it is contagious or not. The particulars observed here and on the continent, however, perfectly agreed with what I have stated; namely, that the poor were affected much more than the rich; and that those who were the worst fed, clothed, and lodged, all suffered in the greatest degree. We had a striking example of this, in contrasting its ravages in London, with those it made in Paris. Here the greater part of the people are well fed;—better fed than in any other part of the world. They eat more flesh; and that flesh is of such a quality, as is scarcely to be found in any other country. Besides this, they are better clothed, and more comfortable; and, instead of trashy wines, they have good sound ale and porter, and malt-liquor of all kinds. But in Paris the air is bad; the people have very little water; and the water, for the purposes of consumption, is very bad. The inhabitants are crowded together,—I know not how many families in a house,—with little ventilation. The streets are narrow; and, together with this, the houses are dirty. The population live upon what we Englishmen call trash;—not roast beef and mutton; but all sorts of dishes made up of bread and vegetables, with a little meat boiled in water to colour it, or to give it a flavour; and they drink, not good beer, but thin wine; and we all know that this disease has committed infinitely more ravages,—done infinitely more mischief there, than it has here. This completely accords with what was observed in India.

*Is it Contagious?*—With regard to contagion, we have in this country many observations, which tend to show that the disease is contagious; and then, again, we have cases occurring, where we cannot imagine communication could have taken place. In the “Medical Gazette” (Volume 10, Page 31<sup>a</sup>), reference is made to a work by Dr. Hazlewood; in which several facts are mentioned, which go to show the contagiousness of the disease; and these, together with facts which I have noticed myself, have created a strong suspicion in my mind, that it is contagious. But while I am inclined to believe that to be the case, yet I am also satisfied that it will spread without contagion at all. It may spread, independently of contagion; but if the disease do occur in an individual, I cannot but think that that individual may communicate it to another. Of course we shall find a large number of exceptions to its spreading, where we might, *à priori*, expect that it *would* spread. The disease has great difficulty in attacking those who are in good health, and well off; and in this respect it differs from syphilis, itch, and small-pox; and therefore, though thousands may be exposed to the contagion of the disease (if contagion really exist), yet they will be almost sure to escape. This must be taken into consideration, when we consider whether the disease is contagious or not. If a number of persons be exposed to it, and escape, yet that is nothing more than we should expect.

<sup>a</sup> No. 227; April 7, 1832.

*Mortality.*—It was observed, in India, that much good was done by medical treatment. It is said that, at Bombay,—where there were from two hundred thousand to two hundred and twenty thousand inhabitants,—there were fifteen thousand nine hundred and forty-five cases. Of these, one thousand two hundred and ninety-four took no medicine, and all died; but where medicine was employed, the deaths were much reduced. It was supposed there,—at least, it was so stated in books at the time,—that by the administration of large doses of calomel and opium, occasional bleeding, and the hot-bath, great good was effected; and that many lives were lived. Some persons gave calomel in *small* doses; and gave some scruples, with a drachm of laudanum;—altering this according to circumstances. Others bled their patients, when they could get blood to come; and it was said that that treatment, also, was very successful. Some practitioners adopted both plans. Some strongly recommended the use of magnesia, and other absorbents. Indeed, one celebrated writer says, that magnesia and absorbent specifics have saved thousands of lives. Such was the treatment there; and the success, as I have stated, was considered to be very great.

*Liability of Spirit Drinkers.*—It was well ascertained in London, that not only those who were badly off, and in bad health from some other disease, but those who were in the habit of drinking spirits, were very liable to the disease. I do not know that such an observation was made in India; but I presume that drunkards there suffered,—the same as here. In Europe, however, it is an undoubted fact, that that portion of the lower orders who had every thing calculated to keep them in good health, but who indulged in spirit-drinking, were sure to suffer; and this has been observed with regard to other diseases. However well persons may be off, yet if their body be enfeebled, they are rendered increasingly liable to the disease.

*Treatment.*—As respects this country, I cannot but think that if all the patients had been left alone, the mortality would have been much the same as it has been. If all the persons attacked with cholera had been put into warm beds, made comfortable, and left alone,—although many would have died who have been saved,—yet, on the whole, I think the mortality would not have been greater than after all that has been done; for we are not in the least more informed as to the proper remedies, than we were when the first case of cholera occurred;—we have not been instructed, in the least, by those who have had the disease to treat. Some say that they have cured the disease by bleeding; others by calomel; others by opium; and others, again, say that opium does harm. No doubt many poor creatures died uncomfortably, who would have died tranquilly if nothing had been done to them. Some were placed in hot war, or in hot air, and had opium and calomel, and other stimulants; which, altogether, were more than their system would bear, and more than would have been borne if they had been so treated even in perfect health.

I am sorry to say that, of the cases I had to treat, the patients nearly all died. I tried two or three sorts of treatment. Some had opium and calomel, in large and full doses; but they died. Hot air was applied externally; and I got two to *breathe* hot air. I had a tube passed through boiling water; so that they might inhale hot air. It was found vain to attempt to warm people by hot air applied *externally*. They were nearly as cold as before;—we could not raise their temperature; and therefore I thought of making them breathe hot air; but both patients died, about the period that death usually takes place. It was said that saline treatment was likely to be of use; and I accordingly tried it in some patients. At first I exhibited half a drachm of sesquicarbonate of soda, every hour; and, thinking that might not be quite enough, I exhibited a drachm: in one patient at St. Thomas's Hospital, I ordered an injection containing an ounce of the same remedy; but the greater part of it came away, and the patient died. Hot air was used in this case, as well as in the others.

*Condition of the Blood.*—This leads me speak of the chemical qualities of the blood, and of the discharge from the alimentary canal. It has been said that the

contents of the latter were *alkaline*; but I examined that point, in several cases where no alkali had been taken: and so far from the observation being correct, I found them exceedingly *acid*. In the case of a man who was blue from head to foot, and who had twitches after death,<sup>a</sup> the contents of the stomach were exceedingly acid; but the intestinal matters were less and less so, as we went downwards, till we got to the large intestines; and there they were natural. In the patient who took large doses of the carbonate of soda, and had an ounce thrown up,<sup>b</sup> the contents of the stomach were then only neutral, while those of the intestines were acid. When we came to the rectum, where some of the carbonate of soda that had been injected still remained, they were alkaline. The cases that I have examined, have not been numerous; but in all of them the contents have been principally acid; and in no case were they alkaline, except in the one I have just mentioned.

Dr. O'Shaughnessy has published some observations and experiments on this subject. He says:—"The summary of my experiments may be described as denoting a great, but variable deficiency of water in the blood, in four malignant cholera cases; a total absence of carbonate of soda in two of them; its occurrence in an almost infinitesimally small proportion in one; and a remarkable diminution of the other saline ingredients in all." It would appear, from these four cases, that there is less serum in the blood; and therefore we see why it is thicker in this disease than in health; and that there are also less saline ingredients in it. He also says:—"In the dejections passed by one of the patients whose blood was analyzed, we found a preponderance of alkali; and we recovered the other saline matters deficient in the blood." Thus he supposes that the blood loses its saline particles; that they are discharged into the intestines; and that we find them there, in the same proportion as the blood has lost them. But although that may be the case, it is not clear that the dejections are of an alkaline quality;—that is to say, that there is an excess of alkali in them.

I really can say nothing satisfactory with regard to the treatment; but I know that patients feel intense heat within, and intense thirst; and that they find great comfort from cold drinks. I understand that, in Vienna, the custom was to allow ice; which the patients took with great avidity, and derived great comfort from it.

## CHAPTER IX.

### DISORDER OF THE DIGESTIVE ORGANS.

THE disease which I shall now describe, is commonly called "indigestion;" but I would rather speak of it under the denomination of "disorder of the digestive organs at large;" because "indigestion" applies to affections simply of the stomach; whereas this affection implicates the intestines as well as the stomach; and, indeed, all the organs concerned, not only in chylicification, but also in excretion.

*Definition.*—"Indigestion" is usually termed in medicine "dyspepsia;" and is sometimes mentioned under the name of "*apepsia*;"—the one meaning "*difficult digestion*" (from *δυσ*, with *difficulty*; and *πεπω*, to *concoct*); and the other "*no digestion*" at all (from *α*, *privative*; and *πεπω*, to *concoct*). However, these all mean precisely the same thing. We are now, therefore, to consider that derangement of the digestive organs, which is generally attended with indigestion; but many of the symptoms of which take place *without* indigestion. Many persons will digest very well; and yet, when they have no food in the stomach, they are filled with wind. But this ceases on food being taken.

<sup>a</sup> See Pages 940 and 941.

<sup>b</sup> See the previous Paragraph.

*Sympathetic Derangement.*—If any organ in the body suffer severely, the stomach is very much disposed to sympathize with it. The stomach, the heart, and the head, are particularly affected when any material derangement occurs in the frame,—the stomach more particularly, perhaps, than either of the others; and the intestines generally become more or less affected at the same time. We know that, in all acute diseases,—in all violent accidents, the stomach feels the shock. There is anorexia (loss of appetite), frequently nausea and vomiting, and either costiveness or purging. The fæces generally become depraved in their quality; uneasiness is usually felt in the stomach or intestines; and there is, perhaps, even pain and tenderness. Very frequently, the patient is rendered more uncomfortable by the sympathetic disturbance of the stomach and bowels, than by the original affection itself. In chronic diseases of the heart, liver, and lungs, for instance, the stomach and intestines are most materially affected. But besides these effects, mere *sympathetic* occurrences, from the derangement of other organs,—we have these parts deranged *originally*.

## SECTION I.—SYMPTOMS.

I will now proceed to consider all the symptoms, which characterize those affections which pass, every day, under the name of “derangement of the digestive organs.”

*Anorexia.*—In the first place, loss of appetite is a very common symptom; and this is called, in medical language, “anorexia.” Sometimes, however, the appetite is not *lost*; it is only *irregular*;—the patient being able to eat well one day, though he cannot eat another. Sometimes the anorexia amounts to loathing;—the patient not only cannot eat, but the idea of it disgusts him.

*Pica.*—Sometimes the appetite is not simply *deficient*, but is *depraved*.<sup>a</sup> This is particularly seen in females; and is called “pica” (*a magpie*;—an animal said to be subject to this complaint). Sometimes young ladies long for chalk, cinders, or sand; and they will bite glass,—munch it; and, when it is small enough, they will swallow some of it. I saw a lady, who ate *brown* paper; she longed for something to eat,—for something that she had never eaten before; but she could not tell what;—nor could I. I have heard of cases where the patient longed for raw flesh, and even for *live* flesh; so that some have eaten live kittens and rats. This is an absolute fact. In the same way, some have been known to long for the contents of snufflers; and even for manure. A case is described of a man who ate a live pig,—leaving the intestines; but, after a little while, he ate them also. There is a case described, at full length, in a German work, of a boy who had such a longing for lime, that he ate all the mortar he could pick out of the wall; and, being well horsewhipped for it, he then commenced on a *neighbour's* wall. In order to prevent this, however, the neighbour smeared the wall with a decoction of worm-wood, and the boy could no longer relish it; but he then went to the kennel in the street, and sucked up the sand. He had a desire for something dirty. After this he got to some quick lime; and was forced to drink a large quantity of water, to extinguish his thirst. The mucous membrane within, had a distaste for what is called “good food;” but, in other respects, he was quite well. I recollect having read of a girl, and also of a student at Leyden, who always ate spiders when they could get them; and no harm arose from it. I have read of a man who disliked bread, and never ate it; but he was seized with a quartan ague, and then ate a large quantity. He recovered from the ague; and the disgust towards bread returned. This disease occurs in young women (even moral ones) who do not menstruate well;—as I mentioned when speaking of chlorosis;<sup>b</sup> and many pregnant women have some strange longing of this description. Every one must have met with instances of women longing for what it was difficult to get;—longing for things out

<sup>a</sup> See Page 219.

<sup>b</sup> See Pages 218 and 221.

of season. There was one who longed for a bit of the priest's sleeve, and contrived to get at it and bite it;—not caring for his excommunication. I could relate cases, almost without end, of this description. One dipped her bread in a tar-tub. I never met with these extreme cases; but every one must have read of instances of this nature.

*Bulimia.*—Sometimes, however, the appetite is *excessive*; so that people will eat an immense quantity. This is called “bulimia.”<sup>a</sup> I mentioned, when speaking of fever, that this has sometimes occurred as a temporary symptom of another disease.<sup>b</sup> People will eat many pounds of meat and bread in the course of a day.

*Thirst and Foul Tongue.*—Persons labouring under this affection, frequently complain of intense thirst; and their tongue is foul, and covered with a yellow or a creamy mucus. Sometimes it is white, dry, and brown; but, whatever appearance it has, it is worst in the morning. It is frequently red at the same time,—either at the tip or at the edges. Sometimes it is the papillæ only that are red. They appear separate;—like granules of cayenne-pepper. Sometimes the tongue is red all over; and it may be moist, dry, glazed, or cracked.

*Fetid Breath.*—There is frequently fetor of the breath. Sometimes the smell is sour;—sometimes it gives one the idea of sour flesh; sometimes it is like cabbage-water; and occasionally it is absolutely fæcal;—so that it is impossible to stand near the patient. I mentioned that the most horrid kind of fetid breath, frequently arises from a depraved secretion within the tonsils.<sup>c</sup> Of course we may have a diseased odour of the breath, from other circumstances than any of these. It will arise from a diseased bone; and sometimes even from carious teeth. This is not so disagreeable to others; but it is very unpleasant to the patient himself,—from there being a bad taste in his mouth. Sometimes the taste is bitter; and sometimes, they say, it is particularly offensive.

*Eruclatians.*—Eruclatians are very common in this affection; and these may be either simple or fetid. Those which are inodorous, are generally experienced when the stomach is empty; and probably arise from a secretion of air by the surface of the stomach; but those which are fetid arise, I presume, from the contents of the stomach undergoing a certain degree of fermentation, or sometimes from the patient being costive. It appears that a portion of the fæcal odour, if not of the fæces, is absorbed; for some persons who are exceedingly costive, have very fetid eruclatians; which are removed by regulating their bowels. In some persons, it is only when certain articles are taken, that the breath becomes offensive. Sulphuretted hydrogen appears to be given off from the substances in question.

*Nausea and Vomiting.*—Besides these affections, the stomach sometimes experiences attacks of nausea and vomiting. Some vomit only the food they take; others vomit a viscid secretion. Some vomit more or less constantly; and some vomit only in the morning;—and, in the latter case, it usually arises from drinking. When the disease has become very severe, some will vomit on the slightest motion.

It is very common for the mouth to become filled with watery fluid; and often very suddenly. Sometimes the patient's mouth is constantly open. I have seen patients spit a pint a day. Occasionally the fluid is tasteless; but more frequently it is salt, or sour; and occasionally it is very acrid indeed;—containing a large quantity of muriatic acid. I believe it is often felt to be very cold. Patients complain of its coming up, as if it proceeded immediately from a spring.

Independently of this fluid, there is frequently an excessive quantity of viscid mucus; chiefly hanging from the pharynx; and causing a constant desire, on the part of the patient, to hawk it up. Many cases of this description, are mistaken for affections of the air-passages. I was myself, for some time, completely in the dark respecting it;—conceiving that persons had a constant discharge from the air-passages, when they had nothing more than indigestion. The vomiting may either be of simple food which has become exceedingly sour and acrid, or fetid; or it may be of bile; so that we have every variety of vomiting;—just as we have every

<sup>a</sup> From *βου*, *excessive*; and *λιμὸς*, *food*.

<sup>c</sup> See Page 700.

<sup>b</sup> See Page 237.

variety with regard to the appetite, with regard to the appearance of the tongue, and with regard to the eructations.

*Gastrodynia and Pyrosis.*—To descend lower, there is tightness and fulness of the abdomen;—chiefly at the epigastrium, and chiefly after meals. Frequently there is an aching there; and sometimes excessive pain. Occasionally this is experienced only after meals; and occasionally only when the stomach is empty. This pain, if it be unaccompanied with inflammation, passes under the name of “gastrodynia;” and if, with this, there is a flow of fluid into the mouth, the two circumstances together are called “water-brash,” or “pyrosis” (from *πυρωσ*, to burn). The pain is sometimes sudden,—comes on instantly, or at least very rapidly; and is excruciating. It darts back, perhaps, to the spine; and causes the extremities and face to become cold, the pulse to be small, and the surface pale. It passes under the name of “spasm of the stomach.” Very frequently, at the same time, there is a large discharge of flatus through the œsophagus;—flatus which is usually inodorous. This pain frequently runs to the left shoulder, and down the left arm;—like the pain experienced in “angina pectoris.”<sup>a</sup> I have known it run down both arms, up the jaws, and along the teeth. Sudden attacks of this affection, are seen more commonly in women than in men. The pain is not always felt precisely in the situation of the stomach itself; but occasionally in the shoulder-blades, and occasionally in the ribs;—even in those which are not over the stomach; though the pain is dependent on that organ. In my own case, I have occasionally laboured under this pain severely; and I have been able to get rid of it by putting my fingers into my throat, and discharging a quantity of sour stuff. When the pain in the ribs returned again, by making so slight an effort as hardly to be called “vomiting,” but sufficient to discharge a quantity of stuff like bird-lime, I have invariably found the pain go way. If I had not paid attention to the stomach, I could not have believed that the pain arose from that organ. The pain is sometimes felt even at a distance;—in the calves of the legs, for instance. Frequently, when there is much disturbance of the stomach, the legs fall into a state of violent cramp; the most common cause of which, is the presence of acid in the stomach.

*Cardialgia.*—Besides this *spasmodic* pain,—which, for the most part comes on suddenly; or, if it exist constantly, is attended with exacerbations; and is not increased by pressure, there is frequently *inflammatory* pain;—not *gastrodynia*, but *gastritic* pain; so that the stomach is tender on pressure, and all ingesta produce great agony. A sensation of heat is induced in the stomach, and up the throat. In some cases, there is a throbbing of the epigastrium,—a violent pulsation; which no doubt has been mistaken, over and over again, for aneurism; and which patients themselves are inclined to believe is aneurism; because, in this state of things, they are much disposed to despond. This has been called “cardialgia;”<sup>b</sup> and has been referred, by Sauvages, to a morbid sensibility of the part. Dr. Baillie wrote a paper on this subject, in the fourth volume of the “Transactions of the College of Physicians;”<sup>c</sup> in which he stated that he had been consulted, several times, on this affection; which had been supposed to be aneurism; but which he had not found to be so. He opened persons who died from some other disease, while labouring under this; and found nothing morbid. It is a common symptom;—one which I have frequently been consulted upon; but we find no tumour. On pressing the part, we feel the shape as usual; and we find, at the same time, a great depression of spirits; and, more frequently than not, various symptoms of disorder of the digestive organs. On looking over Sauvages, I find he has described it as a dyspeptic symptom; and has referred it to a morbid sensibility of the arterial system of the part. He says it is certain that the gastric arteries and the aorta, although not affected with aneurism, yet, in those who are constantly hypochondriacal and hysterical, acquire an exquisite sensibility, and produce this state. Occasionally the heat is far beyond what I have just mentioned. It is a *burning* pain; and patients usually speak of it as a “burning sensation.” It arises, in most instances, from the quantity of acid produced in the

<sup>a</sup> See Pages 866 and 867.

<sup>b</sup> From *καρδια*, the heart; and *αλγος*, pain.

<sup>c</sup> Page 271.

stomach; and if there be any inflammation of the mucous membrane, the pain will be proportionately severe.

*State of the Bowels.*—The bowels are generally irregular; and, for the most part, they are torpid; but sometimes they are relaxed. In other cases we find an alternation of costiveness and relaxation; so that they are never right. The *feces*, too, are frequently unhealthy. Frequently they are lumpy; but they are of various morbid degrees of consistence, and of various morbid colours; and frequently they are not of their usual smell. Sometimes there is a great want of bile; and sometimes there is even a degree of icterus. From the irritation of the stomach, the urine usually becomes high-coloured; but at other times,—especially when there is a great quantity of wind generated in the stomach itself,—the urine becomes excessive in quantity, and pale;—just as in asthma.<sup>a</sup>

*Headache.*—Other parts of the body, however, suffer as well as the gastro-intestinal, or (as it used to be called) the alimentary canal. There is frequently headache,—either general, or particularly in the forehead; and very frequently it is confined to one part of the forehead,—to one brow. Sometimes it is intermittent; and sometimes absolutely periodical. I have no doubt, however, that occasionally this headach does not arise from the state of the stomach; for disturbance of that organ may be produced by cold, or vexation of mind; and then, when it comes to be very severe, it will make a person sick. On the other hand, it frequently arises from taking into the stomach things which disagree with it. I formerly mentioned how hereditary this description of headache is;<sup>b</sup>—how frequently we see it in fathers and in children;—how frequently it occurs in many members of the same family. Sometimes it will come on at *regular*, and sometimes at *irregular* intervals;—disappearing, perhaps, after a certain number of years. It is so obstinate, that I do not recollect curing a case of it; though I have tried every thing that could be devised.

*Disturbance of the Nervous System.*—Frequently, in this disease, there is confusion of mind. Patients cannot employ themselves as they did before. They cannot read long; and I have known some obliged to give up study altogether. Frequently there is vertigo, heaviness of the head, and sleepiness; but, on the other hand, when the stomach is much deranged, it is common for persons to lie awake;—they find it impossible to go to sleep. There is frequently, too, a ringing in the ears,—“*tinnitus aurium*,” and specks appearing before the eyes,—“*muscæ volitantes*.” There is frequently great sadness,—great depression of spirits. Patients are very restless and fidgety; and sometimes their temper is very irregular; so that we must take care not to say many things which, at other times, we might say with impunity. Voltaire gives special directions to those going to ask a favour of the Prime Minister. He tells us to ascertain (from his *valet de chambre*) whether he has had his bowels opened in the morning;—so much does temper depend upon the alimentary canal.

The heart also sympathizes with the stomach. There is frequently palpitation in these cases; and sometimes an intermittent pulse. Frequently there is nightmare, or terrific dreams. A partial consciousness, and yet an inability to make a voluntary exertion, come on during sleep; but when patients can make an effort, they imagine they get out of this condition. Incubus is a very common symptom. There is frequently, too, a sense of great debility; which is felt particularly at the pit of the stomach. Patients complain of this every day;—they say they feel as if their inside were all gone to decay. Sometimes there is a tremor of the whole body. The skin likewise suffers. It is generally dry and cold; but sometimes it is hot.

Persons sometimes have merely an inability to digest food; and are very well so long as there is no food in the stomach. But true dyspepsia (that is to say, that affection which depends upon the stomach performing its functions improperly; and which is worse after eating, or indeed is only experienced then) is attended with other symptoms. There is loss of appetite, vomiting, distant pain, and the other

<sup>a</sup> See Page 769.

<sup>b</sup> See Page 485.

symptoms which I have mentioned;<sup>a</sup> but we frequently have these without much indigestion. Persons complain of a great sinking at the pit of the stomach; they will also have gastrodynia and pyrosis; and yet they will digest their food well,—have no dyspepsia; although there is derangement of the stomach. They are very well when they take food; and only suffer when the stomach is empty. Some of these things are merely called “indigestion.” Some patients have none of these symptoms; and some may have one or other, or both together. Persons who suffer in this way, frequently become pale and emaciated. They live many years; but are never well. They are not ill enough to die; but their complexion becomes altered.

## SECTION II.—CAUSES.

The causes of all these symptoms, and of all this derangement, may be *beyond* the stomach or intestines;—they themselves being disposed to be perfectly healthy; or, again, the causes may be in those very organs.

*Hernia.*—In the first place, the cause may be in the groin. A hernia will produce all these symptoms. If a person have a rupture, he is sure to be troubled with irregularity of bowels, costiveness, extreme flatulence, and perhaps gastrodynia and indigestion. If the hernia return into the abdomen, these symptoms may all vanish. Any sort of pressure may have the same effect.

*Constipation.*—Obstruction or costiveness, without any fault in the bowels themselves,—costiveness from persons neglecting to relieve their bowels, or any accidental obstruction whatever,—may produce these symptoms. The presence of worms, or any injurious substances which the patient has taken, may give rise to them;—the stomach and bowels themselves being disposed to perform their functions properly, if these mechanical or accidental circumstances were not forced upon them.

*Improper Food.*—Occasionally, these symptoms entirely arise from the individual having taken articles, of which the stomach can make nothing,—which it cannot manage. These ingesta may be altogether improper for any one to take; or the individual may have some particular idiosyncrasy,—peculiarity of constitution. Some persons have a stomach, which can digest things in general very well; but there may be one or two things, which their stomach cannot digest; and if these be taken there is dyspepsia, and some intestinal derangement. We can hardly say that such a person is ill; because the circumstance only occurs when he has taken some particular article of food. I once saw a maid-servant who, whenever she took any kind of fruit, experienced dreadful gastrodynia;—the pain running into the back, and causing a rapid pulse, extreme agony, and cold sweats. She could digest hard salt beef, and her general food; but if she took a strawberry or a gooseberry, she was thrown into the state I have described.

*Excess of Food.*—Of course, an *excessive quantity* of food, will have the same effect as improper ingesta. Nature not only intends us to eat certain things, and not others, but she also intends us to eat a certain quantity;—and therefore, just as a person may have “*diarrhæa crapulosa*,” so they may have “*dyspepsia crapulosa*” (from *κραίπνλα*, *a surfeit*);—the stomach not being in fault, but having more given to it than it ought to have. The author of “*Ecclesiasticus*” says, that “*excess of meats bringeth sickness.*”<sup>b</sup>

<sup>a</sup> See Pages 944 to 949.

<sup>b</sup> “Be not unsatiable in any dainty thing; nor too greedy upon meats. For excess of meats bringeth sickness; and surfeiting will turn into cholera. By surfeiting have many perished; but he that taketh heed, prolongeth his life.”—*Ecclesiasticus*; Chapter 37; Verses 29 to 31. “*Ecclesiasticus*” is an apocryphal book, generally attributed to “Jesus, the son of Sirach.” The first fifteen verses of the thirty-eighth chapter relate to sickness; and though it has no claims to inspiration, yet (from its undoubted antiquity) it is very curious; on account of the notices which it gives of “the physician” and the “apothecary.” Express mention is made of “medicines,” and infusions of wood are plainly pointed out. We subjoin the passage:—

*Imperfect Mastication.*—Nature does not intend lumps of food to go into the stomach. On the contrary, she intends it to be prepared,—to pass through a certain process before it enters the great organ of digestion; and therefore imperfect mastication will produce dyspepsia, without any fault in the part itself. Old people, when they lose their teeth, or young ones when they cannot chew as before, and cannot live on spoon victuals, are very subject to indigestion. But, independently of a particular *quality* of food, or a great *quantity*,—variety, or a great discordancy of meats, will occasionally produce dyspepsia.

*Sympathy.*—Still speaking of causes unconnected with a fault in the stomach and intestines, we may mention “sympathy.” These parts are frequently deranged through the state of other organs. In the first place, we may refer to the uterus. When the uterus is pregnant, the alimentary canal is often thrown into disorder. Nausea, vomiting, and strange longings of appetite, will sometimes occur in females, the very next morning after they are impregnated; and sometimes these will occur at the time they quicken. There is every degree of intensity of these affections. They occur continually in diseases of the kidney; and frequently in mesenteric disease. The passions of the mind have great effect. If a person have eaten a good dinner, and has a violent emotion of mind,—whether joy or grief, or any other,—he will most probably have a fit of indigestion. Continued depressing passions have the same effect. Many cases of indigestion that I have seen, have been referable to an uneven state of mind. They have not depended on the stomach; but some external circumstance has weighed down the spirits; and the stomach has suffered in consequence of it.

The cause, however, may reside in the alimentary canal itself. In the first place, there may be a real debility of the part; in the next place, there may be an inflammatory state; and, thirdly, there may be organic disease.

*Debility.*—As to *debility*, that is sometimes induced by long continued excess in diet and regimen. Persons who have indulged excessively, all their lives, in eating and drinking, may expect to be subject to dyspepsia,—to have their stomach worn out; but this state frequently arises from original debility of the stomach. There can be doubt that the stomach may be in fault;—like all other parts of the body. This affection will run in families, where there has been no excess whatever. We may see the father or the mother and the children labouring under this disease in various degrees;—none having committed any fault calculated to produce it. Certain portions of the stomach may be feeble; or the muscular fibres may become weak;—like muscles in other parts of the body. Some persons will have *one* muscle weak, and some *another*.

*Inflammation.*—There may, however, be an *inflammatory* state; and this may be either primary or secondary. It may be induced like any other inflammation; but, in most instances, it is chronic; and is induced by constant irritation of the stomach. Sometimes it is a mere secondary effect. The stomach has been affected with weakness; till it has fallen into a state of morbid irritability, and ultimately into a state of inflammation.

*Organic Disease.*—Sometimes, however, we have what is far worse;—*organic*

“Honour the physician with the honour due unto him; for the uses which you may have of him; for the Lord hath created him. For of the Most High cometh healing; and he shall receive honour of the king. The skill of the physician shall lift up his head; and in the sight of great men he shall be in great admiration. The Lord hath created medicines out of the earth; and he that is wise will not abhor them. Was not the water made sweet with wood; that the virtue thereof might be known? And he hath given men skill; that he might be honoured in his marvellous works. With such doth he heal men; and taketh away their pains. Of such doth the apothecary make a confection; and of his works there is no end; and from him is a sweet odour diffused around. My son, in thy sickness be not negligent; but pray unto the Lord, and he will make thee whole. Give a sweet savour; and a memorial of fine flour; and make a fat offering. Then give place to the physician; for the Lord hath created him. Let him not go from thee; for thou hast need of him. There is a time when, in their hands, there is great success. For they shall also pray unto the Lord;—that He would prosper that which they give for ease and remedy,—to prolong life. He that sinneth before his Maker, let him fall into the hands of the physician.”

disease of the stomach; and then the indigestion, and all the other symptoms which I mentioned,<sup>a</sup> are irremediable. Generally it is the cardia or the pylorus which is affected; but sometimes (as I before stated<sup>b</sup>) there may be an ulcer in the body of the stomach; and this ulcer may be either simple or scirrhous. Sometimes there is no ulcer; but the coats of the stomach become thickened or softened. All those circumstances that I spoke of, when treating of organic diseases of the stomach,<sup>c</sup> may occur. I mentioned, that the softening of the stomach has sometimes come on suddenly;—has appeared not to have existed above a few weeks, and sometimes not more than a day or two.<sup>d</sup> I also mentioned that this softening was sometimes decidedly inflammatory;<sup>e</sup> and that sometimes there was no mark of inflammation at all;—the parts being perfectly white.<sup>f</sup>

*Prognosis.*—From a consideration of all the causes producing disorder of the digestive organs, we see that occasionally it is quite independent of the stomach and alimentary canal; and we have only to remove the unfavourable external circumstance, and all goes on right again. Sometimes the causes are of a nature independent of external circumstances, and are removable; or, if not removable, are in some measure controllable. In other instances, it is impossible to cure the affection, or even to control it much. The prognosis, therefore, must also depend upon what we ascertain to be the cause of the disturbance.

### SECTION III.—TREATMENT.

*Removal of urgent Symptoms.*—The first thing to be done, is to alleviate urgent symptoms. Suppose that any thing injurious in its quality or in its quantity is the cause. The shortest way then will be to give an emetic, and empty the stomach; and it is much the best to give one that does not produce nausea, but an evacuation. The sulphate of zinc is as safe as any thing that can be exhibited. The flour of mustard has also been exhibited, for the same purpose. But should the patient be of an exceedingly full habit,—for instance, a fat, short-necked, puffy, asthmatic alderman, fifty or sixty years of age,—it may be necessary to take away blood, before giving an emetic; otherwise the exhibition of the latter may cause apoplexy. In some cases, it might be proper to premise bleeding; but in every case it is right to follow up the emetic by purging. Nothing is better than eight or ten grains of calomel, followed up by senna and salts. We thus empty the patient above and below; and he is soon relieved.

If the symptom be gastrodynia, and we cannot find any thing in the stomach that has occasioned it, then tincture of opium is an excellent remedy. In the continued form of the disease, prussic acid will answer better; but I never saw it succeed when it was given for immediate effect. When we wish that, I think a full dose of opium is best; and laudanum will act rather more quickly than solid opium. Sometimes it is necessary to give a large dose in this state. Twenty drops have no effect; and we have to give forty, fifty, or sixty, and to repeat the dose every half or three-quarters of an hour; for it produces none of the specific effects of opium. Occasionally, it is better to give the opium in plain, hot water, than in a tincture or brandy; because, after a violent spasm, there is sometimes inflammation. Occasionally, I have seen people labour under inflammation, after spasm has been removed;—not because they took opium, but because they took a quantity of brandy. Sometimes we must repeat a dose of laudanum, containing forty or sixty drops, two or three times, before the good effect is produced.

If the patient labouring under this disease, however, is of full habit, it is useful to bleed. Sometimes I have seen gastrodynia cease when the bleeding was over. Venesection is often among the best antispasmodics. After a spasm, tenderness may come on; and then bleeding at the arm, or the application of leeches, may be

<sup>a</sup> See Pages 944 to 949.

<sup>c</sup> See Pages 910 to 912.

<sup>e</sup> See Page 902.

<sup>b</sup> See Page 908.

<sup>d</sup> See Pages 899 and 902.

<sup>f</sup> See Page 901.

necessary. But the affection frequently occurs without any marks of an inflammatory state; and then laudanum is sufficient to remove it. Hot external applications are exceedingly useful. The temperature falls in this state; and it is exceedingly pleasant to the patient to have a hot fomentation, or hot substances of various kinds applied,—not merely upon the stomach, but also to the back. I need not say that a hot-bath, if it can be procured, would be useful. This state is often called “the passage of a gall-stone;”—for no reason whatever, but that it comes on suddenly. We are never justified in saying, that an individual is passing gall-stones, unless he has passed them before, and they have been really found; because a pain of this description may come on in a moment, from eating an article which does not suit that particular individual; or an external circumstance may occasion it; and there is no difference, as regards pain, between it and the passage of a gall-stone.

If the urgent symptoms that require to be removed are heartburn, acidity, and a scalding sensation in the stomach, rising to the throat, magnesia, the carbonate of soda, and things of that description are the best. They will remedy this state chemically in a moment, without reference to the disease itself. In the healthy stomach, there is muriatic acid. As soon as food is taken, muriatic acid is formed; and, in some persons, it is generated in such great abundance, that it produces this affection. If there be very fetid eructations, from something putrefying in the stomach, and if the latter be overloaded, distended with them, it is best to give an emetic. If there be no reason for giving an emetic, two or three drachms of the common solution of the chlorurets might be given; and common acids, also, will answer very well. These, however, are means to be resorted to only when there are symptoms particularly urgent that require removal. We have more to do in order to cure the disease; and we must lay down for the patient a system, for the regulation of his habits and employments.

*Cure of the Disease.*—Having spoken of what ought to be done, in the way of lessening any very urgent symptoms that may arise in disorders of the digestive organs,—particularly in a violent attack of gastrodynia,—we will now consider what is to be done for the cure of the disease;—what is to be done in the way of a regular plan for the termination, or alleviation, of the complaint. In the first place, we must ascertain the cause of the disease; and if it be external to the stomach, we must proceed accordingly.

*During Pregnancy.*—In females, this disorder very frequently arises from the state of the uterus. In pregnancy, it is very common for the stomach to fall into such a state of disorder, that the patient's life, for a time, is rendered miserable; and occasionally, from the constant vomiting,—from the inability to retain any food whatever on the stomach, life has really been brought into danger. In very extreme cases, it has been judged right even to induce premature labour, for the purpose of putting a stop to this great disorder. In ordinary cases, however, although we cannot cure the nausea and vomiting, much may generally be done to alleviate them;—not by removing the pregnancy of the womb, but by lessening the irritability of the stomach, so as to make it sympathize with the uterus as little as possible. Simple bleeding at the arm, has frequently been sufficient for this purpose; and so has the frequent application of leeches to the epigastrium. All those medicines which I shall hereafter mention, (when speaking of another head of treatment,) as calculated to lessen the morbid irritability of the stomach, will here be proper;—such as strychnine, conium, and prussic acid.<sup>a</sup> It is also proper that the patient should take but a small quantity of food at a time. But I will speak more particularly of this presently.<sup>b</sup>

If we can ascertain that the disease (as is not uncommon) proceeds from a hernia, the application of the taxis may be the only means of curing the dyspepsia. If we discover that there are worms, the remedies necessary to destroy them will be proper. These remedies I will consider hereafter.

<sup>a</sup> See Pages 957 and 958.

<sup>b</sup> See Page 955.

*Sluggishness of the Intestines.*—Very frequently, the stomach is not in fault; but there is a sluggishness of the intestines; and, as the cause is situated there, a regular course of purgative medicine will be found absolutely necessary. It is wrong to give *strong* purgatives. Those which open the bowels regularly, are best adopted for the purpose. It is astonishing how long things taken into the stomach and intestines, will remain quiet; and then give rise to various symptoms. I alluded to the circumstance before.<sup>a</sup> In the "Philadelphia Journal," for 1822, there is an account of a coagulum of milk, which was vomited two months after it had been taken. I have myself seen a coagulum of milk, like bird-lime; which had remained some days (even a week) in the patient's stomach, and produced the greatest uneasiness;—the stomach not being in fault, but being oppressed by this particular substance. I have seen a piece of salmon vomited by an infant, a month after the nurse had been so foolish as to give the child that food. I mentioned, that Dr. Barlow (of Bath) published a case, in which pills of sulphate of iron were discharged, *per anum*, nine months after they had been taken.<sup>a</sup> In a foreign journal, a case is mentioned, similar to that of Dr. Barlow's;—a case in which pills were vomited, a year after they were taken. An instance is recorded, in which a blacksmith's son bolted thirty grapes. He did not *masticate*, but swallowed them *whole*; and, after three months frequent vomiting and extreme suffering, he was cured by an active purgative medicine. Ten of the grapes came away whole, even then. A case is mentioned by Bartholini, where a coagulum of milk, as large as a man's tongue, was discharged, after the patient had taken muriatic acid. The same author also mentions a case, where a patient had swallowed a swine's tooth. He suffered under hypochondriasis and extreme emaciation, for two years; the tooth was then discharged *per anum*; and the individual perfectly recovered. Occasionally, then, we may have disorder of the digestive organs from articles which have been taken, and have remained in the stomach and intestines a much longer time than we could imagine. If, in a case of disorder of the digestive organs, we suspect any thing of this kind, we ought to employ strong remedies. Purgatives and injections, of course, are very important.

But whether this be the cause of the disease or not, it is of the highest importance to keep the bowels regular. Nothing can be worse than to give strong purgatives for this purpose; except where there is something considerable to be brought away. In a case of habitual costiveness, strong purgatives are decidedly bad; because, when we have once acted violently on the intestines, the latter, according to the laws of nature, must fall into a torpid state,—go to sleep. During this condition of repose, the feces accumulate again; so that we have to give another strong dose, in order to remedy the mischief of the first. Thus the person is always constive, or taking strong medicines; the consequence of which is, that he is at last obliged to take them, or he will fall into a state of dyspepsia.

*Croton Oil.*—One of the best remedies for this state, is a very minute quantity of croton oil, (about the twelfth, the sixth, the fourth, or the third of a drop) given regularly with rhubarb or colocynth; and if it should gripe, a small quantity of some aromatic oil may be added to it. We may order one, two, or three drops to be made up into pills; and make the patient take one every night. We shall soon find that it will produce one copious stool in the morning; and also that the medicine may be taken for two or three years, perhaps for ever, without losing its effect. The patient will not be under the necessity of increasing the dose. If, however, we give it violently, the patient will be in the same condition as if he had taken other purgatives;—he will be constive afterwards.

*Inpropriety of Blue Pill.*—Nothing can be more absurd than to give blue pill, calomel, and other mercurial medicines; because they have a two-fold operation. They not merely act as cathartics, but they also pervade the whole system; and thus make the patient weak and nervous. These medicines do more than we want. We merely require the intestines to be acted upon; and not the intestines at large

<sup>a</sup> See Page 933.

to be put under the specific action of mercury. If Mr. Abernethy had lived a hundred years, and done good all the time, he would not have atoned for the mischief he has done, by making people take blue pill. Half the people in England have been led to fancy, that they cannot live without blue pill; which not only does no more good than any other purgative, but likewise renders those who take it constantly susceptible to cold; and must altogether be very injurious.

*Excessive Torpidity of the Bowels in some Persons.*—I may here mention, that there are some persons who have naturally very torpid bowels;—to whom it is not natural to have a motion every day. I presume that, in ninety-nine cases out of a hundred, it is natural for the bowels to be emptied once in the twenty-four hours; but there are some who do not have a motion oftener than once in three or four days; and they are ill if they do. I have met with such cases. Dr. Heberden knew a person who, all his life, had but one motion a month.<sup>a</sup> As a contrast to this, Dr. Heberden mentions another individual, who had twelve motions a day, for thirty years.<sup>a</sup> That must have been a very troublesome state of things;—a kind of “perpetual motion.” This same individual had, after this period, a motion seven times a day, for seven years. Women are much more costive, and suffer this with more impunity, than men; on account of the pelvis being large, and the rectum distending. Nothing is more common than for women to say, that they have been a week, or ten days, without a motion. We must therefore take into account, that it may be natural for some individuals to have a motion only every few days.

*Watch the state of other parts of the Body.*—In a case of disorder of the digestive organs, we should always examine into the state of other parts of the body; for this condition will take place, from sympathy, not only with the uterus, but with other organs. A very common cause of this disease, is disorder of the brain;—what is commonly called “disorder of the mind.” From anxiety, grief, and distress of mind, many persons have complaints of the stomach. So far as the stomach itself is concerned, they have no reason to find fault; but, from the state of the mind, the stomach cannot do its duty. Excessive anxiety, or grief, will not only take away the appetite, but will produce constant imperfection in the functions of the stomach; together with all those symptoms of indigestion, and derangement of the digestive organs, which I formerly mentioned.<sup>b</sup> I have very frequently been unable to do any material good, because the complaint evidently depended upon the state of the mind; and very frequently I have gained credit where I deserved none, simply from the circumstance of the unhappy state of mind ceasing. I have very frequently attended young ladies, who could not digest;—who had flatulence of the stomach; no appetite or great appetite; every thing wrong;—simply because there was an anxiety respecting love affairs. They were in fear of disappointment; and as soon as the affair was settled, they ate, drank, and digested like other people;—without any inconvenience; but, on the contrary, with great benefit. I have frequently been baffled in what appeared good rational treatment, because there was some grief of mind, or some constant anxiety.

*Snuff-taking before Dinner.*—It is always right to look out for any particular habit;—to see whether the patient is in the habit of doing any thing, to which the disease can be attributed. Dr. Cullen mentions two cases of dyspepsia, from patients taking snuff before dinner. In one of these two cases, the disorder of the stomach was gastrodynia,—aching pain of the stomach; and in the other case, there was a complete loss of appetite. Now both these individuals, on being particular not to take snuff before dinner,—taking as much as they chose when the stomach had something in it, recovered from their dyspepsia. The one lost his gastrodynia entirely; and the other recovered his appetite.

*Smoking.*—With regard to myself and tobacco, although I have a stomach that will digest any thing in the shape of proper, good, nourishing food, yet if I smoke three cigars in a day, or smoke three or four successive days, it invariably produces

<sup>a</sup> “Medical Commentaries,” Chapter 5.

<sup>b</sup> See Pages 944 to 949.

the most extreme gastrodynia and cardialgia,—so as to make me quite miserable; and therefore I am compelled to be temperate in that respect.

*Protracted Abstinence.*—Many persons have this disease, from going too long without food. Habit has a great deal to do here. Some persons who breakfast at nine in the morning and dine at seven in the evening,—taking nothing in the mean time, feel no inconvenience; and others suffer the *greatest* inconvenience, if they fast more than four or five hours. Habit will not operate on some people, with regard to this point;—some persons cannot be brought to fast long; and it is vain for them to attempt it. They feel a sinking in the stomach;—they have gastrodynia induced, if they do not eat frequently. Some cannot pass above four hours without food; and in proportion to the labour undergone, is the necessity of eating. In making inquiry into dyspeptic cases, therefore, we should ascertain how frequently the patients eat, and also whether they eat too much; for the stomach must not be blamed, because it does not do double or treble the duty that nature intended. It is said that, in the reign of Henry the Sixth, the people ate but twice a day; “whereas,” says Hollinshed, “we have breakfast in the forenoon, beverages or nunchions after dinner, and thereto rear suppers when it is time to go to rest. Now these additional repasts, thanked be God, are very well left out; and each one contenteth himself with dinner and supper only.” Another point is to ascertain whether the patient masticates his food. Many persons gobble up their dinner, as a hog would do, instead of masticating it properly.

*Change of Diet.*—The patient's diet should be regulated. Some nations live on fish; others on putrid animal matter; and others on vegetables. An eagle has been brought to eat bread, and a pigeon to eat meat;—the former being a bird of prey, and the latter a *domestic* bird. John Hunter brought a hawk to live on bread. If these changes be accomplished slowly, they may be well borne; but many cases of indigestion arise from persons suddenly changing their diet. It is mentioned that our countrymen who were prisoners under Tippoo Saib, were fed during their confinement upon nothing but rice, water, and capscums; and on their return, when they were liberated, they of course ate as before. The suddenness of the change, even to their former diet of meat, produced violent diarrhœa. Very frequently persons suffer, in this respect, from a change of food; and even from a change of place;—from having different bread from that to which they have been accustomed, and different water from that which they formerly had. We see the effect of habit, every day; for the lower orders, without appearing to suffer from it, will eat such butchers' meat, and such fish, as would disorder the stomach of their superiors.

*Most appropriate Food.*—There can be no doubt that, generally speaking, food is best composed of a mixture of vegetable and animal substances. It appears from the teeth, and likewise from the experiments made with the solvent juice of the stomach, that digestion is most likely to take place with facility, and in perfection, if the diet consist of a portion of animal and vegetable substances. In general, too, the food is much better digested, if a certain degree of art be applied in its preparation,—the art of cookery. Some persons, with weak stomachs, require this art in full perfection. They do not digest things, unless they are thoroughly boiled,—thoroughly pervaded by heat,—either *dry* heat, or heat and *moisture*; and even then they require the addition of good spices. With regard to patients labouring under this affection, therefore, it is necessary to ascertain whether they have made any change in diet; whether the meat they eat is good of the kind; whether they eat a proper proportion of animal and vegetable food; and that they do not eat things raw, which might be dressed. Many person, for example, have indigestion only when they eat articles not thoroughly cooked; and some persons digest every thing, except raw vegetables, salad, and radishes.

*Superiority of some kinds of Meat.*—In general, brown and old flesh is better digested than young meat. Mutton is easier of digestion, for example, than veal; and capon than a young chicken. In general, meat that is not particularly fat, is better digested than when it is; and lean is better digested than fat itself. Fresh

meat, too, is usually better digested than salt meat. Salt hardens the fibre, makes it more compact, and less easy of solution. Dr. Robinson addicted himself to taking a vomit every evening; and he found that he brought up veal undigested; but when he dined on beef, very little remained;—showing that the latter is of more easy digestion than the former;—*old* flesh than *young*. With regard to *fat*, it is a curious circumstance that some persons who can digest but few things well, can digest a piece of broiled bacon thoroughly; and it is now the fashion to take broiled bacon, as a thing very easy of digestion. Mr. Cunningham, a surgeon, who wrote an account of New South Wales, states that he knew a person, in whom the smallest portion of the fat of beef or mutton deranged the stomach; and she was forced, before she could take gravy, to allow it to get cold, and then have it skimmed, and warmed again;—so that not a particle of fat remained in it. Yet she could eat broiled fat bacon with impunity.

*Regulate the Quantity of Fluid.*—Another point to be attended to is, not to take much liquid food into the stomach;—not to indulge in broths and slops; which are so much animal matter, with water into the bargain. It is better to take animal food in a compact form, than in a quantity of hot water; because, no doubt, this quantity of liquid is injurious to the stomach. It dilutes the gastric juice; and (we must suppose) relaxes the stomach. It must both sodden it, and diminish its powers. Were there no other reason than that which I have just assigned, it would be wrong to drink too much liquid of any sort,—even beer, and tea. One of the best things to drink after dinner, is a cup of very strong coffee, without any milk. Some persons, however, are so stimulated by this, that they cannot bear it. But, in general, it is a good rule for dyspeptic people to limit their quantity of drink as much as possible; to take no slops or broth; and, in preference to drinking beer or water, to take a cup of strong coffee. With regard to vegetables, waxy potatoes are seldom well digested; and it is necessary that greens should be thoroughly boiled;—that is to say, boiled vigorously in a large quantity of water.

*Best kinds of Wine.*—Many persons are much better without beer or wine; but some have a stomach so languid, that it requires the stimulus of wine. We cannot prescribe any particular wine. For some persons, Port is best; for others, Sherry; and for others, again, Madeira. With some people, Port turns acid, and with others Sherry; but, in a great number of cases, Sherry agrees best with the stomach. A mixture of wine is bad; and persons will frequently bear Port, Sherry, or Madeira alone, when they would be made ill by taking any two of them together. But some add beer to a mixture of wines; and then we may expect a treble commotion in the stomach. Some say, that if they take a glass of brandy, it settles all;—it is like oil poured on the sea in a swell. But we find that many persons have stomachs so susceptible, that no wine can be drunk; and, indeed, nothing but brandy and water can be borne. Burgundy, Champagne, home-made and all sweet wines, generally disagree with the stomach. Still we meet with exceptions; and we may find cases where vomiting is stopped by Champagne. All Rhenish wines are sour, and likewise claret; and these usually ferment in the stomach, and become acid; and therefore they are improper. Generally one wine only should be taken; and that which usually answers best is Sherry.

*Impropriety of Suppers.*—It is well to prevent persons labouring under this complaint from eating suppers; unless they have had an early dinner. If people dine at one or two o'clock, it is necessary for them to take something in the evening. Now and then, we may meet with persons who are not so well without a good supper. They will lie awake from irritability brought on by exhaustion, unless they eat suppers; and therefore there is no rule for these things. There are general rules,—such as I have now mentioned; but we must never stand up for them universally. We must make exceptions; and adopt what we find the patient's constitution requires.

*Brown Bread.*—It is very proper to advise some persons to eat brown bread, instead of white. Many persons will not be costive, if they eat brown bread; but, in others, it produces a degree of heartburn, and acidity.

*Rest after Dinner.*—It is almost always right to advise persons to remain quiet after dinner; for if there be much moving about, digestion does not go on so well. It is a common saying—

“After dinner sit awhile!”

and it is also said—

“After supper ride a mile!”

This is not to digest the supper; but because the person should eat so light a supper, that he may ride a mile afterwards, without doing himself any injury.

We thus perceive that much may be done, in the way of curing disease of the digestive organs, without any medicine at all;—simply by discovering the cause, and removing it; and this cause is very frequently some bad habit. It is absurd in every case of affection of the stomach, immediately to order something. We should sit down, and learn the history of the case;—ascertain if the cause is beyond the stomach; if it has its seat in any other organ; what is the state of the intestines; what is the condition of the mind; whether the patient has been fasting too long, or eating too much, or taking something that disagrees with him. If it arise from any of these causes, we may cure the disease without any medicine;—may put the patient in possession of a plan, which will put a stop to his ailments. I am quite sure that, in the greater number of cases of indigestion, the disturbance arises from things forced into the stomach, from the state of the mind, or from some injurious habit which the patient has contracted; but it is necessary to attend to all the points I have mentioned, with regard to diet; for some persons have such weak stomachs that they require a particular line of conduct. Articles which produce indigestion in some people, will not give rise to it in others.

*Is there Inflammation?*—We may perhaps, however, have to treat disease of the stomach itself. Independently of all external circumstances,—of things external to the stomach, the stomach itself may be in fault. Having cleared the way so far, we should look out for gastritis. If we find a great sensation of heat in the stomach, and up the throat, and if we find the part tender on pressure, the case must be treated like any other inflammation. Leeches frequently applied to the pit of the stomach, moderate purging, and mild diet, are the suitable means.

*Prussic Acid.*—If we find no such marks of inflammation;—if the stomach suffers pain when food is taken, although there is no pain on pressure; or if the stomach vomits,—discharges its contents, and yet there is no pain or heat;—we may conclude that the case is one of morbid irritability; and, for the purpose of lessening this, prussic acid is one of the best remedies. In gastrodynia, it answers exceedingly well. If there be inflammation united with this spasmodic pain, we must remedy that by leeches; but if there be merely spasmodic pain, or a constant aching at the stomach, prussic acid often answers very well. It is best to begin with one minim three times a day; taking care not to give it on an empty stomach; for a dose that will be borne very well when the stomach is *full*, cannot be borne when it is *empty*. All agents affect the stomach most when it is empty;—when they come in contact with it;—when they are not mixed with its contents, and consequently not diluted, and only applied partially to the organ. If we give some doses before meals, and others after it, it will not produce a uniformity of effect. It is best to equalize the dose, by giving it after meals. We may begin with a minim; and, in a day or two, increase it to two minims, then to three, and so on. The symptoms of an unpleasant kind which it produces, and which are sufficient to make us limit the dose, are sickness, faintness, convulsions, and a little pain in the head. We must tell the patient of these things, and guard him against their occurrence;—desiring him, if they take place, to diminish his dose of medicine immediately;—not to take so large a quantity again, but a smaller dose. Then, as to the dose, there is no rule whatever. I had a patient, who could not bear more than the fourteenth or seventeenth of a drop without uneasiness; and I had another who said he took seventeen minims, three times a day; but he could not get beyond that. I have several times seen patients, who took eight or nine minims three times

a day; and even that is a large quantity. The dose that is usually borne, varies from two to four minims.

*Stramonium*.—Hyoscyamus, conium, and strychnine, are given for the same purpose; but stramonium and opium, I think, are better than any of these. I think stramonium is the best; because opium confines the bowels; and that is injurious in these cases. I have seen stramonium cure this pain in the stomach (gastrodynia). There is no rule for the dose of this medicine; but it is well to begin with half a grain, two or three times a day; and gradually to increase it, while there are no unpleasant effects. These effects are pain of the head, convulsions, and giddiness; and if the remedy be given incautiously after these begin, we may have drowsiness, violent pain, violent throbbing of the temporal and carotid arteries, and sometimes thirst, and great dimness of sight. If the two latter symptoms are not considerable, the patient may bear them; but if convulsions, giddiness, and pain of the head be induced, it is well to omit the remedy immediately; and then to give a smaller quantity. With regard to the feeling of morbid irritability, that is much better put a stop to by prussic acid, than by stramonium. I have frequently seen it stopped by the first or second dose; but I think that the gastrodynia,—the aching of the stomach, is best relieved by stramonium. Prussic acid answers very well; but I have seen it fail, where stramonium cured the case with facility.

*Conium; Opium*.—Next to stramonium, conium answers very well; but very frequently it requires to be given in increased doses,—up to ten, fifteen, or twenty grains, three times a day. Opium is also proper in these cases, if the patient's bowels are relaxed, and we are anxious for the medicine to have a double effect.

*Bismuth*.—The trisnitrate of bismuth has been used to lessen gastrodynia; and, no doubt, with good effect. The Unguentum Antimonii Potassio-Tartratis has also been employed. It is well, in these cases, to give but a small quantity of food at a time; for the stomach, when much distended, falls at length into a spasmodic state. The more distended the stomach is, the greater effort does it make to contract, and the greater is the spasm; and therefore a small quantity of food is proper.

The symptoms of morbid irritability of the stomach may be united with gastrodynia, and we must remember that the morbid irritability may, at different times, amount to inflammation; so that the remedies which, in the first place, were calculated to relieve it, will no longer do so; and the remedies for inflammation must be employed. We are never certain, from day to day, whether the symptoms depend upon inflammation or morbid irritability. Occasionally we have to apply leeches, and the remedies proper for inflammation; at other times, those that I have now mentioned; and frequently we have to employ both; for there may be a degree of tenderness;—but more *pain* than *tenderness*;—so as to render both plans proper. Frequently prussic acid and conium are improper; the remedies for inflammation being required. In other cases, the remedies for inflammation are improper;—the patient requiring narcotics; and, again, there are other cases, where *both* plans are proper.

*Aromatics and Stimulants*.—We may have another condition of the stomach;—where there is no gastritis,—no inflammation,—no morbid irritability independent of inflammation; but where the stomach is *torpid*. Some persons have what is called “a *cold* stomach.” They can digest their food, if they take brandy and cayenne pepper. Now in indolence of the stomach, aromatics are generally good;—mustard and cayenne pepper; and with regard to medicines, ether, camphor, fetid substances, and ammonia, will be found useful. Dr. Baillie says that where, in disorder of the stomach, a quantity of viscid mucus is discharged, the compound tincture of benzoin is an excellent remedy; but where there is pain on pressure, I would not give such a stimulating medicine.

In disorders of the stomach, it would be absurd always to tell patients to abstain from wine, and to take nothing rich; for some persons digest better if they take a few spiced articles, and a few glasses of wine,—perhaps even a pint. Some must have wine, and even spirits. In some cases of this description, the application of galvanism to the epigastrium has been found very serviceable. In this weakness

and torpidity of the bowels, tonics, of various kinds, are useful;—especially iron; and particularly Ferri Ammonio-Chloridum, which is one of the most stimulating preparations of iron. Bitters are useful; and to these, people often add soda; which is a good stimulant. Acids, as well as tonics, have been found useful; and they are often the best remedy for acidity; for they destroy that state of the stomach which gives rise to it. Nothing can be worse, in these cases, than for people to vomit and purge themselves, as they frequently do. It must weaken the alimentary canal. It is right to enjoin plenty of fresh air. Patients ought to avoid confinement; to have exercise short of fatigue; and constant pleasurable occupation, without care.

## CHAPTER X.

### WORMS.

It has been said that nature has provided every animal with other animals to prey upon it;—to make a habitation of it, and derive food from it. It is even said that a flea has its flea; and if so, I suppose, the latter would have its flea's flea. How far this matter goes, it is impossible for me to say.

*Divisions.*—Some of these animals evidently come from without, and perhaps exist but temporarily; and these are called “*ectozoa*,”<sup>a</sup> whereas those that colonize, establish themselves, breed a posterity, and become whole families at last, are termed “*entoza*.”<sup>b</sup>

### SECTION I.—ECTOZOA.

As instances of *ectoza* (those which reside upon the skin) I may mention fleas, lice, bugs, and other delicate little animals. But we have also others which reside *within*; some getting into the anus, some into the maxillary sinuses, some into the stomach and intestines, some into the biliary ducts, and some into the cellular membrane beneath the skin. I had a patient (an infant) who discharged about a dozen larvæ (maggots) of the common fly, all alive. The child had suffered from a chronic cough; but as soon as these dozen larvæ were discharged from the intestines, it lost its cough. I saw them myself in the napkin,—moving about in the fæces;—exactly as if they had never been in the body. I understood that it had eaten part of a high pheasant, some months before. I have had two cases, in which a live caterpillar was discharged from the intestines. One of these cases occurred in a woman who was in the habit of eating cabbage-stalks, when she washed them for dinner. The moth lays its eggs on cabbage-stalks; and no doubt this patient has swallowed some of the eggs; and it so happened that one of them was hatched.

Dr. Good, in his work on Medicine, gives an account of a flesh-fly (the “*musca cibaria*”), or rather the larva of it, being discharged by means of purgatives, after producing considerable derangement. The larva of the bee, and even live spiders, have been discharged downwards, from the alimentary canal, by human beings. Even the “*triton palustris*” and the “*lacerta aquatica*” (the *domestic* and the *horse-leech*) have been discharged by vomiting, and have been found in the stomach. Leeches, when they get into the stomach, will sometimes (from sucking the blood) attain so large a size as scarcely to be recognized. When soldiers have been encamped on marshy ground, it has been found dangerous for them to go to

<sup>a</sup> From *ἐκτα*, *animals*; and *εἰτος*, *without*, or *outside*:

<sup>b</sup> From *ἐκτα*, *animals*; and *εντος*, *within*.

sleep; lest leeches should get into their mouths and destroy them. Life has been lost from leeches crawling down the œsophagus into the stomach, sucking blood there, and producing fatal hæmorrhage. I once saw two centipedes, said to have been vomited by a girl twelve years of age. There was no reason to suppose that any deception was practised. She vomited them; and the vomiting was attended by a tightness in the throat. The animals had lived three days when I saw them. The mother said that, two months previously, the girl had vomited a black beetle. She had palpitation of the heart, pain, and heaviness of the head.

Dr. Duncan, in the ninth volume of his "Medical Commentaries,"<sup>a</sup> mentions the case of a boy, who discharged four caterpillars after a dose of calomel. It is said that several crawled out at the anus afterwards; and, on exhibiting calomel and jalap, an incredible number came away. He likewise discharged a lumbricus. It was ascertained, that he had frequently gone into the garden, and eaten a young cabbage-leaf;—just as I ascertained that the woman ate the stalks of cabbage, when preparing the latter for dinner.<sup>b</sup> I should not have paid much attention to these accounts, if I had not myself witnessed similar effects. I have no doubt that some persons are the sport of these insects; while in other persons they would die. In "Hufeland's Journal," for 1822, there is an instance of live and dead slugs being discharged by vomiting and purging. In the "Medical Gazette," Dr. Alderson (of Hull) states that a centipede was discharged from the stomach;<sup>c</sup>—exactly as occurred in the case that I saw.<sup>d</sup>

Horses have what are called "bots" in the stomach, if they swallow the eggs of the common gad-fly. The gad-fly, at a certain period of the year, lays its eggs upon their coat; they lick their coat, and swallow the eggs, which attach themselves to the splenic portion of the stomach. I suppose all this is natural; for I believe they are often found in the stomach of horses. Nature appears to have destined this place for their reception. When they are mature, they escape through the intestines, and become gad-flies.

Numerous instances of severe headaches have arisen from insects getting into the nostrils, and crawling into the frontal sinuses; and also from their getting into the "meatus auditorius." Nothing is more tormenting, I understand, than "a flea in the ear." If it get into the ear, it buzzes about, and makes as much disturbance as a giant would; but this state may be cured in a moment. I recollect the case of a patient of my own, who had been in the greatest agony from this circumstance; but on pouring a teaspoonful of oil into the ear, the flea was quiet in a moment. I suppose it was suffocated. There is a kind of gad-fly which settles in the rectum; and it is therefore called "*æstrus hæmorrhoidalis*." It has been found to make its way even into the womb. There is one kind called "*æstrus ovis*;"—from its always selecting sheep. The guinea-worm comes from without, perforates the skin, lies for a considerable period in the cellular membrane under the skin, and is the source of very troublesome ulcers.

## SECTION II.—ENTOZOA.

*Their usual Situation.*—As to those animals which settle regularly in the human body, colonize, and descend from one generation of human beings to another, they are found both in cavities and in the substance of the body; and each of these "entozoa" has its particular habitation. The one called "lumbricus," always occupies the intestines or stomach; the one called "strongyle," particularly fixes on the uterine organs; the one called "fluke," is found in the liver; and the "filaria," or "guinea-worm," is found in the cellular membrane. There are three principal forms of these animals, found in the living body. Those of one set are *round*,—in cylinders or spindles; those of another set are *flattened*, like bobbin; and those

<sup>a</sup> Page 223.

<sup>b</sup> See Page 959.

<sup>c</sup> See the "London Medical Gazette;" Volume 5; Page 306. (No. 105; December 5, 1829.)

<sup>d</sup> See the Previous Paragraph.

of the third set are *globular* or *vesicular*. It is the latter that are chiefly found in the substance of organs.

*Classification of Entozoa.*—Linnæus arranged them according to their *situation*;—accordingly as they were found in the intestines, or in other viscera. Rudolphi (the naturalist) of Berlin, names them from their form; and arranges them into five classes. The first of these he terms “*nematoidea*.”<sup>a</sup> He has a second class, which he calls “*acanthocephala*.”<sup>b</sup> These are animals of the hydatid kind. They have no spinal canal; have distinct genital organs; are of two sexes; and are found only, or chiefly, in the intestines of swine. Then he has a *third* class; which is called “*trematoda*.”<sup>c</sup> These are flat, with minute pores. It is said that these have no intestinal canal; but distinct genital organs. The *fourth* is “*cestoidea*,”<sup>d</sup> which include the different kinds of the “*tænia*,” or “flat worm;” and the *fifth* he calls “*cystica*.”<sup>e</sup> These are “*hydatids*.”

Cuvier makes more simple classes than these. He arranges, in separate classes, those which have a distinct digestive cavity, and those which have *no* distinct digestive cavity to be traced in the interior. Those of the first are called “*cavitaires*,” because they have a digestive cavity;—regular canals and an anus; and those of the other are called “*parenchymateux*,” because they have nothing but a uniform structure, with no regular digestive tubes. This last class embraces all the classes of Rudolphi except the first; and those which have a regular digestive apparatus comprehend the round worm, the little ascarides, the strongyle, and the guinea-worm; and therefore, instead of the *five* kinds of Rudolphi, Cuvier makes but *four*.

*Ascaris Lumbricoides.*—I will begin with the “*cavitaires*,” or, according to Rudolphi, the “*nematoidea*.” The first of these was formerly termed “*lumbricus*,” but it is now termed “*ascaris lumbricoides*.” This worm has external integuments. It has also muscles, a *digestive* apparatus, and a *genital* apparatus; and some have thought that it has a circulating and a nervous system. The muscles of this worm lie immediately under the skin. The fibres are two-fold;—both long and transverse. The digestive organs are quite straight. It has a triangular mouth, with three tubercles; the anus is at the opposite end; and the genitals fill a great part of the animal. Each sex is a different individual; and the opening of the genitals is near the anus. It is from twelve to fifteen inches in length; is of a yellow colour; and as many as eighty of them have been discharged from one individual. The celebrated professor Frank mentions a case, in which the intestines were absolutely crammed with them.

*Situation.*—This worm is usually found in the small intestines. Occasionally it is found in the *large* ones, in the stomach, the œsophagus, the pharynx, and the mouth;—for I have known a person vomit one; but its proper habitation appears to be the small intestines. Andral says that he found a lumbricus in the pharynx. It got out of the small intestines into the stomach; from the stomach into the pharynx; and then one end turned down into the larynx, and there caused sudden death by suffocating the patient. Andral also saw several in the liver;—having apparently crept up the “*ductus communis choledochus*,” from the duodenum. Dr. Baron, of Gloucester, mentions having seen a lumbricus in the ductus of the liver; and an old physician, who wrote on Morbid Anatomy, mentions having seen several worms in that situation. Andral says that he saw a liver absolutely perforated with them; and sometimes they have perforated the intestines, and got into the peritonæum. They have sometimes been known to escape externally through the integuments; or into the urinary bladder, or into the vagina.

*It resembles the Earth-worm.*—This animal resembles the earth-worm; but the earth-worm is found to be less pointed; its mouth is only a small slit at the under part of a rounded head; and the anus is not *near* the extremity, but at the *very* extremity. The earth-worm is more fleshy, and more marked with rugæ; and it

<sup>a</sup> From νημα, *a thread*; and εἶδος, *form*.

<sup>b</sup> From ακανθα, *a prickle*; and κεφαλη, *the head*.

<sup>c</sup> From τρημα, *an aperture*; and εἶδος, *form*.

<sup>d</sup> From κερτος, *a girdle*; and εἶδος, *form*.

<sup>e</sup> From κυστις, *a bladder*; and εἶδος, *form*.

has one most distinguishing circumstance,—a quadrangular row of processes, like feet; which it can erect and move about. It has also three longitudinal lines at the upper surface; and it is an hermaphrodite. The “*ascaris lumbricoides*” is by far most common in children; and is rarer as people grow old.

*Trichocephalus*.—The next worm, in point of size, is that formerly called “trichuris;”<sup>a</sup> sometimes improperly termed “the *three-tailed* worm.” Unluckily our predecessors mistook the *head* for the *tail*, and it is now called “trichocephalus.”<sup>b</sup> It is a very small worm;—about one inch and a half, or two inches, in length. It is of a violet-colour; and the anterior end is much finer than the posterior;—it becomes a mere point for the mouth. The posterior end of the male is bent; and it has a straight alimentary canal, around which are placed the organs of generation. This worm is found lower down in the alimentary canal than the last; for it occurs chiefly in the cæcum. There are generally several of them. It is much more common in infants, than in others.

*Oxyuris*.—Another worm which has also an alimentary canal, is the “*ascaris*”;<sup>c</sup> or, properly speaking, the “*oxyuris*,”<sup>d</sup> or “drop-tail.” This passes, with the common people, under the name of “thread-worm.” It lives as low down as it possibly can in the rectum, and frequently makes its exit; and when it once gets out, it cannot get back, but shrinks up and perishes. It is far shorter than the others. The male is said to be about a line and a half in length; the female four lines. The organization is the same as in the other two kinds. It is not only usually found in the rectum; but it is generally surrounded by mucus. These worms will crawl out; and patients sometimes amuse themselves by seeing how many they can catch during the night;—in order that they may show their exploits to the doctor, in the morning. I have known them to crawl out of old persons; so that they have complained that they picked them off their thighs in bed.

*Parenchymateux*.—Worms of the other description (called “parenchymateux” by Cuvier<sup>e</sup>) have no digestive or other perceptible organs, except instruments of locomotion. They have various forms; some are *spheroidal*, some *flat*, and some *long*. They are the “*acanthocephala*,”—with two points; the “*trematoda*,”—with a perforation; and the “*cestoidea*,” including those of which I am now going to speak,—“*tæniæ*.” These are found in the substance of the body, and in various cavities. Lastly, there are those which are called “*hydatids*” (“*cystica*”), and which are very frequently found in the substance of the body, but occasionally in its cavities; and sometimes they have a particular cyst.

*Tænia*.—I will now proceed to that worm, which we meet with every day in the living subject; and which is called “*tæniæ*.”<sup>f</sup> This animal is never less than several feet in length; and sometimes many yards. One author mentions a worm of this kind which measured one hundred and fifty feet; and another foreign writer saw one three hundred feet long. Though I never saw one so long as that, yet I have frequently seen seven, eight, or ten yards, come away at once. It is fine in structure, and has a series of articulations,—each with natural pores. Dr. Baillie<sup>g</sup> says, that the last joint has no aperture. The anterior part of the worm is very fine; the head is square; and it has little retractile hooks. There is no regular organization within;—that is to say, there is nothing leading to a digestive tube. It is almost a mere amorphous mass; yet we may feel arborescent vessels about the joints; and a serpentine canal is sometimes seen at the edges. It moves in an undulatory manner.

*Varieties*.—There are two kinds seen;—the one called “*tænia solium*”;<sup>h</sup> and the other “*tænia lata*.”<sup>i</sup> That which is called “*tænia solium*” is, towards the head, about the third of a line broad; and has crotchets before and on each side of

<sup>a</sup> From *τριξ*, a hair; and *ουρα*, the tail.

<sup>c</sup> From *ασκεν*, to move about.

<sup>e</sup> See Page 961.

<sup>g</sup> In his “*Morbid Anatomy*,” Chapter 8; Section 12.

<sup>h</sup> From “*solus*,” alone; because it usually infests the body singly.

<sup>i</sup> From “*latus*,” broad.

<sup>b</sup> From *τριξ*, a hair; and *κεφαλη*, the head.

<sup>d</sup> From *οξυς*, sharp; and *ουρα*, tail.

<sup>f</sup> From *ταινια*, a fillet.

the articulations. On this account it is sometimes called "*armed tænia*." The other, which is called "*tænia lata*," is shorter and broader; and has no crotchets. The latter usually exists in cavities,—three or four in an individual; and from twelve to fifteen feet long.

*Most frequent in Adults.*—The "tape-worm" is far more frequent in adults, than in children, and in the dog than in the human subject; but it is said that in the dog, and in other brutes, it differs somewhat from that observed in the human subject. It is more common in some countries than in others. In Switzerland, the water is very bad; and the "*tænia solium*" is very common there. The "*tænia lata*" is not so common.

*Strongyle.*—One kind of worm is found in the bladder; and this is called the "*strongyle*." The late Dr. D. D. Davis, of University College, London, once showed me a phial containing a large number of them,—all creeping about in full animation,—which came from the bladder of a female. She had discharged a large quantity of them, for a considerable time. Mr. Lawrence has described a curious case of this kind, in the second volume of the "*Medico-Chirurgical Transactions*."<sup>a</sup> In that case, from eight hundred to one thousand of these worms were discharged from the bladder in about a year. They were very hard and firm: and some were an inch in length. These worms cause great irritation, a frequent desire to make water, and sometimes bloody urine. In the fifth volume of the "*Edinburgh Medical Essays*"<sup>b</sup> (which is a very excellent work), there is an instance of one an inch in length, and as broad as the smallest part of a needle. It was discharged, after having produced bloody urine for many years. What could be done in a case of this description, I do not know. Whether turpentine given by the mouth would answer, is doubtful. It would find its way to the urinary organs, because it impregnates the urine; but whether in sufficient quantity to destroy the worm, I do not know. Whether it would be right to inject the bladder, I cannot tell; but first I should try an injection of olive oil;—just as I should kill a flea in the ear. Whether these worms are formed in the bladder, or come from the kidneys, I do not know. The point is not yet determined.

*Causes.*—It is probable that a great number of those worms which I have now been speaking of as "*entozoa*," really came originally from *without*. Many persons, on going to particular places, have presendy become subject to worms;—just like other people in that particular neighbourhood. Persons who, by accident, have drunk bad water, have frequently had worms from that time. There can be no doubt that "*tæniæ*" may be continually traced to external sources; and with respect to "*ascarides*," a remarkable case is published<sup>c</sup> in the Second Volume of the "*Transactions of the King's and Queen's College of Physicians in Ireland*;"<sup>d</sup>—a case in which a whole family was infested with this worm; and every servant who came to the house, after a certain time, had it. Although medicines were taken, yet nothing liberated these persons from it; and at last *ascarides* (very similar, but a little browner) were discovered in a well, from which the people derived all their water. The family had resided there many years, but they now found it necessary to change their habitation; and, from that time, nearly all of them lost their worms. The race was kept up in one individual. Dr. Darwin mentions that the fens of Lincolnshire are famed for *tæniæ*. Sir John Pringle says, that lunbrici are very common in the remittent fevers of marshy countries; and that when they have been once introduced, it is impossible to say how long they may remain. They may continue for many years. It appears to be a fact, that they may be transmitted from generation to generation. A German writer (of authority) says, that he actually found worms in the intestines of a fœtus. This is not at all surprising; for the germs may be easily transmitted from the mother to the offspring. Lamarck, the French naturalist, has found the same thing. *Tæniæ* have been seen in a muddy spring; only they were rather smaller than those observed in human

<sup>a</sup> Page 382.

<sup>c</sup> By Dr. John Miller Barry.

<sup>b</sup> Page 289.

<sup>d</sup> Page 390.

beings. The lower animals are easily altered by particular circumstances; and therefore it is not surprising that ascarides should be of a different colour and size *in* the body, and *out* of it;—in wells and in the living subject. I recollect being told by a friend, who had travelled a great deal in Syria, that he drank some bad water, and was exceedingly ill for a week or so. He did not know what was the matter with him; when, all at once, after taking a good dose of calomel, he discharged little more than a heap of small maggots. What they were, he was not naturalist enough to inform me; but he got well; and his illness could be traced to this external circumstance. Tæniæ may come from without; and so, it would appear, may ascarides; as well as, in all probability, the “*ascaris lumbricoides*.”

*Debility favourable to their Presence.*—Generally speaking, these worms prevail more especially in proportion as the patient is weak. We know that persons who are exhausted from fever, will become the subjects of vermin. In extreme debility of the constitution, a patient may be cleaned several times a day; and be covered with a fresh crop of vermin. So it is, in general, within. The more weakness there is of the body, the more the entozoa thrive. Bad air, bad food, and the want of sun, will contribute to their appearance. When rabbits are kept in a bad place, they become subject to hydatids; as do also sheep in wet pastures.

*Spontaneous Cessation.*—There can be no doubt that children are much more disposed to ascarides and to lumbrici, than other persons are; and not only so, but, as age advances, the constitution frequently becomes so unfit for the continuance of these worms, that they are absolutely shaken off without any medicine. I feel no doubt that children cease to become the prey of worms. Thousands have ascarides when they are young, and never have them afterwards. This is not so common an occurrence with regard to lumbrici, as with regard to ascarides; but the remark is correct there, to a certain extent. The early period of life seems to favour these animals;—why, I do not know. Some of these worms occur in persons of the highest health. Persons with a good colour complain of worms; and they will be able to verify their assertion.

*Symptoms.*—Worms sometimes produce the most distressing effects;—so as to make life a burden. At other times, they produce no symptoms at all; and a person only knows that he has worms, because he discharges them. I have seen many individuals who, to their great astonishment, discharged several feet of tape-worm;—not having had the least idea, previously, that there was any thing the matter with them.

In enumerating the symptoms, I will begin with the head, and go downwards;—for the sake of assisting the memory. When worms exist in the alimentary canal, the symptoms usually are headache, heaviness, giddiness, depression of spirits, and even convulsions. Sometimes the headache is sharp; sometimes it is dull; and frequently there is a stabbing of the temples. Perhaps there is regular epilepsy; and some authors even mention tetanus. There is a black circle around the eyes; paleness of the face; more or less tumidness of the upper lip; great itching of the nose; foulness of the tongue; thirst; offensiveness of the breath; palpitation; dyspnœa; cough; and even hæmoptysis. Then (to go below the diaphragm) we have either anorexia, or excessive appetite; nausea; vomiting; a gnawing pain at the “*serobiculus cordis*,” pain, perhaps all over the abdomen, or in various parts of it; griping; purging; itching of the fundament and genitals; a discharge of mucus from the rectum; feverishness; and emaciation. The pain of the abdomen is sometimes a *pricking* pain; and there may be tenderness of it. Of course, we do not see all these symptoms in every case; and sometimes worms will exist in the alimentary canal, without giving rise to any symptoms whatever.

*Treatment.*—As to getting rid of worms, in the first place, any brisk purgative may answer the purpose. A good dose of calomel and jalap is an old remedy, and a very excellent one. Sir John Pringle used to give twelve grains of calomel, and half a drachm of rhubarb. Some give gamboge; but I do not know its specific power. It produces nausea; and is not so good as calomel and jalap.

*Oil of Turpentine.*—But besides these remedies for the *expulsion* of worms, we

employ others for the purpose of *destruction*; and one of the best is, unquestionably, oil of turpentine. In the case of ascarides,—which are easily known from their crawling out, from their appearing in the stools, and from the extreme itching which they cause in the rectum,—it is best to give the oil of turpentine by injection. We thus send it immediately on the parts where the worms reside; save the patient the unpleasantness of a filthy dose; and save the stomach from great disturbance. From a drachm to half an ounce, mixed with gruel, may be given to a child; and it will often bring away thousands. Adults will take a larger dose in an injection;—an ounce or more; but perhaps a very large dose is not so well. It causes so much irritation, that it may produce an immediate expulsion. It may not lie long enough to kill the worms; but may be discharged from the intestines. In the case of other worms, the oil of turpentine should be given by the mouth; and the dose is then from half an ounce to three ounces. In females, half an ounce is generally a proper dose to begin with; and it is seldom right to give more than an ounce; but in men, if they be not particularly delicate, it may be right to give two ounces. It is best not to give it fasting, lest it should create sickness, and be lost. Patients had better take it a couple of hours after some meal; and they ought to remain perfectly quiet;—lest vomiting should be induced. It may be taken pure;—in the same way as a glass of spirits; or in gruel, or in any thing else which the patient chooses. The effect it generally produces, is that of making the patient sick, purging him violently, making him giddy, and causing extreme vertigo. These symptoms will all go off; but occasionally the medicine will not purge itself away; and therefore, it is best to give a dose of castor-oil; and to repeat it every hour or two, till the medicine passes freely. It rarely affects the urinary organs; but sometimes it does. Now and then we have bloody urine, a frequent desire to make water, and great pain; but, in general, these effects do not occur; and when they do, there is usually an idiosyncrasy; and they will occur from the smallest doses. Large doses usually work themselves off; but where they do not, I have seen these effects. Where the remedy does not produce irritation, it has been absorbed; and the urine has smelt strongly of it, for some days.

*History of the Use of Oil of Turpentine.*—The history of our knowledge of this medicine is rather curious. So far as I have read, it appears that its use, in the cure of worms, was first mentioned in 1792, by a general practitioner at Putney, named Malden.<sup>a</sup> A man had been long accustomed to pass tape-worm; and a friend advised him to take oil of turpentine. He took two drachms; and, to his great astonishment, discharged five yards of tape-worm, and several pieces afterwards. At the time Mr. Malden wrote, which was three years and a half afterwards, he was quite well. This fact was lost sight of,—not in the least attended to, till a paper was published, in 1811, in the “*Medico-Chirurgical Transactions*,”<sup>b</sup> by a physician at Durham.<sup>c</sup> It gives an account<sup>d</sup> of a sailor, who had been in the habit of taking gin to expel a tænia; but at last it failed; and he took a glass of oil of turpentine;—thinking that that was stronger. It was quite successful. What is very curious, after this paper was written, Dr. Walker, in 1817, published a paper in the “*Transactions of the London Medical Society*,”<sup>e</sup> in which Mr. Malden’s account was contained;<sup>a</sup> and claimed the discovery of the remedy. The circumstance was forgotten; and the Society allowed the second paper to be published. Oil of turpentine is one of the best remedies that we have. It will expel all sorts of worms;—ascarides, lumbrici, tæniæ, and all the others. Occasionally it will fail; but we should give it in large doses, and take care that it finds its way out. We should follow it up with a dose of castor-oil every two hours; otherwise the patient may be brought into some danger. I have seen a degree of danger produced in a child, from inflammation of the intestines coming on; but it went away in a

<sup>a</sup> See “*Memoirs of the Medical Society of London*,” Volume 4; Page 419.

<sup>b</sup> Volume 2; Page 21.

<sup>c</sup> Dr. John Ralph Fenwick.

<sup>d</sup> At Page 25.

<sup>e</sup> See Volume 1; Part 2; Page 114.

few hours. The oil of turpentine has been particularly used in the ease of tape-worm in the intestines; but it is equally good in the case of other kinds of worms.

*Dolichos Pruriens*.—The “*dolichos pruriens*” (“cowhage” or “cowitch”) has been used, particularly against the lumbrici; and the best account I can give of that remedy, is to be found in a work, written some years ago, by a general practitioner of the name of Chamberlain.<sup>a</sup> The pubes, or small spiculæ of the *dolichos*, are scraped off, and made into an electuary with treacle, or confection of senna; and the electuary may be given in almost any quantity. As good a mode of exhibiting it as can be adopted, is to thicken it to a proper consistency with treacle; and to let the patient take a tea-spoonful of it, two or three times a day. We should occasionally give a purgative. I have found the oil of turpentine so efficacious, that I have not had much recourse to “cow-itch.” A woman, at St. Thomas’s Hospital, took a drachm of the pubes of *dolichos*, twice a day, for five days; and afterwards a purgative was given to her. The only inconvenience which my patient experienced, was a tingling in the mouth; but when it had once got into the alimentary canal, no further unpleasant symptom arose.

*Pomegranate-Root Bark*.—The bark of pomegranate-root has also been particularly recommended. Half a drachm may be given every half hour, till vertigo is produced. A good account of this is given, in the eleventh volume of the “*Medico-Chirurgical Transactions*.”<sup>b</sup> It has the effect of producing giddiness, sickness, convulsions, pain in the head, and purging. There is no rule for the quantity that will produce these effects; and therefore it is well to give half a drachm of the powdered bark, in some water, every half hour, till the patient begins to feel sickness, or is purged. It is for the *tænia* that this is particularly recommended; and there can be no doubt of its virtue. These are the only things with which I am practically acquainted.

*Other Remedies*.—Steel-filings have been mentioned; and a woman once took an ounce and a half in a day. They purged off with a cathartic; but without any sensible effect whatever. A number of medicines are recommended in books on *Materia Medica*. The bark and shoots of the “bastard cabbage-tree,” and of the fern, have been particularly spoken of as a remedy for *tænia*. Indian pink (which is an acrid narcotic) has undoubtedly been useful. In the first volume of the “*Transactions of the College of Physicians in London*,”<sup>c</sup> is recorded<sup>d</sup> the case of a man who took two pounds of common salt, in four pints of water; and, by that means, got rid of an immense number of ascarides. It is well known that salt is rather a preservative against worms. The flukes which are found in sheep come, it would appear, from stagnant water; and it is said that, by given the sheep plenty of salt, we may prevent them from becoming the victims of fluke. Electricity has been employed,—the passing of shocks through the abdomen; and now and then a worm has come away. It has been rendered uneasy, and has endeavoured to escape.

*Restore the General Health*.—But besides those means which are necessary to expel the worms, it is of the highest importance to restore the health. There can be no doubt that worms derange the health; and if we can get rid of them, health will return. But they are frequently present on account of bad health; and therefore, though it is necessary to expel them by common purgatives (which often answer very well), we must, at the same time, endeavour (by all the means in our power) to restore the health; to take care that the patient has wholesome food, and to put the digestive organs into the best possible order. If this be done, worms will frequently disappear, without any other means being employed. Without giving any purgative medicines whatever,—without doing any thing to expel or destroy worms, in a great number of cases where children have become their prey,

<sup>a</sup> “Treatise on the Efficacy of Cowhage, in Diseases occasioned by Worms, &c. By William Chamberlain.”

<sup>b</sup> Page 301.

<sup>d</sup> By Dr. William Heberden.

<sup>c</sup> At Page 54.

they will spontaneously cease. Children are far more subject to ascarides and lumbrici than adults; and a great number of children have them at a particular time; but as puberty arrives, the constitution is less favourable as a habitation for worms; and they cease spontaneously. Most of us have been freed from worms spontaneously; although they may have been a great torment to us at the younger period of life.

*Entozoa originally Ectozoa?*—Before concluding the subject of these worms, I should state that we are not quite certain with regard to some of these, whether they deserve the name of “ectozoa” or “entozoa.” Those that *reside* and *breed* within (“entozoa”) have particular residences. Some invade the alimentary canal generally; and others reside in particular parts of the canal. The same thing has been observed with respect to those which reside on the surface. Whether they have an external origin or not, we are not quite certain. Then, again, there are some vermin (small lice) which live only in the head; and it is said that they will not thrive anywhere else. There are others which live only on the body; and it is said, that if we put them into the hair of the head, they die. These have been vulgarly named “crab-lice;” but scientifically they are called “pediculi pubis.” They thrive only on the pubes.

*Chigoes.*—There is a particular kind of flea,—very large,—a sort of giant,—which passes under the name of “chigoe.” This is found particularly among the negroes, and is a source of great trouble to them; for it is so powerful, that it gets under the skin, and there burrows, and forms a bag, in which it lays its eggs;—the result of which is a very troublesome ulcer. I had a patient at St. Thomas’s Hospital, who had lost the nail, and the extremity of each great toe, through chigoes. There was a cicatrix running across the toe; which cicatrix had been occasioned by this animal. The negroes are very expert at taking them out, in whomsoever they occur. The great point is to remove the bag entirely; for if any part remain, an oozing occurs, and no good is done. There is a story told of a person, who was anxious to have it put to the test, whether chigoes were a particular sort of flea, or only a variety of the common kind; and he therefore let one which had got under the skin, go on burrowing; in order that he might observe its increase and habits. The consequence was not only a troublesome ulcer, but mortification. A gentleman, who has been much in the West Indies, is of opinion that that kind of elephantiasis which is called “Barbadoes-Leg,”<sup>a</sup>—in which the skin becomes exceedingly hypertrophied,—and that disease of the scrotum in which the skin and the subjacent cellular membrane are excessively hypertrophied (just such a case as occurred in the Chinese at Guy’s Hospital<sup>b</sup>), all arise from chigoes. Whether he is right in his opinion, or what grounds he has for it, I will not pretend to say; but he is a man of very careful observation.<sup>c</sup>

<sup>a</sup> See Page 471.

<sup>b</sup> This refers to Hoo Loo, an unfortunate Chinese; who came over to this country, expressly to have a large tumour removed from the scrotum. The operation was performed at Guy’s Hospital; but the patient did not survive. An account of this case will be found in the “Lancet,” for April 16, 1831 (No. 398; Volume 2, 1830-1; Page 86). Mr. Liston has, in his Museum, an enormous tumour of this kind, which he removed successfully.

<sup>c</sup> The late Dr. Fletcher, of Edinburgh, with the view of assisting the memory, used to include in a table all the parasitic animals (twelve in number) to which the human body is liable. We give this table below. The nomenclature adopted is that of Rudolphi; but we have added a few synonyms.

I. Cystica (Hydatids).

1. Cysticercus Cellulosus (Bladder-tailed Hydatid).
2. Echinococcus Humanus (Acephalocyst).

II. Nematoidea (Cylindrical Worms).

3. Hamularia Subcompressa.
4. Ascaris Lumbricoides (Lumbricus).
5. Trichocephalus Dispar (Trichuris Vulgaris; Long Thread-Worm).
6. Oxyuris Vermicularis (Ascaris Vermicularis; Thread, or Maw-Worm).
7. Strongylus Gigas (Urinary Worm).
8. Filaria Medinensis (Dracunculus; Guinea-Worm, or Hair-Worm).

## III. Trematoda (Intermediate Worms).

9. *Dystoma Hepaticum* (*Fasciola Hepatica*; Flake).10. *Polystoma Pinguicola* (Fat-Worm).

## IV. Cestoidea (Tape-Worms).

11. *Bothriocephalus Latus* (*Tænia Osculis Superficialibus*; Broad Worm).12. *Tænia Solium* (*Tænia Osculis Marginalibus*; Long Worm).

Succinct remarks by Dr. Fletcher on the localities inhabited by these different animals, together with various other interesting particulars respecting them, will be found in the "London Medical and Surgical Journal," for June 17, 1837. (Page 318.)

# BOOK VI.

## DISEASES OF THE URINARY ORGANS.

---

### CHAPTER I.

#### DISEASES OF THE KIDNEY.

##### SECTION I.—NEPHRITIS.

ACCORDING to the rule which I have hitherto observed,<sup>a</sup> the first disease which I shall describe among those of the urinary organs, will be *inflammation*; and inflammation of the *kidney*; called “nephritis.”<sup>b</sup>

*Symptoms.*—In this disease there is pain in the loins; but it is usually experienced on one side only. On account of the great sympathy that exists between the kidney and the stomach, there is very frequently nausea and vomiting. In inflammation of the *heart* and *lungs*, there is no vomiting; but in inflammation of the *kidney*, we generally have more or less disturbance of the stomach;—either nausea, or absolute vomiting. From sympathy among different parts of the urinary system, there is usually a frequent desire to make water. The pain is not confined to the loins; but runs along the ureter, towards the bladder. The testicle of that side is generally painful and drawn up; and very frequently indeed it is swelled. There is also numbness in the inner part of the thigh;—I presume from an affection of the anterior crural nerve. The pain is seldom felt at the *back* of the *thigh*. It does not run down that part of the limb, like sciatica; but is felt *anteriorly*,—along the course of the ureter, down the testis, and down the inner part of the thigh; where the anterior crural nerve is situated. The testis, indeed, is sometimes not only swelled, but sore to the touch; and sometimes it, as well as the inner part of the thigh, experiences a sensation of numbness. The urine is generally scanty and red;—following the course that is usually observed in any active inflammatory disease; and, the kidney being the part affected, it is more scanty and of a deeper red in nephritis, than in other inflammations. On the other hand, the urine is sometimes not deficient in quantity; and occasionally it is found to be very pale.

*Diagnosis from Rheumatism.*—In a *rheumatic* affection of the loins, the pain is usually felt on both sides; and it is felt to a great extent;—it generally affects a large surface. It runs to the hip; and, if it extend at all, it proceeds down the outer part of the thigh;—taking the course of the sciatic nerve. There is not a frequent desire to make water; there is no pain in the course of the ureter, no enlargement of the testicle, nor any pain in the inside of the thigh. Motion, in that disease, very frequently produces pain;—perhaps extending to the thigh, and espe-

<sup>a</sup> See Page 69.

From νεφρις, the kidney; and “itis,” inflammation.

cially about the joint and the "trochanter major." The latter is not only painful, but perhaps hot and swollen. Very often there is rheumatism in other parts; and, very frequently, there is profuse sweating. The absence of all *urinary* symptoms (if I may so call them), and the situation of the pain,—in addition to the common symptoms of acute rheumatism,—enable us, in general, to distinguish the disease perfectly. I was able in one instance to make an accurate diagnosis, where some little difficulty was thrown around the case. In St. Thomas's Hospital there was a man, who had been there, six or eight months previously, for a decided affection of one kidney. There was pain in one part of the back, extending down the ureter; the testis was retracted; and there was an affection of the urine. The case was treated as *nephritis*. But he now came in with what was decided *rheumatism*. There was pain on the outer side, lower down than the kidney. It did not extend in the course of the ureter; but ran down the course of the sciatic nerve, and particularly affected the joint, which was painful on motion;—showing the effect of rheumatism. He did not make water more frequently than he ought; but there was pain in one point anteriorly. That, however, arose from an evident circumstance; it was in the situation of the glands, which were inflamed. He was treated by acupuncture, and making his mouth sore; and he speedily got rid of the disease.

*Causes.*—Nephritis may be produced by cold, like any other inflammation; but it is rarely an idiopathic disease. It is more frequently the result either of mechanical violence, or of some acrid matter which has been taken, such as turpentine or cantharides. Or it is the result of stones existing in the kidney, or of some disposition perhaps to gout.

*Termination.*—If the disease go on to great violence, suppuration may occur. There is then less pain; rigors may be experienced by the patient; and pus may appear in his urine. The discharge may take place in that direction; or it may present itself at the back;—giving the appearance of a lumbar abscess, perhaps. Sometimes, however, it has been known to open into the intestines. Various terminations have occurred; all of which we may imagine beforehand. The pus has sometimes been collected into an abscess; and sometimes it has appeared in separate portions;—forming so many minute specks, with which the organ has been studded.

*Treatment.*—The treatment of the disease consists in bleeding at the arm; cupping on the loins,—either alone or after general bleeding; purging, especially by calomel; putting the patient into a warm bath; and low diet. If the kidneys suppurate, it is necessary to treat it as any other suppuration. We must support the strength; tranquillize the patient by anodynes; and perhaps give "*uva ursi*." Some recommend this drug; but whether it has any particular virtue, I do not know. The common treatment of suppuration, in any part of the body, is that which is required.

## SECTION II.—HÆMATURIA.

*Causes.*—The kidneys are subject to hæmorrhage; and when blood appears in the urine, the disease is called "*hæmaturia*."<sup>a</sup> Blood may appear in the urine from an affection of the kidneys, or of the ureters, or of the bladder, or of the urethra, or of some other part opening into the kidney. The blood is occasionally diffused through the urine;—the urine contains a sediment, which is evidently a mass of blood; and sometimes blood is discharged without any urine.

*Diagnosis.*—If the urine be red in consequence of the presence of blood, I think we may always distinguish it by the eye. It is not of a deep orange-colour; but is of downright red. We may always distinguish it from the most red sediment, produced by feverishness and inflammation. It is a true red;—such as no one, I should think, can mistake; but if we have any doubt, we may dip a rag into it; and we shall find it stained red;—without any tinge of yellow, or any orange-tint;

<sup>a</sup> From *αἷμα*, blood; and *ουρον*, urine.

as is the case in the highest-coloured urine if no blood be present. Frequently blood is discharged so pure, or in such a quantity, that (independently of the colour) we ascertain its presence at once. But we have another point to ascertain. After having distinguished whether it is blood or not, we have also to find out whence it comes;—whether from the kidney, or some other part. If it be furnished by the urethra, the latter will present evident symptoms of disease. It is common in violent gonorrhœa, in stricture, and when a bougie is passed. There can be no difficulty, I think, in ascertaining whether the hæmorrhage comes from the urethra; the point most difficult to ascertain is, whether it comes from the *kidney* or from the *bladder*. It is rare for hæmorrhage to take place from the ureter.

I presume the mode of distinguishing between hæmorrhage from the kidney, and that from the bladder, would be by observing where the other symptoms reside;—whether in the loins, or down in the pelvis. Sometimes, I believe, it is impossible to take an accurate diagnosis. I recollect having a case of “*fungus hæmatodes*” of the bladder, which was productive of no pain, nor of any irritation whatever. The only symptom the man had, was a discharge of blood from the urinary passages. I could make out no disease at all. He died under the repeated hæmorrhages; and, at the autopsy, a fungus was found shooting from the bladder. But if there be any symptoms besides the bleeding, emaciation, and debility, we should observe whether they are situated in the *loins* or about the *bladder*. If they are in the *loins*, there will be pain there, most likely sickness, and perhaps tenderness in the region of the kidney. If the symptoms are in the *bladder*, we have pain about the pelvis, and a frequent desire to make water;—far more so than in the other case;—there will be far greater irritation. But it is to be remembered, that disease of the bladder and urethra will cause pain in the kidney; and that disease of the kidney will cause irritation about the bladder, as well as the symptoms I have mentioned about the testicle.<sup>a</sup> The latter show how distant the symptoms may be, when the kidney is itself affected; but, generally, the greater intensity of the symptoms at one spot rather than at another, will remove all difficulty.

*General Treatment.*—Hæmaturia is sometimes easily cured; or, on the other hand, it may be very dangerous;—all depends upon the cause. It is sometimes inflammatory, and is attended with a quick pulse, a dry tongue, and even retraction of the testicle. It will then give way to the common treatment for nephritis.<sup>b</sup> A bleeding or two, or purging, will generally get rid of it. When it is inflammatory, it is acute; and generally arises from some evident cause,—a “cold,” or a blow, or some acrid substances that have been taken. The most common of the latter (and, indeed, the only ones that I ever saw produce it) are turpentine and cantharides. When it has arisen from these, it would be well to take plenty of diluents and demulcent substances. Water, with a quantity of gum in it, and mucilaginous matters in general, should be employed in addition to anti-inflammatory treatment.

*Treatment of Passive Hæmaturia.*—Sometimes, however, this hæmorrhage is entirely passive;—not accompanied by any signs of inflammation. It sometimes occurs with typhus fever, sometimes with small-pox, and sometimes with “*purpura hæmorrhagica*,”—both in cases where that disease arises entirely from debility, as well as when it is inflammatory. In these circumstances the treatment for passive hæmorrhage must be adopted; and turpentine will be found very useful;—not in *large*, but in *small* doses;—from twenty to twenty-five drops, every four or six hours. Of course the system requires support; and the common treatment of passive inflammation must be adopted, at the same time that we employ this specific remedy.

*Arising from Chronic Disease of the Kidney.*—When hæmorrhage takes place in chronic disease of the kidney; when we have seen chronic disease previously existing; when we suspect the presence of calculi in the kidney, or a cancerous affection of the organ, or any other structural disease,—the same treatment must be adopted. We cannot, in general, lower the patient. If there be symptoms of in-

<sup>a</sup> See Page 969.

<sup>b</sup> See Page 970.

flammation, we must act accordingly; but, in general, the administration of turpentine in small doses (carefully watching it lest it should irritate the kidneys),—together with the exhibition of opiates to relieve the pain and procure rest, and giving the patient good support,—is all that is needful. The treatment will give no difficulty at all. We have only to treat it in the same way as we should treat hæmorrhage from other parts. Consider what is the patient's strength, on the one hand, or his debility, on the other;—consider whether there are symptoms of active inflammation, or how far the hæmorrhage appears to be passive only. If the disease be not inflammatory, oil of turpentine is of as great use here, as in hæmorrhage from the alimentary canal; but it is necessary that we should carefully watch the patient; because that which is *passive* to-day, may, through sudden excitement, be *active* to-morrow.

*Hæmaturia from suppressed Discharges.*—This hæmorrhage occurs, sometimes, in a curious way. Like other hæmorrhages, it has occurred where the menses have been suspended. I once saw an instance of its occurrence, after hæmoptysis had been cured. Occasionally it will take place in men, and also in women; but more frequently in men who have been subject to a discharge of blood from the hæmorrhoidal vessels. When that discharge is stopped, they are in the predicament of a woman who is in a state of amenorrhœa. Generally speaking, these cases are not dangerous; but they require antiphlogistic treatment. If the natural discharge of menstruation has ceased; and inflammatory hæmaturia has supervened, it may be right to attempt to bring it back again.

### SECTION III.—ORGANIC DISEASES OF THE KIDNEY.

*Hypertrophy.*—The kidney is subject also to *chronic* inflammation; but we usually see the effects of chronic inflammation in the form of organic disease. Occasionally the kidney becomes *enlarged*. There is no particular alteration of structure; but the organ is evidently *hypertrophied*, and is perhaps firmer than usual. I presume that over-nourishment is, more or less, of an inflammatory nature; and that, from the great activity of the circulation, deposition has taken place.

*Turgescence.*—Sometimes the kidney will become very *turgid*, and very *red*;—merely as the result of a difficulty in the circulation. Sometimes, after great dyspnœa,—after obstruction of the *heart*,—after obstruction of the *lungs*, the kidney, on being cut open, has been found full of blood;—so that we might, at first, mistake the appearance for that of active inflammation. But if there be active inflammation, the kidney is generally found *soft*; whereas the effect of chronic inflammation of this organ, is either induration or hypertrophy.

*Paleness.*—Frequently the kidney, instead of being red, is *pale*. After death has occurred from chronic disease, the body is generally found to be wasted; and not only are the *brain*, and the *muscles* pale, but the *kidney* likewise. The kidney, however, is sometimes pale through disease of its own; and then it is generally firmer and harder than it should be. When I mentioned induration as a common effect of inflammation, I spoke both of *red* and of *pale* induration,<sup>a</sup> and each of these kinds occurs in the kidney.

*Mottled Kidney.*—But the kidney is sometimes very red, or very pale, only in *spots*; and then we have what is called “a *mottled* kidney.” Morbid paleness usually occurs in the cortical part; but sometimes the whole kidney is in this condition. Hypertrophy, attended with redness,—when it is partial, occurs in the cortical portion; and that also will give rise to a mottled appearance. We may have a mottled appearance from one part becoming morbidly pale, while the other remains natural; or it may arise from one part becoming morbidly red, while the other retains its natural paleness.

<sup>a</sup> See Page 176.

*Granular Kidney.*—Occasionally the kidney is *granulated*. Small grains, more or less firm, are seen in different parts. Whether this is local hypertrophy or not, I do not know; but it is found most frequently in the cortical portion. These grains are of all numbers, and of all sizes.

*Softening.*—Occasionally the kidney becomes excessively *soft*; so that we may break it up with our fingers; and this, I presume, may occur very rapidly. I have no cases in point to support this opinion; but, judging from what occurs in the spleen and liver, I should think that the softening may be very rapid. I know that softening of the spleen or liver, will take place in the course of a few days. A person, in perfect health, may be suddenly taken ill and die; and we shall find these parts so soft, that we can run our finger through them in every direction,—break them up in a moment; and therefore I can conceive that the kidney may become soft either in an *acute*, or in a *chronic* way. When this organ is soft, there is the usual difference;—that is to say, the softness is sometimes accompanied with redness, and sometimes with paleness. Sometimes there is *inflammatory* softening; and sometimes this change appears to take place without any connection with inflammation.

*Atrophy.*—The kidney will sometimes *waste*. If one kidney waste, it is usual for the other to double its natural size;—in order to perform the duty of both. Nothing is more common, than to find one kidney enlarged, in proportion as the other is diminished. This wasting of the kidney will sometimes proceed to such an extent, that we can scarcely find any remains of the organ. I have met with cases where the kidney was discovered with the greatest difficulty; so that those who have first examined the body, have said that there was but one kidney. What is termed “a *horseshoe* kidney,” is where there is only one. That, however, is a rare case; but the organ is sometimes wasted to a less size than that of a horse-bean. Atrophy of the kidney sometimes takes place, without any ascertainable cause. Sometimes it is the result of inflammation; sometimes it is the result of abscess. A great discharge will cause atrophy of part of the organ. We produce counter-irritation, for the purpose of lessening morbid growths, and morbid activity of the circulation; and if, without morbid growths and morbid activity, a discharge takes place by suppuration, the activity of the part is diminished, and wasting is a very common circumstance. An abscess, therefore, will occasion a part to waste; according to the general principles on which we employ setons and issues. But pressure will have the same effect. The pressure occasioned by a tumour in the neighbourhood of the kidney, has been seen to produce atrophy of the organ. It is stated, by authors, that atrophy of the kidney is sometimes partial; so that the medullary portion only is wasted, and the pelvis becomes a mere bag. Sometimes the *cortical* part is wasted; so that the cones within the kidney nearly touch the external fibrous membrane;—there being only a thin layer of cortical substance between. Thus, we see, there are various degrees of atrophy; and they have all been considered as a frequent result of inflammation.

*Serous Cysts.*—We have, however, other organic disease of the kidney. In the cortical substance, serous cysts are very common; and, by their pressure and growth, they will cause an atrophy of it. As they increase, they cause more and more atrophy; till there is little more than a bag left. Cruveilhier has given a very good representation of these cysts. They are found more commonly in the kidney and liver, than in any other parts of the body. Serous cysts are sometimes found under the external membrane of the kidney.

*Fatty Degeneration.*—The kidney has sometimes been seen converted to fat. A great deposition of fat, I presume, has taken place in the cellular membrane, under the external coat; and the rest has wasted. Sometimes it has been converted into *jelly*. A peculiar substance of this kind is occasionally formed in the kidney, which sometimes contains a great quantity of it;—causing atrophy of the organ itself.

*Malignant Disease.*—Occasionally *encephaloid* disease occurs in this part. We

may have great *disorganization* of the kidney;—we may have *tubercles* of various kinds; and even *scrofulous* tubercles have been found here.

*Symptoms of Organic Disease.*—All these diseases may occur with very obscure symptoms; but sometimes they occasion dull pain in the region of the kidney, together with more or less disturbance of the stomach. The diagnosis is generally difficult; unless the pain be very local, and the urine very much affected. Even then,—when we have satisfactorily made out that there must be organic disease,—it must be very difficult, if not impossible, to say what that organic disease is. Scirrhus is said to occur in the kidney; but whether the affection is scirrhus, cancer, encephaloid disease, or a mixture of these, or a scrofulous suppuration, it must be difficult to determine. If organic disease occur in a young person, and there is not much pain, we may suspect that it is encephaloid. If there be strong marks of scrofula;—if the ends of the fingers be enlarged;—if there be mesenteric disease, or phthisis,—we may suspect that the affection of the kidney is of a scrofulous nature. If the person be advanced in life, we may suspect scirrhus or cancer. The particular nature of the organic alteration, however, can make no difference as to the treatment; which must be conducted on general principles. Dr. Baillie states that, according to his observations, the kidneys are more frequently affected in *men* than in *women*.

*Diseases of the Renal Capsules.*—The renal capsules are rarely diseased, except from scrofula; but I have frequently seen them in that condition. Sometimes they are indurated; and the induration may amount to cartilage, or even to bone. As to the symptoms, nothing can be said on that subject.

---

## CHAPTER II.

### FUNCTIONAL DISORDERS OF THE KIDNEY.

HAVING spoken of those diseases which are the result of *inflammation* of the kidney,<sup>a</sup> and of *structural* diseases,<sup>b</sup> I will now proceed to consider *functional* disorders of that organ. The kidney is subject to an *increase* and to a *diminution* of its secretion. It is liable to secrete *morbid* urine;—to secrete a substance which it ought not to form in that particular way; or which, if it be produced, should pass off with the urine. Besides these affections, the urinary organs are sometimes infested by worms.

#### SECTION I.—ISCHURIA.

*Varieties.*—The first disease which I shall mention, is a diminution of the secretion; and this is called “ischuria.” The *suppression* of urine, the *absence* of urine, or the *diminution* of urine, when it occurs in the kidney, is called “ischuria *renalis*.” If urine be found in the kidney, but cannot escape from it, owing to some obstruction in the *ureters*,—then it is called “ischuria *ureterica*.” If there be some obstruction in the *bladder*, it is then termed “ischuria *vesicalis*.” If there be obstruction in the *urethra*, it is denominated “ischuria *urethralis*.” There is no analogy in these different words. If the urine be *suppressed*,—that is to say, if none be *formed*,—we call it “*suppression* of urine;” if, however, it be formed, but cannot *escape*, we call it “*retention* of urine;” so that “ischuria *renalis*” and “ischuria *vesicalis*” are not at all analogous; and young beginners are often laughed

<sup>a</sup> See Page 969.

<sup>b</sup> See Page 972.

at in the hospital-wards, for saying "*suppression*," when they ought to say "*retention*," and *vice versa*.

*Symptoms.*—The *suppression* of urine,—a deficiency of the *secretion*,—may be entirely inflammatory; and then we have symptoms of nephritis,<sup>a</sup> and must treat it as inflammation.<sup>b</sup> But sometimes this complaint is unconnected with any symptoms of inflammation of the part; and it certainly is then a curious affection; for it is usually followed by apoplexy. No urine is made, or scarcely any; and, at last, absolutely none. There is no fulness of the bladder; and when we pass an instrument,—to ascertain whether it is a case of retention or not,—we find that the organ is empty. In general, the patient very soon becomes drowsy; which drowsiness increases, till he becomes decidedly apoplectic, and perhaps dies. In the "London Medical Dictionary," Dr. Parr mentions a case, where no urine was made for six weeks; and Haller quotes an instance, in which it was said that no urine formed for twenty-two weeks. These are very chronic cases; and one cannot answer for the truth of that which Haller alludes to. I presume he mentions it on the authority of another. The disease has sometimes been ushered in with rigors, and sometimes not. Sometimes it has occurred without any particular symptom, till coma has made its appearance. Following the course of diseases of the kidney, it occurs more frequently in men than in women.<sup>c</sup> It usually takes place in fat people; and especially in those who are upwards of fifty years of age.

*Excretion from other Organs.*—When the urine has been suppressed in this way, it has occasionally escaped from some other part of the body; and when the urine has *not* been suppressed, but (though formed) has not been able to escape,—in consequence of some obstruction,—it has been absorbed; and has passed off by some other organ. I know instances where it has been *vomited*; and I saw a case where it passed from the *skin*,—particularly the palms of the hands. Persons in these circumstances,—who have made no urine, or whose urine (when secreted) could not escape,—have occasionally vomited a fluid, which had the smell, and taste, and all other qualities of urine. Others have passed it in the form of perspiration. There can be no doubt of the truth of these cases. I presume that, in the latter case, the fluid has been absorbed, and re-secreted; and, in the former case, it has been secreted originally, and has not been absorbed at all.

*Termination in Apoplexy.*—In "*ischuria renalis*," it is very common for the individual to become apoplectic; and it is, therefore, a very dangerous disease. I have had but one case of it, and that occurred after a person had taken (by mistake) a quantity of corrosive sublimate. Proper means had been used, and no harm was thought likely to occur; but, after a certain time, the urine became suppressed. I think the individual had hemiplegia; but I recollect perfectly, that he became drowsy; and the drowsiness increased till, at length, he became decidedly apoplectic, and died. One might imagine, in such a case, that the same occurrence must have happened as when the urine has been vomited, or has been thrown off by perspiration;—namely, that the urine was re-secreted into the ventricles of the brain; or that, if no urine was secreted, that an excessive quantity of *fluid* would be found within the brain. Nothing of the kind, however, was discovered in this case. There was not only no *urine* in the head; but no excess of *fluid*, either *in* or *upon* the brain. That was a result for which we were not prepared.

*Treatment.*—The proper mode of treating these cases is to give cantharides. I do not know whether oil of turpentine has been tried. In the case I saw,<sup>d</sup> a blister was applied, and cantharides were given internally; but the patient died within a few hours of its exhibition. However, a friend of mine had two cases which occurred nearly together, in old people; and one of them was so bad, that Sir Astley Cooper, who was called in, had little hope of saving life; but he treated the case in a way which, he said, had been found successful; and the patient got perfectly well. In the second case, my friend adopted the same plan; and it was attended with the

<sup>a</sup> See Page 969.

<sup>c</sup> See Page 974.

<sup>b</sup> See Page 971.

<sup>d</sup> See the previous Paragraph.

same success. In the latter case, it appears that the kidney had become torpid; but not through inflammation. Whether other diuretics would answer, I do not know; but it is said that cantharides should be given internally, and a large blister applied to the loins,—in order that the medicine may have more effect; because the surface has much influence over the internal parts. When it is exhibited internally, it should be in the solid form; because the tincture is a most uncertain preparation. We should give a grain once or twice a day, or every eight hours; whichever we choose. A grain is a pretty strong dose; but, in a case of this description, there is no time to be lost, for apoplexy may soon come on; and therefore we should repeat the dose, as long as it does no harm. I have given ten, fifteen, or twenty drops of the tincture, without any effect; and, at last, I have been obliged to give two or three drachms. The tincture, I presume, was not good; but it has been so common an occurrence, with me, to find the tincture either bad from its nature, or bad from its being so continually ill made, that I place no confidence in it, in a case of life and death, where there is no time to be lost.

## SECTION II.—DIABETES.

*Etymology.*—The term “*diabetes*” is derived from the Greek word διαβαίνω, —to stream through;—the disease being characterized by the “streaming away” of a considerable quantity of water. This affection, on account of the excess of fluid, has sometimes been called “*hydrops ad matulam*,”—“chamber-pot dropsy;” but as there is an accumulation of fluid, it cannot, without great impropriety, be called “*dropsy*.” In dropsy there is an accumulation of fluid;—not merely a formation of it. It is formed faster than it comes away, and therefore is termed “*dropsy*,” but as, in diabetes, the water comes away, the word *dropsy* has been applied to it with the greatest absurdity.

*Definition.*—The word “*diabetes*” is usually employed to signify chronic excess of urine. A person would not be said to have diabetes, if he merely made a large quantity of urine for a day or two. The fluid may be either of a natural quality, or it may contain sugar. As, however, there is no distinct single name for that disease in which sugar is formed in the urine, and as it is sometimes formed without the urine being at all in excess, it would be well, perhaps, to restrict the term “*diabetes*” solely to *saccharine* urine, and to give such a name as “*polyuria*”<sup>a</sup> to that form of the disease, in which there is merely excessive quantity. But we find “*diabetes*” employed to signify a chronic excess of urine, whether there be sugar in it or not;—the one being called “*diabetes insipidus*,” and the other “*diabetes mellitus*,”—“*honey-like*,”—sweet to the taste. It was to an excessive quantity of urine, that the ancients applied this term; for it does not appear that they were at all aware, that the urine was ever sweet. I believe it was Dr. Willis, the English physician, who first pointed out that, in this disease, the urine is sometimes saccharine. The term is certainly employed by the ancients simply to denote a chronic excess of urine.

*Excess of Urine in Various Diseases.*—There is frequently a temporary excess of urine, in various diseases. In asthma, for example, a large quantity of pale urine is frequently made. So, again, in hysterical and dyspeptic people, this is often the case. Fright likewise will cause a temporary excessive quantity of urine; so that persons who have been waiting anxiously to be called into a room, have been obliged to walk out twenty times in the course of an hour. Long-continued grief and anxiety have the same effect. I have known persons, from leaving off some of their clothes, make a considerable quantity of urine; and it has been remedied by wearing their usual quantity of clothes again.

*Diabetes Insipidus.*—But, independently of the circumstances I have now mentioned, there is sometimes formed an excessive quantity of urine; not at all

<sup>a</sup> From πολυς, much; and ουρον, urine.

impregnated with sugar, and occurring without any evident cause. This form of the disease,—which (as it sometimes has been) might as well be called “polyuria,”—is occasionally followed by that form in which the urine contains sugar. But sometimes it exists alone; and I believe that, not unfrequently, after a length of time, it will cease. This incipient diabetes is more common in women, than in men. The urine is very pale, in general; and if it continue, thirst and dryness of skin are mechanically produced. An excessive secretion of water is going on in one part of the body; and there is therefore less water for the secretion of the mouth and skin. From the loss which the body sustains, there is also weakness and hunger. This condition may frequently be recovered from, by wearing warm clothing, employing the hot-bath, or going to a warm climate; and by the exhibition of iron. Persons who have laboured under this form of the disease have, by medical men who have not properly examined the urine, been said to be cured of diabetes; as though they had had the saccharine form of the disease.

*Diabetes Mellitus.*—In “diabetes mellitus,” or *true diabetes*, there is sugar in the fluid; and generally there is also an excessive quantity of fluid. The general symptoms that I just now mentioned, are produced in this affection. From the loss which the body sustains, there is great debility; from the body losing its nourishment, there is hunger; and from the want of fluid, there is thirst and dryness of skin. The hunger is sometimes excessive; so that the patient not only feels very hungry at the usual time of his meals, but he feels hungry during the greater part of the day. The food which the patient takes, does him (he says) “no good;” and he is presently anxious for more. Patients generally complain of a sinking at the pit of the stomach; and the uneasiness there occasionally amounts to aching. The thirst is sometimes so great, that many quarts of fluid are drunk in the course of the day; and the skin is sometimes so dry, that the hair falls off. The feet and hands are frequently cold; there is lowness of spirits; and, in almost every case, peevishness and fretfulness. There is also one very remarkable symptom;—the loss of sexual power and desire. I have never found this symptom absent; and sometimes it has been the very first symptom noticed by the patient. I never had a patient labouring under diabetes, in whom the feeling of sexual power and desire had not ceased entirely, or become very much impaired. This symptom is not noticed by all authors; and a patient, of course, will not mention it; but, on making a point of inquiring into it, we shall (I believe) nearly always find it to be a fact. There is also frequently pain of the loins; but whether it arises from an affection of the kidney, or is merely a symptom of debility, I do not know. Although the whole body becomes emaciated, there is frequently œdema of the legs; and usually there is costiveness. From the deficiency of fluid in the alimentary canal, there is not only dryness of the skin, and thirst, but the tongue is sometimes white and clammy. Frequently, however, it is smooth and red; and the saliva and mucus are excessively tenacious;—so that the patient is very much annoyed. The gums sometimes become very red, and slightly ulcerated. The saliva is occasionally sweet; and so likewise is the breath. Dr. Latham says, that the body smells like hay. I have not observed this; but the breath frequently has sweet smells;—has something of the odour mentioned by Dr. Latham. Very often there is redness and soreness of the end of the urethra. I have seen even phimosis;<sup>a</sup> which may arise, perhaps, from the irritating quality of the fluid. We usually find the pulse quick,—perhaps full; and at last it becomes weak. There is a hectic appearance in the patient’s face;—we frequently find a flush upon his cheek, as well as quickness of the pulse; and, at last, we have decided hectic. In many cases there is great sweating,—I have frequently seen it. Phthisis is a very common termination of this complaint. Indeed, the majority of diabetic patients whom I have attended, have died of phthisis. The urine has a particular odour, which is not perceived by smelling the pot; but if we partly fill a phial with it, and keep it

<sup>a</sup> From φῑμω, to tie up.

corked for a little time, on withdrawing the cork, we may perceive a peculiar smell, —something like peppermint. It has also a sweet taste; which we may ascertain by desiring the patient to taste for himself. Generally the urine is clear, and of a lemon-colour. Besides the presence of sugar, there is usually a diseased secretion altogether.

*Quantity of Urine voided.*—Professor Frank, of Vienna, saw a case in which, on an average, forty pints of urine were made in a day. There were sometimes as much as fifty-two pints. He says that other authors have mentioned fifty-two pints being discharged. He also states that he saw a case, in which the quantity voided, in a few days, exceeded the whole weight of the body. Usually, however, the quantity of urine discharged, is from six to twenty pints *per diem*. On the other hand, the urine is sometimes very little increased in quantity; and sometimes not at all. Professor Frank mentions a few cases of this disease, where the quantity was not increased; but it contained so much sugar, that from two pints of fluid six ounces of saccharine matter were obtained. One patient of mine made, at last, but three pints of urine in a day;—which was less fluid than he drank. Dr. Heberden mentions a case, in which the urine made was double the quantity of the fluid drunk. Such are the varieties as to the quantity of urine.

*Quantity of Sugar.*—With regard to the quantity of saccharine matter, Dr. Dobson procured an ounce of saccharine extract, by evaporating a pint of urine. Cruikshank obtained three ounces and a quarter from thirty-six ounces troy; and found the specific gravity to be 1.040. From ten pints of urine, he obtained a pound and a quarter of solid extract. Dr. Prout, from a pint of urine,—the specific gravity of which was 1.050,—obtained two ounces of thick stuff; and from this he procured one ounce and a half of sugar. Frank says that, from twenty-four pints of urine, he obtained twenty-six ounces of saccharine extract. The sugar obtained from urine, is like that procured from grapes.

*Fermentation of the Urine.*—From the presence of sugar, the urine undergoes a vinous fermentation; so that, at a certain time, if it be thrown into the fire, it burns;—just as if it had been spirits. Still later, the urine becomes quite sour. The usual changes which sugar is capable of producing go on; that is to say, we have vinous and acid fermentation.

*Deficiency of the other Constituents.*—These, however, are not the only circumstances in this disease; for there is frequently but little urea in the urine:—little lithic acid, and little of the usual salts. Not that they are *absent*; for I saw them all myself in a patient's urine, which contained a large quantity of sugar. But it is said that, in general, they are very *deficient*; and deficient in proportion to the quantity of sugar formed.

*Specific Gravity of the Urine.*—The weight of the urine, in this disease, depends upon the quantity of sugar; and the quantity of sugar is such as to augment the weight very considerably. The specific gravity of healthy urine is generally from 1.010 to 1.018; but that of *diabetic* urine is from 1.030 to 1.050; and I think I have seen it still higher. This excessive weight, as I have just said, depends on the presence of sugar.

*Cause of the Presence of Sugar.*—It has been supposed, that the presence of the sugar is dependent upon the deficiency of urea; and urea and sugar contain exactly the same quantity of *hydrogen*; while the quantity of *carbon* and *oxygen*, in sugar, is twice that of those substances in urea. It has therefore been supposed, that there is only a morbid change undergone in the composition of the urine;—that instead of *urea*, we have *sugar*. However, this is certainly not accurate; because I have seen a large quantity of sugar in the urine, where there was likewise a considerable quantity of urea. Still, it frequently does happen that, in proportion as the one is deficient, the other is abundant. It is by no means proved, I think, that sugar is merely altered urea; and those have mistaken the matter who say, that urea is absent in diabetic urine; for sometimes a large quantity of urea is found in true diabetes; where, of course, there is a large quantity of sugar.

*Reappearance of Albumen.*—If the disease take a favourable course, Dupuytren and Thenard assert that, before the salts and urea appear again, albumen is found. Dr. Prout mentions, that the worst form of diabetes is where the urine is albuminous;—where, besides sugar, we find albuminous flocculi in the urine. In a fatal case of mine, not long before death, there were albuminous flocculi. These flocculi increase the fermentation, which the urine experiences from the sugar.

*Condition of the Blood.*—It is pretty certain that no sugar is found in the *blood* of these patients. Dr. Prout, who is very nice in his examination of these things, says that he has sometimes seen something *like* sugar; but *true* sugar has been looked for, by a large number of chemists, in vain.

In this disease, the blood is sometimes of an unnatural appearance. It is said, by Dr. Watts, of Glasgow, (who, I dare say, may be depended upon,) to be a little like treacle, and of a bluish colour; but this is not an invariable circumstance; for I have not noticed it myself. The serum of the blood had a white fluid swimming upon it; and the blood was buffed. I mention this to show, that we may have these things, at the same time that the urine contains sugar. There is no connection between them; only the presence of one does not exclude the possibility of the other being present also. I may mention that Vauquelin found no sugar in the blood of a person, whose urine actually contained one-seventh part of sugar. He also says that he found no *urea* in the blood of this individual; though he gave him a large quantity by the mouth, for some days. He also states that an opposite occurrence takes place here, to what is observed in scurvy;—namely, that the blood will not putrefy so soon as in health. In one case of my own,—the only case (I believe) in which experiments were made,—it was found that the more sugar the urine contained, the larger was the quantity of carbon discharged from the lungs.

*Duration and Termination.*—This disease may last many years; and it may prove fatal by phthisis;—that is to say, it may induce phthisis, or be followed by it. The fact may be expressed in any way we choose,—diabetic patients frequently die phthisical. They sometimes die from mere exhaustion, occasioned by the disease; and sometimes they die suddenly; but the most common terminations are phthisis, and mere exhaustion. It may destroy a patient in a year or two, or it may remit; and I believe it may cease, or be cured. Dr. Gregory<sup>a</sup> used to say that he knew a case, where the saccharine quality of the urine ceased in two days, and did not return; but whether the observations were made with all the accuracy that we require, in modern times, I do not know. Usually the appearance of sugar, and the excessive quantity of urine, decline together;—that is to say, in proportion as the quantity of urine becomes less, so does the proportion of sugar. We may have the quantity of urine diminished, and yet the proportion of sugar to that quantity remain the same, and, on the other hand, it is asserted (though I have not seen it) that the sugar sometimes diminishes in absolute quantity, while the urine remains in the same excess as before. As, however, the sugar absolutely lessens, so do the salts, the lithic acid, and the urea, generally increase. The colouring matter of the urine is usually deficient, as well as the lithic acid and salts; and sometimes the sugar entirely disappears before death. I have seen the urine, in diabetic patients, suddenly cease to have a particle of sugar in it; and yet the patient has died in the course of three or four days.

[With respect to the *terminations* of diabetes, phthisis (as already stated) is the most frequent. Besides phthisis, however, I have seen diabetes prove fatal by disease of the liver and jaundice, by apoplexy, by a peculiar affection of the stomach, brought on by improper food, or by over-distension; by acute gastritis induced by taking cold fluids when heated; by inflammatory fever excited by exposure to cold, and rapidly assuming the typhoid character, &c. Occasionally diabetes is said to terminate in incurable dropsy, and in various other affections. In short, a great many circumstances which would not affect a sound constitution, often prove fatal in this disease. Hence a diabetic individual may be considered

<sup>a</sup> See Note to Page 239.

as existing on the brink of a precipice; and the general prognosis must be always unfavourable.<sup>a</sup>]

*Morbid Appearances.*—After death, we frequently find no morbid appearances whatever. I have several times opened diabetic patients; and, as far as I could judge, the whole of the body was sound. The kidneys have sometimes been enlarged a little;—sometimes a little redder or fuller than natural, and a little flabby; but that has been all; and sometimes I have not seen even that. The ureters are said to be sometimes florid; but Morbid Anatomy alone certainly gives us no explanation of this disease. Suppose we find the kidney fuller or larger than natural, and the vessels more distinct, that is nothing more than we should expect, from the kidney being stimulated to excessive action; and, whatever may be the cause, that appearance of the kidney certainly does not explain the saccharine quality of the urine.

*Causes.*—[It is a remarkable fact, that diabetes seems to be peculiar to mankind. Horses and other animals are, indeed, subject to diseases accompanied by a large flow of urine; but I am assured that in such cases the urine is never saccharine; nor am I aware that sugar has been found in the urine of any inferior animal. If such an immunity from diabetes really exists among the inferior animals, its cause is very obscure. Can the exemption be referred to the absence of that fertile cause of bodily disorder in human beings, the influence of *mind*?<sup>b</sup>]

*Predisposing Causes.*—Diabetes is by no means confined to adults; for it frequently affects children also; but it is not so easily observed in them. It occurs much more frequently in men, than in women; and it occurs much more frequently in some countries, than in others. Professor Frank says, that he saw but three cases of it in Germany, for twenty years; and that when he practised in Italy, he saw but seven cases in eight years. There are far more cases of it in Edinburgh, than in London. When I was a student in Edinburgh, there were always some cases of it to be found; but I do not recollect having a case in London, for two years.

*Exciting Causes.*—Sometimes it is produced by grief. I have seen it produced by the long continuance of the depressing passions. It is sometimes occasioned by chills;—by the exposure of the body to heat and cold alternately;—especially when the body is in a state of perspiration. It sometimes appears to arise from strains of the loins. Whether whiskey has any power in producing it, I do not know; but it is far more common in Scotland, than in England. I suppose they drink as much whiskey in Ireland, as in Scotland; but whether the disease is equally prevalent there, I do not know. Dr. Latham says, that he has seen the disease come on after boils; and I have heard others, I think, confirm the observation. Excess of venery appears likewise to be a cause of it. Some authors mention this most decidedly, as the cause of the disease; and, in some instances, I have asked the question of young men; and they have replied that they had indulged to great excess. Whether they had or had not, I cannot say; because people feel differently as to what is excess. I saw it, however, in one man, who had committed no excess of this kind; for he said he had never “known a woman;” but he died of the disease; and it is very possible he had committed excess of a less creditable kind. I rather think this was the case, from the great length of the prepuce. Sometimes there is no evident exciting cause at all; and, in some cases, it is evidently constitutional and hereditary. One German writer mentions having seen seven cases of the disease in one family. Dr. Gregory<sup>c</sup> said that he saw three cases in one family; and Dr. Prout knew a mother, an uncle, a brother, and a sister, all affected with the disease.

<sup>a</sup> Dr. Prout, on the Nature and Treatment of Stomach and Urinary Diseases. Third Edition; Pages 33 and 34.

<sup>b</sup> Dr. Prout on the Nature and Treatment of Stomach and Urinary Diseases. Third Edition; Page 34.

<sup>c</sup> See Note to Page 239.

*Pathology.*—Some declare the disease to be situated in the kidney; while others maintain that it is situated in the stomach. Many of the symptoms are as easily explained on *one* supposition, as on the *other*. The thirst and the dryness of skin are referable to the loss of fluid. So, again, the costiveness, the emaciation, the hunger, the debility, and the sensation of sinking at the stomach, are all referable to the mere loss of so much substance, as must be lost in the production of sugar. But the absence of sugar in the blood, and the very frequent absence of dyspepsia, or any thing connected with the stomach, except the hunger (which the excessive loss will explain), make it appear to me most probable that the disease is situated in the kidney.

[The *proximate* cause of diabetes has much puzzled physiologists; and a great deal has been said and written on the subject, which it would be useless to repeat here. According to the principles<sup>a</sup> advanced in this volume,<sup>b</sup> the proximate cause of diabetes lies partly in the assimilating organs, and partly in the kidneys; and may be thus stated:—

When *crystallized* sugar is taken into the stomach by a diabetic individual, it is reduced to a *low* state, remains more or less unassimilated, and passes through the system to the kidneys; by which organs (being already crystallizable) it is separated unchanged.

When *organized* saccharine principles,—as farinaceous matters, &c.,—are taken into the diabetic stomach, they are (in the first place) reduced to the form of *low* sugar; part of which is assimilated, as in the healthy stomach; while another part is modified, or remains unassimilated. The portion that is assimilated is applied to the purposes of the economy; the portions modified and unassimilated, pass together through the system to the kidneys; by which glands the portion modified is disorganized, and finally appears in the urine as crystallizable sugar, along with the portion originally remaining unassimilated in the stomach. The same remarks are applicable to gelatinous, and in extreme cases, perhaps, to albuminous and oleaginous aliments. The *secondary* assimilating processes in diabetic individuals, participate in the derangements of the primary processes just detailed;—that is to say, the gelatinous tissues are either reduced to sugar, and thus not assimilated at all; or they are imperfectly assimilated; or they are mal-assimilated; in all which conditions, the saccharine principle derived from the gelatinous and other tissues, may be supposed to pass through the system to the kidneys; by which organs, like similar matters brought from the stomach, the various modifications of the saccharine principle are further disorganized, and converted into crystallizable sugar.<sup>c</sup>

Such are the modes in which the phenomena of diabetes appear explicable on our principles. I<sup>d</sup> shall not trouble the reader with corroborative details; but shall mention only one circumstance illustrative of the subject, on account of its practical importance. When, in diabetic individuals, the disorganizing function of the kidneys is suspended; or when these glands are partially diseased, the urine, besides albuminous matters and more or less of crystallizable sugar, often contains the saccharine principle in *imperfectly developed forms*. Hence the urine, almost without perceptibly becoming vinous, passes at once into the lactic or acetous fer-

<sup>a</sup> The principles alluded to, as far as they are involved in the present question, may be thus briefly recapitulated:—1. The assimilation of the saccharine principle is a distinct function. 2. The cellular tissue represents the saccharine aliment. 3. A secondary assimilating process, analogous to that in the digestive organs, is constantly going on in all parts of the body. 4. An important function of the kidneys is of a disorganizing character; that is, consists in the reduction of organized into crystallizable compounds.

<sup>b</sup> "On the Nature and Treatment of Stomach and Urinary Diseases; being an Inquiry into the Connection of Diabetes, Calculus, and other affections of the Kidney and Bladder with Indigestion. By William Prout, M.D." Third Edition.

<sup>c</sup> These views seem to be almost demonstrated by the important observations of Mr. M'Gregor; who found, that sugar is not only developed from vegetable and animal matters in the stomach; but that it exists in the blood, saliva, &c., and even in the alvine evacuations of a diabetic patient.

<sup>d</sup> Dr. Prout.

mentation; and acquires, from the quantity of lactic and acetic acids developed, the strong acrid smell of sour milk.<sup>a b</sup>]

*Diagnosis.*—The diagnosis is sufficiently easy. It may be made by measuring the quantity of fluid, by weighing it, and by analyzing it. We obtain, in diabetes, a brown treacly extract; which, on tasting, we find to be sweet. No one can object to taste it; for it is not urine, but sugar. When the fluid is evaporated, there is nothing left but “hard-bake;” which tastes just as well as any other “hard-bake.” But although the disease is made out easily enough, when we suspect its existence, and it really does exist, yet it is a disease which is continually overlooked. It comes on so insidiously, that many persons have it for a length of time, before the medical attendant suspects its existence. The patient complains of being weak and languid; does not know what is the matter with him; and the quantity of urine may not be such as to attract his attention;—so that frequently no light is thrown on the disease. I have known so many cases of this kind passed over, that when I see a patient complaining of weakness, and can discover no evident cause, I always question him as to the quantity of urine. Not long ago, I saw a patient who must have had diabetes for some years; but that circumstance never struck my mind. He had disease of the heart, which was killing him; and it was not till I saw him three or four months afterwards, that he spoke of the quantity of his urine. The disease of the heart explained every symptom of which he complained; but, upon being told that there was something wrong in his urine, I evaporated a portion, and found it was diabetic; and he then stated that, for several years, he had made an excessive quantity of urine. No disease is more easily passed over;—unless the patient chances to mention, that he makes a larger quantity of urine than usual. When we see a patient emaciated, complaining of thirst, with a good appetite, and a dry skin; while we can see no reason for these symptoms, either in the chest or abdomen,—it is well always to inquire into the state of the urine.

*Prognosis.*—[The general *prognosis* in diabetes, must be considered unfavourable. Among the *favourable* symptoms in this affection may be enumerated a moderate flow of urine, of a specific gravity not higher than 1·035; the appearance in the urine of lithic acid, either in its amorphous or crystallized form; the recent appearance of the disease, and absence of thirst; the retention or gain of flesh and strength; and (more than all) immunity from organic disease, especially of the lungs. On the contrary, when the flow of urine is permanently excessive, and of high specific gravity; or when this secretion is pale-coloured, opalescent, and serous; when the thirst, emaciation, and debility are extreme; or when organic disease, particularly of the lungs, is present, the chance of recovery is much diminished. But when (as is too frequently the case) several, or all of these unfavourable symptoms coexist, the chance of recovery is not only diminished, but *absolutely hopeless*.<sup>c</sup>]

*Treatment.*—Perhaps this is the most singular disease in the animal economy; for the nature of it is not known; and the treatment which is found useful is as singular as the disease itself. The remedies are directly opposite. There can be no doubt that repeated venesection has sometimes lessened the symptoms very much; and it is sometimes borne remarkably well. There are on record a sufficient number of cases to establish the fact, that bleeding is occasionally very useful in the disease; not bleeding to syncope,—not *violent* bleeding; but *repeated* bleedings,—taking from eight ounces to a pint. I have employed this method; and have seen it borne in a remarkable manner. In many cases, the urine diminished, and the quality improved, while venesection was going on. But though there can

<sup>a</sup> This phenomenon is often exhibited by the chylous urine;—a disease in which the disorganizing function of the kidneys is either destroyed, or suspended. (See Page 1050.)

<sup>b</sup> Dr. Prout, on the Nature and Treatment of Stomach and Urinary Diseases. Book 1; Chapter 2; Section 1; Subdivision 3. (Third Edition; Pages 26 to 38.)

<sup>c</sup> Dr. Prout, on the Nature and Treatment of Stomach and Urinary Diseases. Book 1; Chapter 2; Section 1; Subdivision 4. (Third Edition; Pages 38 and 39.)

be no doubt of its utility, yet it has frequently failed. Some prefer the application of leeches to the epigastrium; and some, cupping on the loins.

*Animal Diet.*—Then, again, rump-steaks eaten abundantly (which is a practice directly opposite to bleeding) have also answered as good a purpose. Many persons have their urine improved, by being confined to animal diet; but still, we should imagine that this would not go to the root of the complaint, wherever it may be. It is like giving phosphate of lime in softness of the bones, and taking carbonate of soda to remedy acidity of the stomach;—it is merely *alleviating*, not *curing* the disease. But we find it very difficult to make a person adhere to animal diet. He becomes so disgusted with it at last, that he says he would rather starve than eat meat every day. I never found a patient able to continue it for a length of time. Still, as there is great weakness, it may be well to make a patient live on meat as much as possible; and we find as strong evidence in its favour, as in that of bleeding.

[Dr. Francis Home was the first to point out the advantages of an animal diet, in the treatment of diabetes; but the dietetic treatment was not reduced to a regular system, or its effects thoroughly understood, till the publication of the interesting treatise of Dr. Rollo.\* This author illustrated the beneficial effects of animal diet by a variety of cases, in one of which a complete and apparently permanent recovery was accomplished; and since his time, a diet more or less purely animal has constituted an essential part of every successful method of cure. Dr. Rollo dwelt strongly on the necessity of enforcing for some time a strictly animal diet, into which no article of vegetable food was to be admitted. It has been found, however, exceedingly difficult to secure the observance of an absolute animal diet even in private practice, and still more in hospitals; and in recent times it has even been maintained, that the rigorous observance of such a diet is not essential; and that some articles of vegetable food, more especially bread, may be safely allowed in moderate proportion. The difficulty of enforcing a rigorous animal diet, must be readily conceded: the craving for vegetable aliments soon becomes overpowering, particularly where the patient is tantalized by the sight of others indulging in them without control. But some doubt may be entertained whether the rigour of Rollo's dietetic system can be relaxed at all without prejudice; even although several eminent authorities, and among the rest Dr. Prout, have decided the question in the affirmative. It is at least not unworthy of remark, that those who allow a moderate proportion of vegetable aliment, admit their practice to have been unsuccessful; while others, who maintain, with Dr. Bardsley, that a fair proportion of cases may be cured, have adopted in their practice a rigorous animal diet; and insist, like Rollo, that they who deny from their own experience the curability of the disease, had forfeited all claim to do so, from having permitted a departure from his injunctions in this respect.

It is universally conceded that, if vegetable food is to be allowed at all, bread is the only admissible article; and that it should be fermented bread, and somewhat stale. Among animal articles, the flesh of adult animals is preferable to others; it ought to be cooked (in preference) by broiling or roasting, and with as little salt as possible, lest thirst be excited; it should be taken three times a day, at most,—the largest meal being that of dinner; and the last meal must be taken at least two or three hours before bed-time. In the middle walks of society, a greater variety of articles and modes of cooking is advisable; otherwise an animal diet soon becomes irksome; but, in admitting variety in these respects, digestibility is always an important condition. Rollo and some of his imitators have thought, that there is an advantage in the meat being as fat as possible; because it is less digestible than in its ordinary state. But the reason for this preference is far from conclusive; and experience has not confirmed the statement, that much fat tends to restore the healthy constitution of the urine. Others, again, have thought that cheese may form a moderate proportion of the food; on the ground, that in a state of health it

\* Cases of Diabetes Mellitus. By John Rollo, M. D.

is comparatively indigestible, superabundant in azote, and highly productive of urea and lithic acid. Here, too, ulterior experience contradicts early theory. The stomach being apt (in many cases) to be easily disordered, indigestible substances ought not to be preferred; as the urine generally abounds in urea, food producing this principle in abundance is not eligible; and in point of fact cheese, even where well digested, does not appear to possess any advantages over muscular fibre. It ought not, therefore, to constitute a large proportion of the food as some propose; but may be allowed in small quantity for variety's sake, wherever it is found easily digestible. The quantity of the food should be carefully regulated. Exaggerated notions are often entertained of the quantity of food which diabetics consume; and in general, though they have unusual appetite and craving before meals, they will be satisfied with even less than the allowances of a stout man engaged in an active employment. If bread is allowed, sixteen ounces of that article, and twenty ounces of meat (weighed raw), will generally prove sufficient; or it will become so in no long time, if the morbid condition of the urine should begin to yield to treatment.

As thirst is commonly a more urgent symptom than hunger, so it is likewise more difficult to control. The regulation of the drink is, however, one of the most essential articles of treatment. For it must be observed, that extensive indulgence in liquids is (on the one hand) injurious by impairing digestion, or even causing some of the food to pass into the intestines undigested; and (on the other) it has a much worse effect upon the urine, than merely increasing its quantity by simple dilution; since the density is commonly found to be maintained, though the quantity be greatly increased. The patient must, accordingly, be often exhorted to curb the longing for drink as much as possible; and great care should be taken in regulating its quality. It is found that thirst is slaked with a less amount of fluids, when a considerable proportion of the drink consists of such animal infusions as weak beef-tea or mutton-tea; to which may also be added milk in moderation. Except these articles, pure spring water, and probably also such waters as contain calcareous salts in excess, no other ordinary articles of drink are allowable. The water of Bristol Hot-Well, and other calcareous springs, has been found (by Dr. Marsh, Dr. Prout, and others) to be less apt to increase the quantity of urine, than ordinary waters. Beer and other fermented liquors, much as they are longed for by the patient,—also wine and spirits, which he often asks for on account of the sense of languor and oppression that assails him,—tea as being in some measure diuretic, and all acidulous drinks, must be carefully shunned.<sup>a</sup> An important rule is, that he should drink little at a time. Another rule not less essential is, that little liquid should be taken at meals, and the thirst controlled as long after meals as possible; because under these precautions digestion goes on more perfectly, and thirst subsequently is less difficult to appease. Advantage has been found by some in using all the drink warm, because less is required to slake the thirst. While it is desirable that the desire for drink should at all times be controlled as much as may be conveniently accomplished, great and sudden reductions ought never to be attempted; especially when the disease is somewhat advanced.

It is of imperative consequence, that violations of system as to diet be scrupulously avoided. The undue gratification of the thirst, the indulgence in such prohibited articles as beer, spirits, vegetables, pastry or confectioneries, is infallibly followed by an increase in the quantity and density of the urine, when it has been reduced in these respects by previous care in eating and drinking; and one stolen enjoyment is dearly purchased by many days of aggravated thirst and exasperation of every symptom.<sup>b</sup>

<sup>a</sup> When the patient has been in the habit of taking fermented liquors, I [Dr. Prout] have been accustomed (for some years past) to recommend sound porter, in preference to wine or spirits. The quantity must be determined by the circumstances of the patient; but the minimum quantity should be rarely surpassed. With very few exceptions, I have seen more relief from thirst, and more support given by porter in diabetic cases, than by any other means whatever.—*Dr. Prout, on the Nature and Treatment of Stomach and Urinary Diseases. Third Edition; Page 44.*

<sup>b</sup> "Library of Medicine;" Volume 4; Pages 253 to 260.

*Opium.*—There can be no doubt that opium has a great power over the disease; it increases the quantity of lithic acid,—the quantity of urea; and lessens that of the sugar. I have seen this proved repeatedly;—nay, so great is its influence, that a very great quantity will diminish the *urine*, as rapidly as it will diminish the *sugar* in the urine. I once, finding a man dying of the disease, gave him opium so freely, that it induced stupor, and some degree of delirium; and, in the course of sixty hours, the quantity of urine was reduced from *eight* pints to *two*, in the twenty-four hours; and, from being very heavy, it lost the greater part of its morbid specific gravity; and absolutely lost the whole quantity of sugar. Indeed, urea was produced in excess;—the urine contained more urea than it does in health. The man died, a few days afterwards, of phthisis; but the quantity of opium produced the effect I have stated. In general, by giving opium, in increasing doses, we lessen the amount of urine, and likewise the quantity of sugar. Of course, the opium may be increased in this disease, as it may in any other; and one man, who began with half a grain, three times a day, at last took as much as two scruples, three times a day. It never confined his bowels; which it usually does where patients take a large quantity. His urine became natural; when, through a mistake on the part of those who made up the prescription, he had forty grains of blue-pill, which he took three times a day. Thus there was an *absence* of the *opium*, and the *presence* of a strong *purgative*,—a strong *mineral poison*; and instantly the sugar was brought back into the urine, in the original quantity, and the urine also was increased as before. The opium was renewed again; but I never made an impression on the disease afterwards. Whether the benefit would have continued, I do not know.\*

It is said that other narcotics answer as well as opium; but I do not know whether that is the case. However, there was one man who, by repeated bleedings, *appeared* cured; but I did not see him afterwards. I do not know that I ever yet cured a case of this disease; and I dare not say that he was cured by opium, by animal diet, or by any other means. Of course, I am speaking of *saccharine* diabetes; for “*diabetes insipidus*,” may be effectually removed.

*Other Remedies.*—The steam-bath and the hot-bath have been strongly recommended; but I have used them without any material benefit. Iron has also been recommended;—particularly the phosphate; but I employed the sesquioxide, and it appeared useful; though I have never seen it cure the disease. I have not had sufficient experience of the disease in children, to say whether it may or may not be cured. I saw a child, about two years ago, making an excessive quantity of urine; and I think this urine was said to be saccharine; but this state lasted only a few days. Alum, catechu, and astringents, are said to be of service; and it is alleged that they have sometimes cured the disease. But what I would recommend, if the patient's strength would bear it, would be venesection, and a confinement as much as possible to animal diet; and there is no reason why we should not give opium, and at the same time phosphate of iron. These all act in a way that we do not understand; we are not sufficiently acquainted with the disease to say that they will not do good; and if I found a remedy serviceable, I would recommend a patient to use it. It is right always to make a patient wear plenty of clothes; to keep the surface as warm as possible. Warm clothing, and exercise to sweating, have been recommended; but I have known persons perspire profusely in the disease, without any good being done.

### SECTION III.—EXCESS OF UREA IN THE URINE.

There is an affection very similar to diabetes, and sometimes mistaken for it; and that is, where the urea is in excess. I do not know that the disease has been

\* In the “*Lancet*” for December 1, 1832, (No. 483, Page 319,) will be found a case illustrating the efficacy of Muriate of Morphia in this disease.

noticed by any one except Dr. Prout; but I have seen several cases of it; all of which have done well.

*Symptoms.*—There is debility; lowness of spirits; pain in the loins; thirst; an excessive quantity of urine; a diminution and frequently a loss of sexual power; often irritation at the neck of the bladder; and a frequent desire of making water. The urine is pale, and likewise heavy,—perhaps the specific gravity is from 1.025 to 1.030. It is acid; but soon grows alkaliescent. On evaporating the urine, we find no sweet extract; and if we add strong nitric acid to the fluid, we have a precipitation of the urea. This state of the urine is frequently seen where the phosphates are in excess. Equal quantities of nitric and muriatic acid must be added, in order to produce crystals.

*Treatment.*—The remedy for this state (as for diabetes) is opium,<sup>a</sup> and likewise iron.<sup>a</sup> I have seen these cases yield to the exhibition of one or both these remedies. Dr. Prout has cured many cases, which were thought to be diabetes, till he examined the urine, and found no sugar in it. The patient complains of the symptoms I have narrated;<sup>b</sup> and if we find it to be this disease, it may yield to the remedies I have just named. If the patient's health be improved, the disease may cease spontaneously. It is by no means a formidable disease,—like the formation of sugar.<sup>c</sup>

Just as, with respect to the *solids*, we have an excess of development, or an alteration of natural structure,<sup>d</sup> so the same is observed occasionally in the *fluids*. The natural constituents become changed in their proportions; and just as, in one part of the body, we have cartilage, or bone, where it ought not to exist,—so, with regard to the fluids, we find them containing something which ought not to be there; but still something which is natural to the body; or we find them containing something in excess. Again, as, with regard to *structure*, we sometimes have a new structure altogether,—a structure that ought not to be in the body at all;—such as melanosis (if we choose to call that a *structure*), and scrofulous disease, which is a foreign substance;—so occasionally, in the *fluids*, we find things that ought not to be there at all. Of these sugar in the urine is an instance. We have changes in the fluids analogous to *transformations* in the solids;<sup>e</sup> and we have further changes, which are analogous to *new formations*.<sup>f</sup>

#### SECTION IV.—SERUM, CHYLE, AND FAT IN THE URINE.

Before describing that disease in which there is sugar in the urine,—which is a *new formation* altogether, and not found in any part of the body,—I ought, for the sake of uniformity and consistency of plan, to have mentioned some other affections;—those in which there is merely a *transformation*, if I may so term it;—in which we find in the urine things which are natural to the *body*, although they ought not to be present in the urine.

*Serous Urine.*—One of these articles is serum; the presence of which is easily ascertained by the application of heat. It coagulates (as we know albumen does) at 160 degrees; or it will coagulate on adding a small portion of acetic acid, and then prussiate of potass. I spoke of this as occurring sometimes in inflammatory dropsy, sometimes where there is no inflammation to be discovered, and sometimes where there is no disease of the kidney to be ascertained.<sup>g</sup> When serum exists in the urine, the urine may be of its natural quantity, or it may be below it, or it may be in excess. Generally the urine when made is pale; sometimes it is, when first made, a little opaque. I need not say any thing more about this; as I described it so fully when treating of dropsy.<sup>h</sup>

*Chylous Urine.*—Fibrin sometimes exists in the urine;—not as a deposit from the ureters or bladder, but really as the product of the kidneys. At least, it was

<sup>a</sup> See Page 985.

<sup>d</sup> See Page 176.

<sup>e</sup> See Page 161.

<sup>b</sup> See the previous paragraph.

<sup>c</sup> See Page 181.

<sup>h</sup> See Page 159.

<sup>c</sup> See Page 977.

<sup>f</sup> See Page 159.

so in a case which I saw. I have seen only one case, but that I repeatedly examined; and I found it was the fibrin of chyle;—there being fibrin in *chyle*, as well as fibrin in *blood*. The case to which I have just alluded, was very remarkable. The woman was otherwise in very good health; but soon after she passed urine, a coagulation took place; and there was a quantity of something exactly like “blanc mange;”—as much as would fill a tea-cup. Occasionally it coagulated; so that she could not make water. I showed the discharge to Dr. Prout; who examined it, and ascertained that it was chyle. She went on, in this state, for two or three years; and, in the midst of it all, she gave birth to a child;—it seemed to make no difference in that way. I have every reason to believe she is now alive. Dr. Prout has seen six or seven cases since that time. I wished to make some observations upon her; and begged her not to take any food for twenty-four hours;—in order that I might see if it would check the formation. There was this change produced;—the coagulum approached nearer to blood. It had a fine pink colour; and the more she fasted, the more it approached to red;—it was more and more converted into blood. There was no fresh food taken to form fresh chyle; and consequently the chyle became more like blood. Around this coagulum there was a fluid, which was very serous,—contained a good deal of albumen in solution; and, of course, there was urine; but the fluid scarcely smelt of urine, till it was concentrated. One hundred grains of the fluid, on evaporation, gave only half a grain of urea. Nothing was done in this case; but Dr. Prout told me that, by the long-continued exhibition of opium, two or three times a day, he had been successful in curing this disease. The quantity of substance was altogether deceptive to the eye; for, on evaporating this large coagulum and examining it, there was very little solid matter; and therefore the loss to the system was by no means so great as, at first sight, we must have imagined.

*Discharge of Fat.*—Fat has occasionally been found in the urine. When speaking of a discharge of fat from the intestines, I stated that, in some cases mentioned by authors, fat was found in the urine;<sup>a</sup> and in the case of a lady whom I know, but whom I do not attend, the gentleman under whose care she is assures me, that a large quantity of fat is discharged along with the urine.

## CHAPTER III.

### CALCULOUS DISEASES.

#### SECTION I.—URINARY SEDIMENTS.

CONCRETIONS are of a mixed nature. They may consist merely of the natural constituents of the urine; and may therefore be analogous to those diseases of the solids called “transformations;”<sup>b</sup>—in which things naturally found in the body are present. Or they may be new substances,—such as ought not to exist in the body at all;—being analogous to those which are termed “new formations,” or “*non-analogous* changes of structure.”<sup>c</sup> Before entering on the subject of urinary concretions, however, it is necessary to make some general remarks on the nature of urine and its constituents.

*Acidity of healthy Urine.*—Healthy urine, when it is first made, is acid. It will stain litmus-paper; and, if the bladder be not very retentive, and if persons be not very particular (as is sometimes the case with old gentlemen), their dress will be stained;—it becomes red on account of the acid in the urine. Chemists say, in

<sup>a</sup> See Pages 930 and 931.

<sup>c</sup> See Page 189.

<sup>b</sup> See Page 184.

general, that the urine is acid when first made; but Dr. Prout contends that it is not pure uric acid, but lithate of ammonia, that stains litmus-paper red.<sup>a</sup>

*a. Amorphous Sediments.*

*Lithic-acid Deposits.*—But the urine sometimes contains *nitric* acid; and we know that, if nitric acid be added to lithic acid, erythric acid is produced. It is of a very fine scarlet hue. If to this erythric acid pure ammonia be added, a purpurate of ammonia is produced; and if we treat this purpurate with potass, and then again with sulphuric acid, a new acid is formed,—called “purpuric acid;” so that erythric and purpuric acid do not exist naturally in the urine, but are the result of other changes. If nitric acid be formed (by disease) in the urinary secretion, purpuric acid may be formed; and then (as there are soda, potash, and ammonia, in the urine) we may have the purpurates of soda, potash, and ammonia; and if these are added to the lithate of ammonia, then the lithate of ammonia which may exist in the urine, becomes of a fine pink or red colour; and we have a pink or red sediment. Therefore, the pink and red sediments are essentially lithate of ammonia, which is formed in excess,—so as to be insoluble at a common temperature; and they are deposited in the urine because they are in excess, or because the *acid* is in excess;—they are super-lithates. The lithate of ammonia, and the other lithates, are *white* of themselves; but, from the presence of the purpurates, they acquire a *red* or *pink* colour; and if the yellow matter of the urine be absent (as in hectic), then, instead of being *red*, they become *pink*. All this, however, is comparatively unimportant.

In pyrexia, nitric acid appears to be formed in the urine; and the lithates (particularly the lithate of ammonia) are in excess; and, in consequence of the excess of lithic acid, or of lithate of ammonia, and the formation of the purpurates by nitric acid, a copious red sediment is produced; and though it is originally owing to the nitric acid, yet it is a lithate (generally the lithate of ammonia) which has been rendered red by the presence of the purpurates.

*Causes.*—All this may be produced by the sympathy of the kidney with any other organ that is affected. From mere catarrh;—slight inflammation of the mucous membrane of the air-passages, we may have this effect produced. In fever, and in inflammation, the same occurrence takes place. If there be organic disease, especially of the liver, it has a tendency to produce pink sediment;—that is, it causes an absence of the yellow matter; and consequently the sediment is pink. Very trifling things will produce this state, in some people. Anxiety, strong exercise, a little pie-crust or pastry, or the slightest derangement, may cause a red or yellow sediment. Hence Dr. Prout has called this—“the sediment of health;” though it is seen in disease. He means that it occurs from such slight causes, that it is hardly worth while to consider it as an indication of disease. All is not right, but still it will happen every day; and, indeed, by far the most frequently when the person is in a state which we cannot denominate “indisposition.” Generally the redder or the pinker the urine is, the more scanty is its quantity.

*Deposition occurs when the Urine cools.*—The temperature of the urine, when in the body, is sufficient to keep these matters suspended; and therefore it is generally passed clear; and it is not till the fluid is cool, that the sediment appears; and even then, if the person make water a short time afterwards, the heat of the fresh quantity of urine, causes the sediment of the former to be dissolved again; though, of course, a second cooling occurs. For this reason we observe this sediment far more frequently in *cold*, than in *warm* and *hot* weather. In hot weather, though the urine perhaps contains every thing necessary for such a deposition, yet it does not produce it; but in cold weather, if it so happen that the urine is not in excess

<sup>a</sup> “On the Nature and Treatment of Stomach and Urinary Diseases. By William Prout, M.D.” Third Edition. Introduction, Section 8; Pages 74 and 75.

<sup>b</sup> Dr. Prout, on Stomach and Urinary Diseases. Book 1; Chapter 3; Section 3; Subdivision 1. (Third Edition; Page 196.)

(as it so frequently is),—if we are not chilled,—if we are in a warm room,—if we do not diminish the perspiration, the quantity of urine remains the same as before; and then, on making water, in a cold room, we are almost sure to have this sediment; although in summer, in the same circumstances, we should not; for the external heat would then be quite sufficient to keep these ingredients in a state of solution.

*Varieties in the Colour.*—There is great variety in the colour of the sediment. Sometimes it is red; sometimes it is reddish; sometimes it is brown (the colour of a ripe hazel-nut); and so on;—fainter and fainter, till the sediment is nearly white, or perhaps quite so.

*Lithic-Acid Deposit shows Acidity.*—When we see *red* or *pink* sediment, the urine is generally *more* acid than in health; and when it approaches more to *yellow*, it is *less* acid. It shows that there has been less nitric acid; and that less of the purpurates have been formed. A less change, therefore, has been produced on the lithate of ammonia by the purpurates; and therefore we have a fainter colour. This is all very intelligible; but, it is necessary to show it, in order that it may be fully understood. In those states of the body in which there happens to be nitric acid formed in excess, we have the purpurates; and the purpurates, being present and united with lithates, produce a red or a pink colour;—just as it may be. In the case of red or pink sediment, therefore, the urine is acid; but if it so happen that nitric acid is not formed in abundance, then the purpurates are not produced in so much abundance; and therefore they cannot change the colour of the lithates (which is naturally *white*) to a *red* or *pink* hue. Hence, whenever this sediment is red and high-coloured, we generally find the urine very acid; and in proportion as it is paler,—goes through a faint brown and approaches to white,—in that proportion, generally, is the urine less acid. It may even be deficient in the *natural* quantity of acid; and be rather *alkalescent*. The urine, when there is acid, is high-coloured; but when the sediments are pale, and the urine is not acid, then the urine generally is pale also.

*Oxalate of Lime.*—Besides the *nitric* acid, *oxalic* acid has been found in the urine, in the form of a sediment; not a *powdery*, but a *crystallized* one; and is in union with the oxalate of lime. Once only has Dr. Prout seen a powdery sediment;—what he calls “an amorphous uncrystallized sediment of oxalate of lime,” and then it was mixed with ammonia. We shall see, with regard to oxalate of lime, that one calculus consists entirely of it; and the tendency to produce oxalic acid, it is said, has been sometimes traced to eating sorrel; which contains that particular acid. But of that I will speak presently.

*Phosphatic Deposits.*—If the sediments of the urine be absolutely white, then they are not the lithate of ammonia, but the phosphate of lime, the phosphate of magnesia, or the phosphate of ammonia, or more than one of these. In this state of things,—when there is this absolutely white sediment of the phosphates,—the urine is *not* acid. On the other hand it is *alkaline*; or it becomes so very soon after it is passed. It is rare, certainly, for the urine to be quite alkaline at first. Sometimes the urine is all but alkaline; and it is no sooner passed, than it emits a strong smell of ammonia. The best test for alkalies is, not *turmeric*-paper, but *litmus*-paper which has been exposed to acid. Reddened litmus-paper is the most delicate test; for the smallest quantity of alkali brings back the purple hue. When the sediments are white, and depend upon the phosphates, the urine differs, in other particulars, from the urine made when the sediment depends upon the lithate of ammonia. The urine, instead of being high-coloured, is pale,—with a faint greenish hue; and, instead of being scanty,—as is the case with *acid* urine,—it is generally abundant; and, very soon after it is made, it undergoes such a high degree of decomposition, that it becomes very offensive, and smells of ammonia. Still there is one exception to this; and that is, when lithate of soda has been deposited. I have had one case of this description; and, I suppose, others have had many. There was a white sediment in the urine; but it did not depend upon the phosphates; and therefore the quality of the urine was like that which is seen where there is *red* sediment. The lithate of soda, if not coloured by the purpurates, is

perfectly white. It so happened, in this case, that the lithate of soda was deposited pure; but as it was not a phosphate, the urine was not of that quality which occurs when the phosphates are deposited. It was not abundant, but scanty; it was not alkaline soon after it was made, but acid; for it tinged litmus-paper red.

*Diagnosis.*—One set of sediments consists of lithates deposited in abundance; and they are generally tinged with the purpurates.<sup>a</sup> Another set are always white; and they are phosphates.<sup>b</sup> In one set we have *acid* urine,<sup>b</sup> in the other *alkaline*;<sup>b</sup> namely, where there is an alkaline phosphatic disposition. In one set the urine is *scanty*,<sup>b</sup> in the other it is *abundant*;<sup>b</sup> in one it is *high-coloured*,<sup>b</sup> in the other it is *pale*, and frequently of a green hue.<sup>b</sup> If it so happen that the purpurates are not formed, we may have a pure lithate of ammonia; and the deposit will then be *white*;<sup>a</sup> just as if it were a phosphate.<sup>b</sup>

*Cause.*—This state of the urine—where the phosphates are deposited, and where the urine is abundant, and disposed to alkalescency (not staining litmus-paper)—does not show an inflammatory state. The *other* secretion of urine<sup>a</sup> shows an inflammatory condition; but this is connected with an irritable state of the system,—a state of debility.

*Alternation of Lithates and Phosphates.*—However, these very states run into each other. We may have persons passing one description of urine, with one kind of sediment, and then the other, alternately; and we may have persons verging from one to the other;—so that there is no certainty. Persons are in a sort of mixed transition-state; where matters are much confused. Most probably, they begin with acid urine, and the lithic deposits;<sup>a</sup> and yet they are actually passing into the other condition,<sup>b</sup> which is the worst state of the two. The sediments are sometimes seen to be mixed. In the sediment, we have occasionally lithic acid, the lithates, and the phosphates also at the same time;—so that the whole state of the patient may be one of transition. Sometimes these conditions alternate; so that we may be very much puzzled, perhaps, in the treatment of the case.

*Excess of Urea in Phosphatic Urine.*—Where the urine is abundant, pale, green, and alkalescent,<sup>b</sup> and the phosphates are deposited, it is observed also that urea is in great abundance; but Dr. Prout considers that it is imperfectly formed;—that it is the urea which gives rise to the abundance of ammonia.<sup>d</sup> The way in which this operates he conceives to be the following. In these cases the urea is secreted in abundance. Urea, we know, is a compound; and, being badly formed, it undergoes some change, and affords ammonia. As there is not a correspondent quantity of phosphoric acid, this ammonia precipitates the lime; and then, by uniting with the phosphate of magnesia, a triple salt is formed; which salt is called the “ammoniaco-magnesian phosphate.”<sup>d</sup> This is, of course, a phosphatic sediment; and we may easily know this triple sediment, by its white glistening particles. The urine, in these cases, is alkalescent; because there is such an abundance of imperfect urea,—giving rise to so much ammonia. However, though the abundance of ammonia (from the diseased urea) may be the cause of the deposition of this phosphatic sediment, yet the same effect will be produced from a deficiency of acid in the urine. If there be not sufficient phosphoric and sulphuric acid, the lime will be precipitated; and, not only the lime, but likewise the ammonia and magnesia;—so that we have the “ammoniaco-magnesian phosphate.” Sometimes it is said that an excess of lime is the cause of the mischief. That, however, is rare.

Thus the urine may err through an *excess* of acid, of one kind or other (generally the nitric<sup>a</sup>); or from a *deficiency* of the acids.<sup>b</sup>

#### *b. Crystallized Sediments.*

*Lithic Acid.*—The sediments are sometimes mere powders (called “amorphous”<sup>c</sup>); but sometimes the matters deposited are in a crystallized state. In the

<sup>a</sup> See Page 987.

<sup>b</sup> See Page 989.

<sup>d</sup> Dr. Prout, on Stomach and Urinary Diseases. Third Edition. Introduction; Section 8; Page 89.

<sup>c</sup> See Page 988.

latter case they may, in the first place, be red. These red, granular, crystallized sediments (called "crystallized," to distinguish them from powdery ones) are spiculated crystals. We may see them in the urine. There will frequently be red crystals, with numerous spiculæ, at the bottom of the vessel. Some of them, by chance, may be swimming; and some may be sticking at the sides. These are very nearly pure lithic acid. From the great quantity of nitric acid, most probably, the lithic acid is precipitated. Sometimes the lithic acid is absolutely in excess, so that it is not held in solution; and therefore crystals are deposited. But this is not necessarily the case. The *phosphoric* acid will sometimes do this, and sometimes the *sulphuric*; but frequently it is *muratic* acid; and sometimes it is even said to be *carbonic* acid. It must be an acid of little strength, to precipitate the lithic acid; because any *strong* acid will produce decomposition. The urine—when it deposits this spiculated, crystallized, red sediment—is usually very transparent; and of a fine, reddish colour.

*Triple Phosphate.*—If the crystallized sediment be *white*, it is usually the triple phosphate of magnesia and ammonia; and is called the "ammoniaco-magnesian phosphate." The urine, in this case, is just the same as if the sediment had been in powder. It is alkaliescent, abundant, pale, and greenish; and soon becomes ammoniacal, and undergoes decomposition.<sup>a</sup>

*Oxalate of Lime.*—We may have crystals consisting of oxalate of lime;<sup>a</sup> and then the crystals are of a dark *green* colour; and the urine is found to be acid. But this is a very rare occurrence; and one which I have never seen. The *crystallized* deposits are said never to be found together; while the *powdery* concretions (the *amorphous* deposits) sometimes are.

## SECTION II.—URINARY CALCULI.

If it happen that the crystals just described are larger, or that more solid matter is heaped together, we give to them the name of "concretions." It is merely the same thing on a large scale;—perhaps the union of several of these, deposit over deposit; and a great quantity of solid matter. We may be prepared to understand these concretions, from what I have now said respecting sediments;—both *powdery* ("amorphous") and crystalline.

*Lithic Acid.*—In the first place, we have a concretion which is merely *lithic acid*; and is of a brownish-red or fawn colour. Concretions of this kind are sometimes smooth, but sometimes they are tuberculated,—rather rough. On dividing them, we find that they consist of concentric laminæ within. If they are broken, instead of being divided with the saw, the fracture is imperfectly crystallized, and of a deep fawn colour, like the rest. Sometimes they are not in concentric laminæ; but form an amorphous irregular mass, of a pale colour; but when they are pale, they are generally mixed with a little phosphate of lime, or even a little *oxalate*. If we apply heat to this calculus, it becomes white, and burns away; leaving a minute quantity of white-ash, which is generally alkaline. This calculus is quite soluble in potash; and we may precipitate it again by acid. It descends in the form of a white powder. If we add nitric acid as well as apply the heat, it is dissolved; and, on drying it, we have a fine carmine colour, which is erythric acid.<sup>a</sup> I before stated, that when *nitric* acid is added to *lithic* acid, a fine scarlet colour is produced;<sup>a</sup> and therefore if we take such a calculus as this, and add strong nitric acid to it, we obtain a red colour.

*Lithate of Ammonia.*—The calculus just mentioned (lithic acid) is rarely found pure. It is generally mixed with the *lithate of ammonia*; and it is then clay-coloured,—rather paler than the other. It has, however, the same general character. It is sometimes smooth, and sometimes tuberculated; sometimes it has concentric plates, and sometimes it is an amorphous irregular mass; but it is more

<sup>a</sup> See Page 989.

rarely found in the latter state, than the calculus of pure lithic acid. The most common calculus of this description, is not pure lithic acid, nor pure lithate of ammonia, but a mixture of both. If lithate of ammonia exist in a calculus, either in a pure or in a mixed state, it decrepitates by heat; and if we add potash with the heat, ammonia is soon given off. It is soluble in the alkaline carbonates; whereas a calculus of pure lithic acid is not; and therefore we may easily distinguish the one from the other, by chemical means. A calculus consisting of pure lithate of ammonia, occurs generally before puberty. It is small, and rather uncommon. The calculus of lithate of ammonia is not only continually found mixed with lithic acid, but often with oxalate of lime.

*Oxalate of Lime.*—The next calculus which is found in acid urine, is “oxalate of lime.” This, for the most part, is very easily known. It is brown, rough, exceedingly hard, and generally exceedingly rugged. From the irregularity of its surface, it is called “a mulberry-calculus.” Sometimes it is nearly black. On applying heat, a white efflorescence appears upon it. Oxalate of lime no longer remains, but *pure* lime; and this, being alkaline, will stain turmeric-paper. Occasionally this calculus has been found smooth; but in that case it must be of a very small size. Generally it is a most formidable-looking calculus;—such as would make one shudder, when we remember that it is formed in the human bladder. It is known by its ruggedness and dark colour.

*Cystic Oxide.*—There is another calculus which exists with acid urine; and it is called “cystic oxide.” It is so very rare that, perhaps, we may never meet with it; but I will describe it. It is of a yellowish-white colour, and smooth externally. Internally, it is a confused, crystalline, glistening mass. In point of size, it is small. If heat be applied, a peculiar odour is emitted; and it is soluble both in acids and in alkalis.

*Phosphate of Lime.*—We now pass to the consideration of other calculi; which exist with urine generally deficient in *acidity*, and sometimes bordering very closely on *alkalescency*. These are the phosphates; and the first calculus of which I will speak, is that composed of *phosphate of lime*. The colour is of either pale brown, or white. It is very smooth and polished; and has regular laminæ, which are very separable from each other. It is rare and small; and it is thought, by Dr. Prout, not to be a true urinary calculus; but to be formed in the prostate gland.<sup>a</sup> It is not fusible by the heat of a blow-pipe; and, when dissolved, may be again precipitated. Although this calculus is not dissolvable by heat, yet we may dissolve it in muriatic acid.

*Triple Phosphate.*—There is another phosphate which, unfortunately, is very common. It may be known in a moment. It is the “triple phosphate;”—consisting of phosphoric acid, magnesia, and ammonia. It is white; has no laminæ; and is easily pulverized or broken. This calculus consists of the same substance as the white sand I mentioned.<sup>b</sup> It glistens; and consists of a number of minute, white, sparkling crystals. The surface is uneven;—being covered with minute asperities. If we apply heat or potash to this calculus, ammonia escapes; and therefore our chemical knowledge will enable us to say what it is. If we apply intense heat to it, it will at last melt; but this is effected with great difficulty. It is more soluble in acids, than the phosphate of lime; and may be precipitated again, in the form of minute shining crystals.

*Fusible Calculus.*—We have another calculus which is very common; but not quite so common as the last of which I spoke. This is a compound of the last calculus with the last but one;—consisting of phosphate of lime, united with the phosphate of magnesia and ammonia. It passes under the name of “the *fusible* calculus;” because it so easily melts under the blow-pipe. It is exceedingly white and very friable;—breaking under our fingers, like so much chalk. If we rub it on our sleeve, the coat is immediately dirtied,—as it would be by chalk. Generally,

<sup>a</sup> Dr. Prout, on Stomach and Urinary Diseases. Third Edition. Introduction; Section 8; Pages 108 and 111.

<sup>b</sup> See Page 990.

it is not laminated; but if it be separable into laminæ, we generally find between them the triple phosphate,<sup>a</sup> in the form of shining crystals. When it is not laminated, but in a mass like chalk, it sometimes attains a very large size. It is very soluble in the acids;—particularly diluted *muritic* acid. It is a calculus which frequently gives the surgeon a good deal of trouble,—coming to pieces when he applies the forceps. We may easily separate the lime from this calculus. By adding oxalate of ammonia, the lime goes to the bottom; and then, again, the magnesia may be separated by adding pure ammonia.

*Alternating Calculus.*—We do not often have calculi in forms so simple as those that I have now mentioned; but, very frequently indeed, we have what is called “an *alternating* calculus;” that is, a calculus consisting of these various substances in different layers. In by far the greater number of these cases, we shall find that the *inner* substances are those which I first mentioned;—lithic acid,<sup>b</sup> or (more properly speaking) a compound of lithic acid and ammonia,<sup>a</sup> or oxalate of lime;<sup>a</sup> and then, in the outer part, we find the phosphates.<sup>a</sup> The layers of these alternating calculi may be very various; but the nucleus,—the internal portion, generally consists of lithic acid, or oxalate of lime. When a patient has a “mulberry-calculus, nature at last throws the phosphates around it. It becomes white externally, and loses a great portion of its roughness; so that the patient does not suffer so much as before. The external crust generally consists of a “fusible calculus.” Sometimes we have laminæ of all the three ingredients; but still the external crusts generally consist of the phosphates. When calculi are thickened in this way, they are often very large. As to the *chemical* qualities, they depend upon the layer examined. If we inspect the *outer* layer, we find all the characters of the phosphates; and *within* there are all the characters of lithic acid and lithate of ammonia.

*Mixed Calculus.*—We have another compound calculus; in which the materials, instead of being in alternating layers, are all mixed together. A mass of this kind generally consists of lithate of ammonia<sup>a</sup> and the phosphates;<sup>a</sup> and, of course, the colour will vary with the composition. Accordingly as lithic acid predominates, or the phosphates, so will the calculus incline to a *clay*-colour, or to a *white* colour; and the proportions are quite indeterminable. A “*mixed* calculus,” of this description, is generally very hard;—seldom laminated, and seldom large.

*Carbonate of Lime.*—There is another calculus, called “the *carbonate of lime* calculus;” because it consists of pure carbonate of lime. It is very rare, and very friable. It has all the characters of chalk; and effervesces with the acids.

*Xanthic Oxide.*—This calculus is so very rare, that it has been seen only once. It is called “xanthic oxide.” The substance of this calculus is very peculiar. By the addition of nitric acid it becomes yellow.

*Fibrinous Calculus.*—There are some concretions of the bladder, which have turned out to be nothing more than fibrin.

*Prostatic Calculus.*—Besides these *vesical* calculi, we have calculi in the prostate gland. They are found in two situations;—first, in the *natural cavities* of the gland; and then they are of a yellowish brown colour, and more or less round and small. Sometimes, I believe, these come from the kidney. I have passed thousands of these at different times;—about the size of pins’ heads. I have collected some, and shown them to Dr. Prout; who says they came from the prostate. But calculi are sometimes found in an *abscess* of the prostate; and these are much larger and highly polished. They are chiefly phosphate of lime;<sup>a</sup> and Dr. Prout believes<sup>c</sup> that the “phosphate of lime calculus,” found in the bladder, is in reality a *prostatic* calculus.<sup>d</sup>

<sup>d</sup> The following is Dr. Graves’s excellent Table of Calculi (slightly modified):—

I. Animal Calculi.

1. Lithic (or Uric) Acid.

VOL. I.—63

## SECTION III.—CALCULOUS DIATHESSES.

It appears that there are four elementary kinds of calculi, and four distinct calculous dispositions; to which dispositions Dr. Prout gives the name of "diatheses." In the first place, there is the diathesis to form *lithic acid*,<sup>a</sup> its compound (lithate of ammonia<sup>b</sup>), and a mixture of the two.<sup>b</sup> This is the most common calculus we have. Nearly all the calculi taken from children, if they have not been allowed to remain long, consist of lithic acid, or its compounds, or a mixture of the two; and in the majority of calculi taken from people, of whatever age, it forms the nucleus. Then there is a disposition to produce *oxalate of lime*;<sup>c</sup> and that appears to be a distinct diathesis. Then there is a disposition to form *cystic oxide*;<sup>c</sup> but this is very rare. Then there is a disposition to form the various *phosphates* which I have mentioned.<sup>b</sup> This last succeeds to the others. It is usually after the three first diatheses have ceased, that the disposition to form the phosphates comes on.

*Their comparative Frequency.*—So common is the disposition to produce the "*lithic acid calculus*,"<sup>a</sup> that it is said to predominate in rather more than one-third of all the calculi examined. At least two-thirds originate from it in the first instance. Those which are of a deep fawn-colour, are well laminated, and have quite a crystalline fracture, are nearly pure lithic acid; in fact, it is red crystallized gravel. If, with this diathesis, the calculus is of a pale-brown or clay colour, with an earthy fracture, then it is a compound of lithic acid and ammonia;<sup>b</sup> and generally there is a little mixture of the phosphates, and even a little oxalate of lime; and the more there is of the phosphates and the lithate of ammonia, instead of lithic acid, the paler the calculus becomes. The rarest of these calculi is the pure "lithate of ammonia."<sup>b</sup> The "*mulberry-calculus*"<sup>b</sup> is found to *constitute* rather less than one-seventh of all the calculi which are examined; but it is *contained* in about one-fourth of all the calculi that occur. Of two hundred and seventy-four calculi which were examined, only one was found to be of "cystic oxide;"<sup>c</sup> and in three collections out of five, none were found.

The "phosphates"<sup>c</sup> constitute about one-fourth of the calculi; and one-half of this one-fourth are the "*mixed phosphates*;"<sup>c</sup> that is to say, a mixture of the different phosphates. But this estimate of one-fourth is not very accurate; because it has been taken from the *external* appearance of the calculi; whereas, if these had all been sawn through, it is most likely that, *within*, a number of other ingredients would have appeared.

The "*alternating calculi*"<sup>a</sup> (those which consist of a layer of different substances,—the lithate of ammonia, the oxalate of lime, and the phosphates alternately) form a very large proportion. In these alternating calculi, we sometimes see lithic acid and its compounds externally; and perhaps a foreign body for a nucleus. We see, *within*, alternations of lithic acid<sup>a</sup> and its compounds, and a "*mulberry calculus*"<sup>b</sup> *without*;—that is very common. We see alternations of lithic acid *within*, and the phosphates *without*. We see alternations of the lithic acid calculus *within*, then the "*mulberry calculus*," and the phosphates *without*. Again: we see alternations of the "*mulberry calculus*" *within*, and lithic acid and

the phosphates without. When, however, these alternating calculi are found, the phosphates exist externally; and therefore it appears that the disposition to form phosphatic calculi, does not precede the disposition to form lithic acid calculi, or oxalate of lime. It appears that the disposition to form the phosphates, either takes place originally, or follows the disposition to form the oxalate of lime, or lithic acid calculus; but it is not succeeded by any other diathesis. This very interesting and very remarkable fact, was noticed by Sir Gilbert Blane, in 1812; in a paper published in the "Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge."<sup>a</sup> He states<sup>b</sup> that lithic acid is generally the nucleus in calculi; and that the other depositions are merely the result of irritation. I am not aware that this statement of Sir G. Blane's was adopted for some time; but it has now, by very extensive observations, been proved to be correct. Dr. Prout says, that he never met with one patient in whom the phosphatic deposition was decidedly followed by any other.<sup>c</sup> It usually occurs when irritation takes place.

#### a. *Lithic-Acid Diathesis.*

*Depends on the Kidney.*—The disposition to form lithic acid, evidently appears to reside in the *kidney*; for these calculi are seen in that organ. Indeed, there is no reason whatever for believing that this description of calculus is formed in the *bladder*. It appears to be truly a *renal* calculus. If this diathesis be not very intense, there is merely an amorphous sediment;<sup>d</sup>—such as we all have occasionally. Some people frighten themselves about it; but, unless the quantity be very great, there is no occasion for alarm;—especially if the sediment does not appear when the urine is first made. If it be so abundant as to be deposited before the urine cools,<sup>e</sup>—if it come from the bladder in the form of powder, then there may be danger; and if it not only occurs when the urine is first made, and is warm, but takes place constantly, then (I believe) the individual is almost sure at last to have gravel or stone;—that is to say, he will pass concretions; or have a concretion so large, that it will not pass.

*Prognosis.*—With respect to the lithic-acid sediment,<sup>e</sup> there is more danger in proportion as it becomes paler. When it is of a bright *red* colour, there is not much occasion for alarm; but when it is *white*, there is some degree of danger; because it shows a disposition to deposit the phosphates. I do not say that it *always* shows danger; because occasionally, when it is white, it is merely lithate of ammonia; and it is white because it is not tinged with the colouring matter;—in the way I mentioned before.<sup>f</sup> Very frequently, however, the intensity of it arises from the phosphates being deposited; and when that is the case, there is considerable danger.

*Symptoms.*—Some people will pass crystals with very little irritation; but if irritation be produced by the sediment, then there is generally a mixture of amorphous and crystallized sediment;<sup>e</sup> and when the irritation is very great, it is generally because a large quantity is passed in both these forms. In these circumstances, there is generally more or less pain in the kidney; irritation about the neck of the bladder; a frequent desire to make water; and more or less feverishness. The urine is acid and scanty; it has a high specific gravity. Persons complain of these symptoms, from time to time; and then they will discharge a large quantity of red or reddish sediment. The urine is very acid; and we should always test it. This state of things frequently comes on in persons who have a calculus already in the bladder. Sometimes a calculus is formed in the kidney, and may remain there; and give the patient no trouble. A person may have a stone formed in the kidney, without being aware of it; and we may be surprised

<sup>a</sup> Volume 3; Page 338.

<sup>b</sup> At Page 358.

<sup>c</sup> Dr. Prout, on Stomach and Urinary Diseases. Appendix; Observations on Table 2 (Third Edition; Page 481.)

<sup>d</sup> See Page 988.

<sup>e</sup> See Pages 988 and 991.

<sup>f</sup> See Page 990.

to find it there after death. Sometimes it will only cause an aching pain in the loins; and will not shorten life. But occasionally these calculi produce very great mischief. No doubt they continually pass in the form of minute concretions; and the patient is not at all aware of it; and they will lodge in the bladder, and there grow to the size of which they are found. Sometimes they pass from the kidney, after having obtained a size so large as to give great pain, as they pass through the ureter. This pain in the back, on their attempt to leave the kidney, is attended with vomiting, and perhaps with a great degree of feverishness. Inflammation may be set up, or it may not; and then, after a time, all these symptoms cease, perhaps suddenly; and, in a day or two, if the stone be very large, we have signs of a calculus in the bladder.

The infundibula of the kidney are sometimes filled with these calculi. We see them sticking there; and sometimes the kidney will become blocked up with them. The pelvis is sometimes filled with them; the infundibula become greatly distended; and sometimes the ureter is blocked up with them;—so that the pelvis of the kidney is distended into a mere bag. It is said that, in the museum of the College of Surgeons, there is a calculus weighing seven ounces and a half, which was taken from a kidney, and which caused no symptoms during life. This is analogous to what I stated with regard to the gall-bladder; where a large number of stones will sometimes exist, without being productive of any symptoms.\* These lithic-acid calculi are continually found in the kidney; and are of all sizes. It is probable that, in all the instances where they are found in the bladder, they have descended from the kidney.

Lithic-acid calculi (using the term generically) sometimes occur in great numbers. No fewer than two thousand have been voided, by one individual, in the space of two years; and one hundred and twenty have been known to come away in three days. It is the calculus which, of all, gives the least irritation.

*Causes.*—Children and dyspeptic individuals are most subject to that state of body, in which there is a disposition to form these calculi. The disposition appears to be less between puberty and forty years of age, than before. There is certainly sometimes an hereditary tendency to it; for it occurs in members of the same family,—descendants of each other. It is said to have occurred frequently in those who have cutaneous complaints; but cutaneous diseases are so very common, that I do not know whether the examples are sufficiently numerous, to authorize us in supposing that there is any connection between the two. Something appears to depend upon local situation; for some places are remarkable for the abundance of persons with this sort of calculus; but it is not known in what the peculiarity consists. Undoubtedly there is some connection with a gouty disposition. Persons disposed to gout, frequently become the subjects of this sort of calculus, and this kind of deposition in the urine. Excess in eating or drinking, is always mentioned among the causes; and so likewise is indolence.

*Treatment.*—As to the *treatment* of the disposition to form this calculus, and this kind of sediment, it consists in antiphlogistic measures; for this state of body is certainly, for the most part, inflammatory.

*Diet.*—An individual so circumstanced, should take very little animal food;—sometimes, perhaps, none at all. In many cases, the latter restriction may be necessary. At any rate, animal food should be taken in great moderation; and equal moderation is required in eating altogether. In general, it is necessary to abstain from wine, spirits, and strong malt-liquors; though *mild* malt-liquors may be admissible. It is not merely necessary to abstain from Rhenish wine and claret; but from all strong wines, and every thing that is sour. It is necessary to avoid vinegar, sorrel, oranges, and lemons;—in short, every thing that is acid. It is likewise necessary that the patient should be moderate in the exercise he takes; and that he should keep an open state of the bowels.

*Remedial Agents.*—With regard to *medicine*, colchicum is found to be bene-

\* See Page 896.

ficial; together with light preparations of mercury;—mercury in a moderate quantity;—so as not to debilitate the frame; but to keep down, as much as possible, an inflammatory condition. In connection with colchicum and mercury, neutral salts (such as tartrate of potash) will be very proper. Alkalies are advisable here,—particularly magnesia;—both on account of its being an alkali, and from the tendency it has to open the bowels. A saline draught is an excellent mode of giving an alkali; because, although we thus give a neutral salt, yet it contains a vegetable acid, which is always decomposed within; so that we have the benefit of the alkali which was combined with it. For this fact we are indebted to Sir Gilbert Blane.<sup>a</sup> He was the first who pointed out the impropriety of giving saline draughts, where an alkali was not required; and the advantage attendant upon their exhibition when it was. Dr. Prout, and others who are best able to give an opinion upon it, declare that this is the case;<sup>b</sup> and they frequently give a saline draught, for the purpose of administering an alkali. It is judged advisable, in these cases, to take care that the water which the patient drinks be not hard,—does not contain salts of lime; although water, for the most part, is one of the best beverages which people, in these circumstances, can take. I stated<sup>c</sup> that neutral salts should be given from time to time.

Patients, in this condition, sometimes discharge a quantity of powder, like “ful-ler’s-earth.” It is certainly true that, in this state, a vast secretion of lithic acid,<sup>d</sup> or lithate of ammonia,<sup>d</sup> occasionally takes place in the kidney; and then the irritation is altogether relieved. It comes on in fits;—just like the gout. Some have attempted to bring on a secretion of this earth, by artificial means. For this purpose, some give turpentine and opium, in small doses; and some give onions and leeks steeped in gin, wild carrot, and other herbs. Dr. Prout says, that he has seen great benefit produced by these substances.<sup>e</sup> I mentioned, when speaking of diabetes, that opium has undoubtedly the power of increasing the quantity of lithic acid;<sup>f</sup> and therefore it has been employed where a copious discharge of lithic acid was required all at once;—a *liberation*, if I may so say, of the sediment. But a purgative should be given in conjunction with the opium; because, although the latter may do partial good by exciting a discharge of lithic acid, yet it may do harm by confining the bowels;—to which state they are much disposed. In such a case as this, if the patient be very bad indeed,—if he have violent pain in the kidney, great feverishness, pain down the ureter, and about the neck of the bladder,—we must treat it as nephritis and cystitis;—particularly by cupping him on the loins. We must find it serviceable to put him in a hot-bath, to purge him well, and to give him colchicum, alkalies, and opium.

### *b. Oxalate-of-Lime Diathesis.*

*Symptoms.*—In cases where the disposition is to form *oxalate-of-lime*, or “mulberry-calculi,”<sup>a</sup> the urine is likewise acid. A state of the system, similar to that last described,<sup>a</sup> takes place; and a similar mode of treatment is required.<sup>c</sup> The “mulberry calculus,” like the lithic acid, occurs in both sexes; and at all ages up to fifty. It is about fifty that it is most frequently seen; but it is, I believe, never formed after sixty years of age. The “lithic-acid calculus” and its compounds, occur in persons who are very dyspeptic, and who are disposed to be feverish and irritable; but the “mulberry-calculus” is continually produced in persons who have nothing else the matter with them; and, when produced, it may be discharged. The “lithic-acid calculus” and its compounds (as I stated) have been formed to

the amount of two thousand (of all sizes) in one individual;<sup>a</sup> but the "mulberry-calculus" seldom occurs more than once in a patient's life; or if it does return,—that is to say, if another be produced,—it is generally after a very long interval. The urine, in this state of things, is pretty good, and remarkably clear. The *amorphous* sediment of the oxalate-of-lime,<sup>b</sup> is a very rare thing indeed; and as to the *crystallized* sediment of oxalate-of-lime,<sup>c</sup> that is still more rare. A calculus of this description, often acquires an immense size in the bladder; and it does not appear to be produced accidentally. The lithic-acid or the phosphatic calculus,<sup>d</sup> will be produced accidentally, when there is a clot of blood, or a foreign substance has been introduced into the bladder; but this depends upon a peculiar state of the system, which is not understood;—a peculiar diathesis, which appears unconnected with external circumstances. It sometimes *follows* the deposit of a lithic-acid calculus, and is sometimes *succeeds* by it; but nothing is more common than to find it alone. It sometimes happens, that oxalic acid ceases to be formed, and lithic acid is produced in abundance; and then the deposition in the external part of the calculus is lithate of ammonia,<sup>e</sup> instead of oxalate-of-lime. I have myself known several persons discharge a calculus of this kind. They have been perfectly well; but have suddenly been seized with violent pain in the kidney; which has continued some days,—perhaps only for some hours, and sometimes only a few *minutes*. The pain has shot down towards the bladder, and then ceased; and after a few days, in passing their urine, they have been surprised by something making a noise in the *pot-de-chambre*. Sometimes there has been violent irritation; with all the ordinary symptoms of a stone in the bladder. The stone has escaped, and then they have been perfectly well, and have had no return. I know several persons, in whom this happened many years ago; and who, ever since, have been in perfect health.

*Treatment.*—The *treatment* here, as the urine is acid, is exactly the same as for the lithic-acid diathesis;—that is to say, if there be any inflammatory state of the system, we must suppress it by the ordinary antiphlogistic means. If no inflammatory state can be discovered, still we must put the patient on an antiphlogistic plan. Dr. Prout suggests the propriety of changing the *oxalic-acid* diathesis for that of the *lithic-acid*, by exhibiting muriatic acid. It is merely a suggestion; and I do not know that it is founded upon practical experience.

### *c. Cystic-Oxide Diathesis.*

The *cystic-oxide* diathesis is a very peculiar calculus; and the state of the body in which it is formed, is not known. This calculus is generally supposed to originate in the kidney.

*Treatment.*—The *treatment* of the case, would depend upon the circumstance of the urine being *acid* or being *alkaline*. If it be acid, we must treat it in the way I have mentioned;<sup>a</sup> if it be alkaline, then we must treat it as I shall hereafter mention.<sup>e</sup>

*Prognosis unfavourable.*—Dr. Prout thinks that, in this diathesis, the prognosis is unfavourable;<sup>f</sup> for, in most instances, the kidney has been found diseased; and, in others, there has been an inveterate hereditary tendency to disease of the urinary organs. It appears to be a very exclusive diathesis; for it is found with no other deposition in the urine. There is no other calculous matter *within* this, as a nucleus, or *without* it;—except the phosphates, which are the effect of irritation. The calculus is sometimes incrustated with the phosphates; but that is the result of mere irritation,—not of a disposition to disease.

<sup>f</sup> Dr. Prout, on Stomach and Urinary Diseases. Book 1; Chapter 3; Section 1. (Third Edition; Page 239.)

*d. Phosphatic Diathesis.*

*Symptoms.*—We have now to consider a far worse state of the system;—that in which the *phosphates* are deposited;<sup>a</sup> and which has been called “the *phosphatic*” or “the *earthy* diathesis.” Here every thing is the reverse of what I stated to be the case, where the tendency is to lithic acid or oxalate of lime.<sup>b</sup> The urine is not scanty and high-coloured, but copious and pale; and often it is greenish.<sup>c</sup> On looking at the urine, we may tell what is the state of the parts. We may say that the individual has a phosphatic calculus in the bladder, or is depositing phosphatic sediment. The urine is of lower specific gravity, than in the cases I have already considered;<sup>d</sup> and lower than it is naturally. It is in these cases that the urine very soon putrefies. Sometimes we cannot keep it a day before it is quite putrid;—smelling strongly of ammonia.<sup>e</sup> Frequently, at the top of it, we have an iridescent and white pellicle; which consists of the phosphates, with (I presume) a little mucus. The sediment may be either pulverulent (or “amorphous”),<sup>f</sup>—being a mixture of the phosphate of lime and triple phosphate; or it is crystallized;<sup>g</sup> and then we have the triple phosphates only, in white glistening crystals. The two chief calculi found in the bladder, are the “triple phosphate” (the ammoniacomagnesian phosphate),<sup>h</sup> and that with a mixture of the phosphate of lime;<sup>a</sup> and in that case it is white, is not crystallizable, is friable, leaves a white mark on any thing it is rubbed against, and is very fusible.<sup>i</sup>

This phosphatic disposition, and these phosphatic concretions, are very rarely original. They generally occur subsequently to the formation of other calculi; and subsequently, in general, to the lithic-acid or oxalate-of-lime diathesis.<sup>b</sup> The way in which it usually takes place, is this:—the red sediment becomes a fainter red; and, from the phosphates being more and more formed, it becomes paler and paler, till we have a clay-colour; and then, at last, the phosphates only are formed;—the lithic acid and lithate of ammonia being no longer deposited. The urine then becomes more abundant,—does not show such strong signs of acidity; and, at last, there is no acidity whatever. On the contrary, perhaps, it is even alkaliescent; though that is rare when it is first made. Ultimately, however, (as I have already said,) it very soon putrefies;<sup>c</sup> and in that case it is very alkaliescent;—affecting turmeric-paper a short time after it is voided, and depositing spiculæ of the triple phosphates.<sup>b</sup>

The two sediments of the phosphates,—the sparkling glistening crystals,<sup>i</sup> and that in which there are no glistening crystals, but with which the phosphate of lime is mixed,<sup>g</sup>—sometimes alternate. The same individual will, for a day, or a week, or perhaps a fortnight, deposit glistening crystals of the triple phosphates; and then, at other times, those which do not glisten at all; and sometimes the latter alternate with lithic acid; but then the lithic acid is very pale,—verging to the phosphates;—and sometimes, before it gives way to them, there is an alternation of the two. If there be a great deal of crystallized phosphate, then the urine is very alkaliescent. The urea is very copious; and crystals are sometimes formed, before the urine is discharged from the bladder. This deposition usually takes place after the urine is made; but, in bad cases, it will take place before it is voided; and the instant the urine is made, the deposition subsides to the bottom of the vessel.

In the second phosphatic sediment,—that in which there is a mixture of the triple phosphate and the phosphate of lime,<sup>g</sup>—although the symptoms are similar, as well as the state of the urine, yet they are both far worse than in the first state. In this condition of the body there is no inflammatory state. There are no marks of inflammation; but there is a morbid irritability. There is a bad expression of

<sup>a</sup> See Page 992.<sup>c</sup> See Pages 989 and 991.<sup>e</sup> See Page 989.<sup>f</sup> See Page 992. (“Fusible Calculus.”)<sup>h</sup> See Pages 990 and 993.<sup>b</sup> See Pages 995 and 997.<sup>d</sup> See Pages 995, 997, and 998.<sup>f</sup> See Page 991.<sup>g</sup> See Page 990.

countenance;—showing distress,—showing something wrong in the system. The patient is generally sallow and languid; and experiences pain in the loins. There is generally more or less dyspepsia, and some abdominal derangement. Very frequently, there is a want of sexual power and desire; and when a person complains of that, it is always right to examine the urine. In many cases, we shall find diabetes; in many others, an excess of urea; and in others, again, not only an excess of urea, but likewise a deposition of the “triple phosphate.”<sup>a</sup> The urine will vary on different days, and at different times on the same day;—being at times copious, and at others less so.

*Causes.*—Many of these cases have arisen from an injury of the loins; and they arise, too, from the depressing passions,—from any thing that exhausts the vital powers. In some instances, they appear to have arisen from masturbation, or from excessive venery. Any local irritation, whether in the bladder or in the urethra, will produce them; and therefore this diathesis is rarely found in the kidneys. We generally find no marks of disease in the kidney; but usually in the bladder. When a lithic-acid calculus descends to the bladder, it usually produces irritation; and then the phosphates are produced. The bladder is often diseased, from various causes; and frequently it is inflamed;—so that these calculi appear to be far more frequently formed in the *bladder*, than anywhere else. They have been formed from an irritation in the urethra, reaching to the bladder; but generally it is an irritation of the bladder itself that produces them. Urine having this deposition, has continually been seen after an injury to the spine. After these injuries, therefore, and in diseases of the spine independent of mechanical violence, surgeons expect to find such urine; and, on examination, they generally do. Stricture of the urethra will induce this description of urine. It seems not only to act by irritating the *bladder*, but it also affects the *kidneys*;—causing them to give origin to urine imperfectly acidified. Great irritation,—whether it occurs in the bladder or in the urethra,—gives a tendency in the kidneys to produce urine with a deficiency of acid; and if it be deficient of acid, the phosphates are usually deposited in the way I before mentioned;<sup>b</sup>—from the decomposition of the urea, and the production of other things.

*Treatment.*—In this diathesis, we must not keep the patient low, or bleed him. On the contrary, we must give meat, if he will bear it; and even allow malt-liquors. Although, perhaps, wine may (in general) be too irritating, yet acescent wine is good. The tendency is to alkalescency; and, if it do not disagree with the stomach and intestines, wine should be taken. Acids themselves are proper; especially *citric* and *muratic* acid. Mercury acts here as a poison. If we give mercury, in nine cases out of ten we shall find the urine become more alkalescent, the patient's pulse will become irritable, and all the symptoms about the urinary organs will be aggravated. Opium is required freely,—in order to lessen the irritation. The sulphate of quinine, or a decoction of bark, has been exhibited with the greatest advantage; and iron is frequently useful, though occasionally it is too stimulating. These things must be exhibited with regard to individual cases, as well as on general principles. Saline purgatives, of whatever kind, are improper; for as they consist of an alkaline earth and a vegetable acid, and the latter is decomposed in the system, we are actually giving an alkali;<sup>c</sup> which makes things worse. Saline substances produce great irritation;—such as cannot be borne. It is best to give mild aperients (such as “*confectio sennæ*,” and castor-oil), in moderate doses; so as not to irritate, but merely to prevent an accumulation in the intestines. A small quantity of *muratic* acid will be found sufficient;—five drops will produce a specific action on the urine; but ten or twenty may sometimes be required. There is no difficulty in ascertaining whether one particular treatment is proper or not; for the state of the urine will always determine that point. It is always right to employ litmus-paper, stained red; for, in proportion as the urine is alkalescent, it

<sup>a</sup> See Page 992.

<sup>b</sup> See Page 990.

<sup>c</sup> See Page 997.

will restore the original colour; and (as I mentioned before<sup>a</sup>) it constitutes a far more delicate test than turmeric-paper.

*Ascertain the Condition of the Urine.*—It is the state of the urine which determines all the treatment. Whether there are signs of a calculus in the kidney or not,—whether there are signs of a calculus in the *bladder* or not,—whether there are any of the sediments which I have now mentioned<sup>b</sup> or not,—whether the person is going to be lithotomized, or has been already submitted to that operation,—the urine should be carefully examined; for we have to treat the case in all these circumstances. Where a calculus has been removed, we still have to remedy the condition of the system which gave rise to it; because that condition does not cease on the extraction of the stone. We should examine the urine which is passed first in the morning; because that is the least liable to be influenced by accidental circumstances, and therefore the most likely to show the actual state of the system. It should be put away for twenty-four hours;—in order that we may make a perfect examination. In many cases, we may ascertain the point immediately; but the urine should be allowed to remain and cool; and the sediment, if there be any formed, will then be deposited. This kind of treatment is continually required after lithotomy, or the removal of stones in any other way; and, from the want of making a careful distinction,—from the habit of giving alkalies when there is any thing the matter with the urinary organs, infinite mischief is done. It is far better for nothing to be done, than to do something wrong; and mistakes, till very lately, were made every day,—almost every hour, in the treatment of these cases.

#### SECTION IV.—CALCULI IN THE BLADDER.

*Symptoms.*—The formation of calculi is called “lithiasis” (from *λίθος*, a stone). When there is a stone in the bladder, the symptoms produced are usually a particular pain at the end of the penis;—a pain which the patient describes as “a *benumbing* pain,” and which is increased upon exertion. This pain makes the patient pinch the penis as hard as he can; and if he feel a sudden call to make water, he usually puts his hand to the end of the penis; and children are in the habit of pulling the prepuce. There is a frequent desire to make water, and the stream suddenly stops;—the desire to make water, however, being still urgent. Sometimes a change of posture will cause the urine to flow again. Sometimes the urine, instead of suddenly stopping, will come away drop by drop;—the discharge being attended with great pain, and perhaps with blood. There is pain in the bladder itself, especially on motion; and likewise pain and tenesmus on evacuating the intestines. If the calculus be large, or very rough, there is pain in the neck of the bladder, pain and numbness of the testis of the same side, and pain of the inner part of the thigh, along the course of the anterior crural nerve, and sometimes down to the foot;—so that there is actually pain in the sole of the foot. All these symptoms are rendered worse by exercise.

*Diagnosis.*—Pain at the end of the penis, pain increased on motion, and increased whenever the desire to make water comes on, a frequent desire to pass urine, a voiding of it drop by drop, tenesmus, and the presence of blood in the urine,—all these symptoms may occur when there is no stone whatever. In the course of my life I have had every one of these symptoms, two or three times over, from mere inflammation about the neck of the bladder. The sudden stoppage of the stream, is the sign most to be depended upon. Disease of the prostate, and inflammation at the neck of the bladder, will cause many of the other symptoms. Dr. Heberden says that the pain on voiding the urine is felt *after* making water, in the case of *stone in the bladder*; and worse *before* passing it, in the case of *diseased prostate*; and that in the latter case it is not increased on motion.<sup>c</sup> I believe this is a general fact. The obvious reason why the pain is increased on

<sup>a</sup> See Page 989.

<sup>c</sup> “Medical Commentaries;” Chapter 75.

<sup>b</sup> See Pages 995 to 1000.

motion, in the case of a stone in the bladder, is this. The stone is movable, and may therefore come forcibly in contact with different parts of the organ, by motion; whereas the prostate is fixed. However, the prostate is rarely diseased, except in the case of old men. Dr. Heberden says, that even pain and swelling of the testes are sometimes observed in disease of the prostate.<sup>a</sup> But we may always ascertain whether the prostate is diseased, by passing our finger up the rectum, and observing whether it is enlarged; and the certain way of ascertaining whether there is a stone in the bladder, is to sound the patient. In the latter case there is frequently secreted a large quantity of ropy mucus; which may be drawn out to a considerable length, and which subsides to the bottom of the vessel, in the form of a white tenacious mass. Occasionally, a small fragment of a calculus comes away; and when all the symptoms have become violent,—whatever deposition there formerly was in the urine,—whatever was the diathesis before, it now becomes phosphatic.<sup>b</sup> The urine becomes pale and copious; it loses its acidity, and has great alkaliescence; and if there be any deposition at all, it consists of the phosphates. In this state of things, the agony becomes constant; the patient becomes emaciated; and death ensues. The phosphatic diathesis and the sufferings are proportionate to each other.

*Morbid Appearances.*—After death, the bladder is found to be diseased. The mucous membrane becomes diseased; the muscular fibres are enlarged; and perhaps even the kidneys are affected.

*Cessation of the Symptoms.*—This state of things may generally be prevented by the removal of the stone by a surgical operation; and sometimes it fortunately ceases, from a sac being formed in the bladder. The muscular fibres give way, and the inner coat protrudes between them. Not that the muscular fibres *rupture*; but the inner coat gets between the bundle of fibres; and we see externally, on one part of the bladder, a small protuberance;—consisting simply of mucous membrane internally, and peritonæum externally. Sometimes, if the calculus be rough, the symptoms are diminished by the deposition of the phosphates. Although the phosphates are in general produced by irritation, yet they fill up the interstices between the prominences of the calculus, and so render it smoother than it was before; and, in this way, the symptoms are sometimes alleviated.

*Symptoms sometimes Absent.*—But it is to be remembered that, although a stone *may* produce all these symptoms, yet it does not *necessarily* give rise to them. If the calculus consist of lithic acid, it may be small and quite smooth; and then it may give very little trouble. Indeed, such a calculus has been found after death, when its presence was not at all suspected. The health is sometimes very good, in such cases; and if that be the case, and the patient does nothing calculated to injure him, a calculus of that kind may not increase. A calculus may continue in the bladder for many years without any increase;—provided the person does nothing unfavourable;—that is to say, does not commit any excess,—does not increase the feverishness;—provided he adopts a moderate antiphlogistic plan. Dr. Prout knew a case, in which the presence of a stone in the bladder was ascertained by sounding; and, five or six years afterwards (at the time he mentioned it to me), the patient experienced little or no trouble from it; and frequently, for weeks together, the patient forgot that he had a stone in the bladder, or any thing the matter with him. But the case had been well managed; and the patient had been put on a moderate antiphlogistic regimen,—such as I before mentioned.<sup>c</sup> Dr. Prout also mentioned to me, that he knew a case where four renal calculi existed in the bladder five months, without producing any severe symptoms; and then a little irritation occurred at the neck of the bladder, which led to their removal; and yet one of them was nearly an inch in length. These, however, were *lithic-acid* calculi.<sup>d</sup> The *oxalate-of-lime* calculus<sup>e</sup> (if it be of any size) causes extreme suffering, and so also do the *phosphatic* calculi;<sup>f</sup> and for them an operation is indispensable. No regimen will answer the purpose here;—provided things have not gone so far, that a surgeon would not listen to the operation. Of course, the *nature* of the opera-

<sup>a</sup> "Medical Commentaries;" Chapter 75.

<sup>c</sup> See Page 995.

<sup>d</sup> See Page 991.

<sup>b</sup> See Page 999.

<sup>e</sup> See Page 992.

tion must be determined by the surgeon;—whether it is to be the removal of the stone by cutting, or its reduction within the bladder, or dilatation of the urethra, or any other plan.

*Discharge of Calculi from the Urethra.*—In the male, calculi of really considerable size are sometimes discharged; and instruments have been formed to dilate the urethra;—so as to bring them away without any incision; but these are *lithic-acid* calculi. Nature very frequently discharges them herself. This occurrence takes place far more frequently in the *female*, however, than in the *male*; and much larger calculi have been brought away, both by nature and by artificial dilatation. One which weighed as much as twelve ounces has been discharged by a female. These are very extreme cases. On account of the shortness of the urethra, it is very common for females to pass calculi, by an effort of nature; and it does not appear that females are, by any means, so subject to the complaint as males.

*Vesical Irritation favours the Deposition of Phosphates.*—When the suffering has been very great, and an operation has at last been performed, it is generally found that the calculus is, externally, of a phosphatic kind; but an entire phosphatic calculus is rarely seen. In this state of things (when the phosphatic diathesis exists) the kidney is at first affected only functionally. From irritation of the urinary organs, it secretes morbid urine,—urine which has no excess of urea; together with a tendency to a phosphatic deposition; but, at last, actual structural disease of the kidney takes place. If the kidney could be preserved in a state of functional health,—if it could be made to secrete proper urine, it is probable that, although a stone existed in the bladder, it would not increase, even around an accidental nucleus. But the accidental nucleus produces irritation; that irritation is communicated to the kidney; the kidney secretes morbid urine; from this morbid urine deposition takes place; and so the calculus increases. The moment the urine becomes unhealthy, then a deposit takes place; and the mischief goes on increasing. Frequently, at its origin, the disease does not depend upon any external circumstance; but there is a real disposition to these morbid deposits; which disposition gives rise to them, and they go on increasing, till a calculus is formed. But if, by chance, any thing—such as a piece of bougie or a drop of blood—gets into the bladder,—so as to form a nucleus, this, by inducing irritation, will cause a calculus to form round it. If, by art, we could keep the urine healthy, it is supposed that a calculus would not be formed;—that the nucleus would not serve for any thing to collect around.

*Calculi do not increase regularly.*—It does not appear that a calculus goes on increasing regularly. The urine is not always equally morbid; the irritation is not always equally felt; and external circumstances are not always equally unfavourable. The patient neglects himself, from time to time; or some unfortunate occurrence takes place. Sometimes a calculus has been known to increase very much, and the state of the urine to become more and more morbid; and then, again, the process has been exceedingly slow. There is another reason to make us suppose, that the deposition is not constant. Many calculi have a laminated structure; and between the laminæ they appear to have suffered some diminution. There is a space there; and they frequently look as if they were worn by water moving around them. The occurrence of separate laminæ, indeed, is considered to prove their irregular deposition.

*Age most favourable for Lithotomy.*—It is not only where there is great suffering, or where the urine has become phosphatic, that an operation is proper, provided the case is not too far gone; but if the patient be below puberty,—even although the sediment is not phosphatic; but is red, and consists of lithic-acid and lithate of ammonia,—then it is considered that the calculus should be removed. If the individual be below puberty, there are many chances to one of the calculus increasing, and giving further trouble; and, though the patient may not be suffering much, it is generally best to extract it.

*Mortality from Lithotomy.*—Lithotomy is considered to be less dangerous in children, than in adults. It was found at Norwich to be four times less so. Gene-

rally speaking, the ratio of mortality, from lithotomy, is about one in seven and three-quarters; but in Norwich it is said to be less than anywhere else; so that, for forty years, Dr. Marcet found that the average of mortality there was but one in eleven and three-eighths:—before puberty one in eighteen; and after that period one in four and three-quarters. Nearly one-half of the cases of stone in the bladder, are found to occur before puberty; and then there is an increased number again after forty; and but one female was affected with stone in the bladder, for twenty-three males. Some ascribe this to the quiet habits of females,—to the circumstance of their not being subject to laborious exercise; and others ascribe it to the shortness of the urethra. The latter circumstance must have great influence; but, in all probability, there is less disposition in them to the disease.

These are the only considerations for the *medical* practitioner. With the performance of the operation, I have nothing to do. All that we have to give an opinion on, is the condition of the urine;—taking into consideration, when contemplating an operation, the suffering and the age of the patient.

## CHAPTER IV.

### DISEASES OF THE BLADDER.

#### SECTION I.—CYSTITIS.

*Symptoms.*—The urinary bladder is, of course, subject to inflammation; and this disease is called “cystitis.”<sup>a</sup> The symptoms are a burning and throbbing pain in the hypogastrium; tenderness on pressure; a very frequent desire to make water; and a most horrid pain at the neck of the bladder, while the urine is passing;—so that the patient, perhaps, can only void it on his knees. The urine is made in a very small quantity, perhaps every ten minutes; and it is often high coloured,—perhaps bloody. There is also tenesmus.

*Causes.*—This affection is induced by turpentine, cantharides, and other things which peculiarly irritate the urinary organs; but more particularly by gonorrhœa. The inflammation of the urethra spreads inwards;—producing inflammation of the bladder.

*Treatment.*—The treatment is simple, but requires to be put into practice vigorously.

#### SECTION II.—CYSTORRHŒA.

*Symptoms.*—The bladder is subject to *chronic* inflammation; and it is still more subject to an affection of the mucous surface; in which affection there is a great discharge of ropy mucus,—such as occurs when a calculus exists in the organ, and causes great suffering. There is not only this quantity of ropy mucus secreted; but the mucous membrane itself becomes hypertrophied. As much as several pints of this ropy mucus have been known to be discharged in a day; but it is very common indeed for a pint to be discharged. It subsides to the bottom of the vessel, and is quite white. It sometimes blocks up the urethra; so that a little difficulty is experienced, from time to time, in making water; and at last it is really purulent. This affection is called “cystorrhœa.”<sup>b</sup>

<sup>a</sup> From “cystis,” the bladder (from κυστις, a bag); and “itis,” inflammation.

<sup>b</sup> From κυστις, the bladder; and ῥέω, to flow.

*Morbid Appearances.*—After death, if the disease prove fatal, there is frequently a thickening of the mucous membrane to a great amount. The muscular fibres are seen distinctly; and, in some parts of the bladder, are very much developed. It would seem, indeed, that those muscular fibres described by Sir Charles Bell, and which run from the extremities of the ureters, become hypertrophied;—so that, at the orifice of the bladder, there is a triangle; the sides of which run from the mouth of one ureter to that of the other, and from both to the mouth of the bladder. We sometimes may pass our finger down half an inch;—so great is the development.

*Treatment.*—The treatment of a case of this kind must be antiphlogistic;—so far as the patient's strength will allow. The frequent application of leeches is proper; and if there be no excessive irritation, but more discharge than any thing else, turpentine in small quantities has been occasionally used with advantage; and so has “uva ursi.” We may put an ounce of the latter to a pint and a half of water, and boil it down to a pint. Cubebs, likewise, have been occasionally serviceable. These cases, however, taken altogether, are very bad; and, in a large number of instances, a stone exists in the bladder; or there is a stricture, which gives rise to this irritation; as well as to hypertrophy, or disease of the prostate. If the urine be alkaliescent (deficient of acidity), it may be well to give acids and narcotics, in order to lessen the irritation; and, for this purpose, we may give conium, opium, and hyoscyamus. But when the mucous membrane becomes hypertrophied, and there is secretion to such an amount as this, we can do little more than afford temporary relief.

### SECTION III.—STRUCTURAL DISEASES OF THE BLADDER.

*Hypertrophy.*—So greatly disposed to hypertrophy are the muscles of the bladder, that no other muscles of the body (it is said) are so increased by exercise;—that is to say, if any difficulty exist in the passage of the urine, or there be any irritation about this part,—so as to make the bladder contract frequently, no other muscles grow to the same amount. Indeed, in some cases, the inner part of the bladder looks like the inner part of the heart. The muscular fibres and the mucous membrane are so developed, that, at first sight, we might think it was the right ventricle of the heart. The mucous membrane is often softened, both when it is hypertrophied, and when it is not. Sometimes the villi and the follicles are so apparent, that we perceive them instantly; though naturally they are so minute, that we cannot see them. The cellular membrane is frequently hypertrophied, so that the bladder will become hard; and if a sound be passed into it, the hardness is discovered. The mucous membrane is sometimes enlarged;—so that it presents the appearance of a polypus.

*Fungous Excrescences.*—Sometimes fungous excrescences, of a cancerous or encephaloid nature, take place. I formerly mentioned a case of this kind, where encephaloid deposit gave rise to hæmorrhage, which destroyed the patient.<sup>a</sup>

*Scirrhus Tumours.*—Scirrhus tumours are found in the bladder. They are sometimes original; and sometimes connected with disease of other parts;—with a diseased rectum, or a diseased uterus.

*Cysts.*—A cyst has sometimes been found in the organ. It is almost always connected with its internal surface; and, in that case, is most probably a mere sacculus.<sup>b</sup> A sacculus, however, may be formed originally; and it may become so very large, as to be the same size as the bladder itself. The bladder has sometimes been divided into two chambers, by adhesions extending across.

<sup>a</sup> See Page 204.

<sup>b</sup> The diminutive of “saccus,” a bag.

## SECTION IV.—PARALYSIS OF THE BLADDER.

*Symptoms.*—The bladder is frequently the subject of palsy. When a person labours under paraplegia (a loss of power of the lower extremities),<sup>a</sup> he is generally unable to retain his urine. At first he is unable to make water; so that it continually requires to be drawn off. This we see in paraplegia from accident. After a time, however, the “*detrusor urinæ*” muscle loses its power, and then the sphincter also becomes paralyzed; so that the patient cannot *retain* his urine.<sup>b</sup>

*Causes.*—These parts are much disposed to become diseased in old men;—just as the uterus and the ovaria are disposed to fall into disease in old women. When the prostate and the parts of generation have done their duty, they fall into a diseased condition;—just as similar parts do in women. The bladder suffers with the rest; so that old men are frequently unable to sit like young ones, and will be obliged from time to time to go out of the room. Sometimes this will occur from accidental circumstances. I have known paralysis of the bladder occur from an opiate injection. This is worth knowing. From having a suppository, or an injection of opium, the bladder has become paralyzed; so that it has been necessary to draw the water off; and this has occasioned much alarm. On a repetition of the injection, the bladder has become so torpid, that actually retention of urine has occurred. Sometimes it is produced by a torpid state of the system,—where the head is oppressed. It is a thing which frequently occurs in fever; and sometimes, without any obvious reason, the bladder loses its power;—just as any other part of the body may do.

*Treatment.*—If there be no disease of the spine, no organic disease of the bladder, no inflammation,—nothing more than the simple paralysis, without our being able to trace it to any thing more than torpidity,—then cantharides is one of the best remedies. So perhaps, is electricity; and any thing else that is stimulating.

*Stillicidium Urinæ.*—The bladder may be in this state while the urine is dripping away; for when the organ is distended to a certain amount, the urine will pass (*guttatim*) involuntarily. This is called “*stillicidium urinæ*.”<sup>c</sup> The patient will tell us that he cannot hold his water; while, in fact, the bladder is full, and can hold no more. It is therefore necessary, in these cases, to ascertain the condition of the bladder. Very frequently it happens, that this form of paralysis takes place temporarily. If a person do not make water in proper time, he loses the power of voiding his urine, and distension is no longer felt. The muscles have no longer power to empty the bladder, and it remains greatly distended; although the urine is constantly coming away. When we are told, therefore, that a person cannot hold his water, we have to ascertain whether he is not holding too much, and cannot hold any more.

## SECTION V.—DISEASE OF THE PROSTATE.

*Symptoms.*—With regard to disease of the prostate itself, we may be continually consulted upon it; as it occurs so frequently in old men. From the pressure, there is frequently a great difficulty in making water; and sometimes it acquires so very large a size, that there is difficulty even in going to stool. There is pain there; and the abdomen, at last, falls into a state of disease; and death is frequently the consequence.

*Morbid Appearances.*—After death, we shall find the prostate full of large cells. It is very much hardened; and perhaps it has acquired an immense size. This may be ascertained during life, by the introduction of the finger into the rectum. Calculi frequently come from the prostate; and they are sometimes found, in very large quantity, in the cells of that gland. Occasionally they will grate against a sound, when it is passed on towards the bladder. They are generally small,—

<sup>a</sup> See Page 672.

<sup>b</sup> See Page 974.

<sup>c</sup> “*Stillicidium*” is derived from “*stilla*,” a drop; and “*cado*,” to fall.

sometimes exceedingly so; and are always, I believe, found to consist of phosphate of lime.<sup>a</sup>

*Treatment.*—With regard to the *treatment* of disease of the prostate, we have chiefly to resort to surgery;—drawing the water off regularly. On account of the great pain, however, it is sometimes necessary to employ narcotics; and I think it would be worth while, in such cases, to give iodine a fair trial;—to rub in iodine and hydriodate of potassa externally, and to give it internally. I have not had many opportunities of treating such cases, because they generally fall to the surgeon; but I have treated them occasionally; and temporary benefit has ensued. I have had two or three patients, in whom there appeared to be a temporary alleviation of the complaint; and if any thing would afford temporary relief, it would be iodine. I do not know whether it would *cure* a case of this description; but I should expect to do more good by it than by any other remedy.

<sup>a</sup> See Page 993.

## BOOK VII.

### DISEASES OF THE FIBROUS TISSUES.

---

#### CHAPTER I.

##### GOUT.

I HAVE now finished the consideration of diseases of the urinary organs;—so far as it is incumbent on me to treat of them. I will now speak of an affection, which is very much connected with disease of the urine; although it is another complaint. I refer to *gout*. When persons have the gout, I am never surprised if they have stone;—gout and stone so frequently go together; though gout is a disease which, in the first instance, affects the joints.

*Etymology and Synonymes.*—It is called “the *gout*” from the Latin word “*gutta*,” or the French word “*goutte*,”—which, in its turn, comes from the Latin word “*gutta*,”—*a drop*. It is so called because it was supposed to arise from a deposition of *drops* from some morbid fluid in the joints. In Latin, it is now generally called “*arthritis*,”—“inflammation of the joints.”<sup>a</sup> In the classics, it is spoken of under the head of “*podagra*,” when it affects the *feet*;<sup>b</sup> “*chiragra*,” when it affects the *hands*;<sup>c</sup> and “*gonagra*,” when it affects the *knees*;<sup>d</sup> but all these “*agra*” are comprehended in the term “*arthritis*.” Although this term means “inflammation of a joint” from *any* cause, yet it is now appropriated solely to *gout*.

*Mode of Invasion.*—When this affection makes its first attack, it generally begins at two or three o’clock in the morning;—just at the time that a fit of asthma commences; as, indeed, do some other diseases. Usually it first attacks the ball of the great toe. The patient wakes in the most excruciating pain. He then becomes feverish; and continues in this state till the next midnight; when the pain remits. The following morning, he finds his toe swollen and reddish; and he has exacerbations of the pain for several days and nights. The disease then frequently declines; the patient perspires freely. The cuticle of the part attacked, desquamates; there is violent itching for some days; and then there is an end of the business.

*Peculiarity of the Pain.*—The pain, in gout, is not only very severe, but is also of a very peculiar kind. Sydenham, in writing of his own sufferings, compares them to the gnawing of a dog; and patients who have suffered from it extremely, say they can distinguish between the pain of gout and that of rheumatism.

*Progress.*—After a time, sooner or later, the same thing occurs again. Perhaps

<sup>a</sup> From *αρθρον*, *a joint*; and “*itis*,” *inflammation*.

<sup>b</sup> From *πους*—*podos*, *the foot*; and *αγχα*, *a seizure*.

<sup>c</sup> From *χερς*, *the hand*; and *αγχα*, *a seizure*.

<sup>d</sup> From *γενυ*, *the knee*; and *αγχα*, *a seizure*.

the disease attacks the balls of *both* great toes; perhaps it flies from one to the other; and perhaps it affects the hands, the knees, or the wrists. So also it will shift its place, during the same attack;—running from one knee to the other, from one wrist to the other, from one ankle to the other, from the hand to the feet, and *vice versâ*. The more frequently it comes, the less probability is there of its being confined to the fingers or toes; and the more likely is it to spread to the ankle, to the wrist, or even to the elbow and other joints: perhaps the shoulder becomes affected. But it begins at first in the smaller joints, and affects them to the last;—going to the others only occasionally. Generally the intervals between the attacks grow shorter;—the patient has fits more and more frequently; and they often last longer. The joints, at last, may become stiff; and deposits will take place under the skin; so that the joints of the fingers and toes become enlarged, swollen, and harder than is natural. Occasionally a solid deposition of a white substance takes place, and sometimes it is fluid;—so that if we prick the part (which is soft) with a needle, we squeeze out a quantity of matter, like soft mortar. Not unfrequently there is a nephritic attack;<sup>a</sup> with a deposition of lithic acid, or some compound of it.<sup>b</sup> Occasionally these things take place with the gout; occasionally they take place only during the intervals; but a deposition in the urine, and a fit of the gout,—where there is a deposition in the joints,—are frequently very closely connected.<sup>c</sup>

*Improves the General Health.*—After the attack, people are generally better than they were before. They find it does them good; and therefore they are not at all sorry that they have had the disease. Many persons long for a fit of the gout, when they have not had it before. They say that gout is in the family; and that if they had an attack, they should do well. Those who *have* had it, if any thing be the matter with them, are satisfied that they should be a great deal better, if they had another attack, and many people try to bring it on.

*Premonitory Symptoms.*—Before the attack, there is frequently indisposition of some sort;—the symptoms that I mentioned under the head of “disorder of the digestive organs.”<sup>d</sup> There may be languor, or lowness of spirits, or pain of the head, or wandering pains (*gouty pains*) coming and going in the larger or smaller joints. Sometimes there are palpitation and giddiness;—functional diseases, in short, in almost every part of the body.

*Varieties of Gout.*—If these symptoms exist for some time,—so that the patient really feels himself diseased, the disease is called “*atonic gout*,”—gout without strength,<sup>e</sup>—gout where there is not sufficient strength to bring it out. A *gouty* disposition exists; but there is not activity enough in the system to bring it forward. Sometimes, when the gout has come on in a very satisfactory manner, it will suddenly cease. It will not retire to another joint, but will suddenly cease altogether; and the patient will have some internal affection;—perhaps apoplexy, perhaps violent vomiting, perhaps gastrodynia, or perhaps violent colic. It will be some severe internal disorder; and it is then called “*retrocedent*<sup>f</sup> gout.” Sometimes the affection within is of an inflammatory nature; and then it is called “*misplaced gout*,” but it is no matter whether we call it “*retrocedent*” or “*misplaced*,” for inflammation is very often ascribed, by old authors, to some nervous affection, or to something else. We have only to consider that, if the gout does not come out satisfactorily, it is “*atonic gout*,” whereas, if it suddenly cease, and an internal part is affected in a violent degree, it is “*retrocedent gout*” or “*misplaced gout*,” according to the affection that is going on.

*Symptoms relieved by Gout.*—Some persons have had very extraordinary symptoms relieved by gout. I knew a gentleman who had had pain of the sto-

<sup>b</sup> See Pages 991 and 992.

<sup>c</sup> Lithic acid, developed principally during the mal-assimilation of the albuminous textures, may be considered as the characteristic feature in gout.—*Dr. Prout, on Stomach and Urinary Diseases. Book 1; Chapter 3; Section 3; Subdivision 4. (Third Edition; Page 210.)*

<sup>d</sup> See Page 944.

<sup>e</sup> From *a* (privative); and *τονος*, strength.

<sup>f</sup> From “*retrocedo*,” to go back.

mach (gastrodynia) for many years. I know not *how* many years it was; for he did not attend to it much; but at last a fit of the gout came on; and he has never experienced the pain since. Palpitation, after existing for a long time, has frequently ceased upon the occurrence of a fit of the gout. Strangury, cystorrhœa, piles, and almost every disease that can be mentioned, have ceased on the appearance of gout. Sometimes they alternate with gout; and if such affections be very violent indeed, then they may be called "misplaced gout;" for they have come on when gout should have appeared.

*Predisposing Causes.*—The disease, at first, most frequently commences about the end of January, or the beginning of February. There is no universal rule; but it occurs more frequently then, than at any other time. It occurs in males, much more frequently than in females;—just as is the case with regard to "stone."<sup>a</sup> It is also said to occur in *robust* males, far more frequently than in *weak* ones. It never has been known in eunuchs;—at least, so it is said. If such be the case, gouty old gentlemen have an easy remedy. It is also a disease that is very hereditary. This is one of the great hereditary affections. If it occur in females, it is generally in *masculine* females;—those who have a little touch of the male in them;—robust, hearty-looking women. I do not say this is the case *universally*; because I have seen the reverse myself. It occurs particularly in men who have circular chests, short necks, and what are called "*thick* heads;"—not in those who have large foreheads; but in those who have bulky heads altogether, and who are of full habit. It occurs chiefly in those who eat a great quantity of flesh-meat, and drink a good quantity of wine. Among those who are predisposed to it, it seldom occurs till after thirty-five years of age. I have seen it in persons below puberty; and it is said to have occurred in infants; but, more frequently than not, it takes place in those who are above thirty-five, who indulge at the table, and who are of a plethoric habit. Such are the predisposing causes.

I mentioned that, for the most part, males suffer from it more than females;<sup>b</sup> and that where it does occur in the latter, they are very robust. The males who experience it are chiefly those who are thick, stout, and of a sanguineous temperament; but occasionally it occurs in persons who are extremely thin, spare, and emaciated. Although the disease, in a great number of cases, is connected with a certain development or form of body, yet, in many instances, it certainly does arise independently of any external appearances whatever. Sometimes very delicate women are subject to it;—persons who appear the least likely to suffer from it. In those cases in which the external appearances are not such as would lead us to suppose that the patient would have it, there is usually a strong hereditary predisposition; and where this predisposition exists, we shall have the disease,—whether it is hereditary or not. It will also occur in the most temperate individuals;—in persons whose habits are such, and *have been* such, as to make it very unlikely that they should have an attack of gout. The disposition to the disease may be exceedingly strong; and persons may become the victims of it, independently of the external appearance of the body; and independently of any of those excesses which so frequently produce it.

*Increased Frequency of the Paroxysms.*—I stated, with regard to the progress of the disease, that it generally begins in one great toe;<sup>c</sup> that, on the second attack, it perhaps occurs in both;<sup>d</sup> and that so it spreads to the other joints;<sup>d</sup> till, at last, after several paroxysms, many joints will be affected.<sup>d</sup> And not only does the disease become more extensive, but it also becomes more frequent; so that persons at first, perhaps, have a paroxysm every year or two; and then every year; then two or three paroxysms in a year; and at last they are scarcely ever without it;—they have it on the least exciting cause. I should have mentioned, also, that some persons never have above two or three fits in the course of their life. I know an instance of an individual who, when about thirty-five years of age, had an attack of regular gout; and, although he is now upwards of seventy, he has never had an

<sup>a</sup> See Page 1003.

<sup>c</sup> See Page 1008.

<sup>b</sup> See the Previous Paragraph.

<sup>d</sup> See Page 1009.

attack since; though he has taken no particular care to avoid it. These are exceptions to general rules.

*Gout formerly desired.*—I mentioned that many symptoms will cease, when an attack of gout appears;—so that it is a very common thing for persons who have suffered in various ways, to suffer no longer after they have had a fit of the gout.<sup>a</sup> This fact made so great an impression on the public, at one time, that gout was longed after as a great blessing; and people, with all sorts of complaints, would eat and drink, take a large quantity of wine, and do all they could to have a fit of the gout. As it is a disease which attacks the rich more than the poor, it was altogether a fashionable complaint. It was thought a creditable disease; and, at one time, every body longed for it, or declared that they had had it. This whim is strongly argued against in Dr. Heberden's "Commentaries;"<sup>b</sup> which it will be worth while to read;—not only on account of the elegant Latin, but for the excellent description which he gives of the disease; although, for the most part, he adopted poor and inert treatment.

*Influence of Ardent Spirits.*—The disease is particularly favoured by indulgence in wine. All fermented liquors do not appear to give the same tendency to it; and as to spirits, I am inclined to believe that, so far from disposing persons to the disease, they have a tendency to prevent it. At least, I hardly know an instance in which a person who has committed a great excess in spirits, labours under the disease; although wine-drinkers have it every day. It is a very rare complaint among the poor. Now and then we see it among them, because there is a peculiar predisposition to it in some persons; and sometimes it is hereditary, and will occur in spite of the absence of all the ordinary causes; but, for the most part, we do not meet with it in the lower walks of life. I have seen persons who, from their make of body, and from the occurrence of the disease in their progenitors,—many members of the family having had it,—were the most likely persons in the world to experience it; but who, from indulging in spirits to a disgraceful excess (and excess of that kind is *always* disgraceful) have not suffered from gout; although, beforehand, one would have said that they were most likely to have it by the time they were forty or fifty.

*Paroxysms induced by slight Causes.*—When a person is liable to gout, a paroxysm may be induced by the very slightest cause. If he indulge in eating and drinking too much, on any particular occasion, a fit of the gout is very likely to be the consequence. It will occasionally ensue from mental anxiety. Exposure to cold—which, in another individual, would induce an inflammatory complaint—will, in those predisposed to gout, produce a paroxysm. Even accidents—such as a sprain of a joint—will become local causes; and the patient will have an attack of gout, in that particular part.

*Induces internal Affections.*—When persons have the disease for a length of time, it is very common for internal organs to become seriously diseased. It is very usual to see persons who have been the victims of gout become asthmatic, or have disease of the kidneys, or have organic diseases of the stomach and intestines, or have chronic bronchitis. Very frequently, disease of the heart supervenes, and disease of the head occurs;—so that they die apoplectic. The gout, at last, is not confined to the extremities; nor are the internal symptoms merely functional; but the organs in the three great cavities of the body become diseased.

*Prognosis.*—The prognosis must depend on the original disposition, on the part of the patient, to the disease; and also, in a great measure, upon the resolution which he has to follow up our advice. A great number of persons who have the gout, are very disobedient in this particular.

*Treatment: Regimen.*—With respect to the *cure* of the gout, in general it is necessary that the patient should be very abstemious;—that he should live as low as he can to be in good health; and take as much exercise as he can bear;—only taking care that his health is not impaired by its violence. It is impossible to lay

<sup>a</sup> See Page 1009.

<sup>b</sup> Chapter 9.

down any specific rule; and to say that a man, disposed to gout, should not drink wine,—should not drink beer,—should not eat meat, would be wrong. There are some gouty patients who would be better, if they left off fermented liquors; others would be better if they went farther, and ate no meat, but confined themselves to vegetable diet and milk. There are other cases, again, where this would be absurd;—the patient could not live without meat; and there are other cases where it is necessary to allow a certain quantity of wine. The stomach of many persons labouring under gout is so weak, that they cannot digest their food without a certain allowance of wine; but, generally speaking, the diet I have recommended, and as much pleasant exercise as possible without weakening the patient is advisable. No doubt, however, there should be extreme temperance: the patient should not take more wine, or eat more meat, than is necessary. Many persons will thus get rid of the gout altogether, with the most perfect ease; while others, who will not get rid of it (and these may be by far the larger number), will have it very much mitigated. It is necessary that they should be particular in their food;—that if they eat any food, they should take that which is the most digestible; such as fresh mutton, or fresh beef; without any sauce, or elaborate preparation on the part of the cook. They should take simple Sherry or Madeira, and not mixed wines. Above all, they should not take acescent wines, such as Champagne; and perhaps they had better take brandy-and-water. Many persons, from taking Rhenish wines, or Claret, or Champagne, have a fit of the gout directly. In general, Sherry agrees best; and therefore we should recommend it;—unless the person knows, from his own experience, that some other wine, or a small quantity of brandy mixed with water, is better for his constitution. I am supposing that the stomach of the patient requires such a plan to be adopted.

*Friction.*—Friction is exceedingly useful, when exercise cannot be adopted. It would be well for many persons who are lame in the feet, to be rubbed down, once or twice a day, like a horse. They would also find it a very great luxury.

*Colchicum and Antiphlogistics.*—In a regular fit of gout, the best medicine that can be given, is colchicum. We should exhibit the wine,<sup>a</sup> in half-drachm doses, every six hours; and it should be mixed with some other purgative; because we want its action to be speedy. The sulphate of magnesia makes a good combination with it. We may produce purging in twenty-four hours, or sooner; and when that takes place, the patient is generally relieved at once. Any good, active purgative will have a beneficial effect; but colchicum appears to be more efficacious than any other. Unless it purges, however, it will seldom have any influence. Now and then, the symptoms will all cease after two or three doses; but, in the greater number of instances, so desirable a result does not occur till purging takes place. It is better to quicken the purgative effect, in order to prevent it from griping; and the sulphate of magnesia will excite its action so much the sooner. Venesection may be advisable in young persons; but, in general, it is out of the question. Leeches applied to the part, are frequently productive of very great alleviation; and it is a great comfort, in general, to apply an evaporating lotion;—not cold, but tepid. A spirituous lotion thus tepid, does not produce a chilly effect. While these remedies are being employed, the diet should be scanty.

When the paroxysm is over (and it need never last long if treated in this way), friction of the parts is always found useful;—rubbing them with a flesh-brush, or the hand, and some salt-and-water, or similar stimulants. Sometimes it is necessary to give wine, or mild tonics, to relieve the languor that is left; but it is by no means *always* necessary. Occasionally, from the great severity of the pain, opiates may be required; but it is necessary to use the antiphlogistic measures that I mentioned.<sup>b</sup> If all this be done, and the patient's life is continued, the disease becomes comparatively trifling. I say "comparatively;" because it is always more or less painful. But it is not nearly so painful as it would be, if patients wrapped up their

<sup>a</sup> "Vinum Colchici."

<sup>b</sup> See the previous Paragraph.

limbs in flannel; took no colchicum; and, in the intervals of the disease, indulged in every absurd way they could.

*Application of Cold.*—It is dangerous to apply cold to the parts, during an attack of gout. Some have done it; and Harvey, who discovered the circulation of the blood, was accustomed (when an attack came on) to plunge his feet in a pail of cold water. I know persons that do this; but no medical man is justified in recommending it; for it has frequently happened that some disease has suddenly begun within. There has been apoplexy induced; or violent gastrodynia; or an affection of the heart; and the patient has died very shortly. If the patient chooses to do it on his own risk, he may: but he ought to be warned of the consequences by his medical friend.

Gout is a disease which it is not easy to eradicate; but, by the employment of colchicum, the disease is rendered much less violent than it was a few years ago. Formerly colchicum was employed with great success; and then it was forgotten entirely, till within a very few years ago. When I was a student, no one thought of exhibiting colchicum, in any form. It was only spoken of as a thing once used;—as an uncertain diuretic, and a violent purgative; and it was thought that it would be better, if it were expunged from the *Materia Medica*. I mentioned the *wine* of colchicum;<sup>a</sup> but some give the powder, in doses of five grains, every four or six hours; and some give the “acetum colchici.”

## CHAPTER II.

### RHEUMATISM.

*Definition.*—The next disease which I will mention, is nearly allied, in many particulars, to gout; and is called “rheumatism.” As “gout” is named from the idea of the dropping of morbid fluid,<sup>b</sup> so “rheumatism” is named from a similar idea;—the term being derived from the Greek word *ρευματιζω* (from *ρεω*, to flow). It is said that gout and rheumatism were not accurately distinguished from each other, till the year 1642;—both of them passing under the name of “arthritis.” Bellonius, who was a physician that suffered much from rheumatism, is said to have been the first that made an accurate distinction.

*Symptoms of the acute form.*—Rheumatism may occur in an *active*, or in a dull *passive* form; and the two varieties require very opposite treatment. In the *active* form of rheumatism,—that which is commonly called “*acute* rheumatism,”—there is heat, pain, and (in most instances) a swelling of the joints. These are not the *smaller* joints, as is the case in gout;<sup>c</sup> but the *large* ones; in general the wrists, the ankles, the elbows, the knees, the shoulders, and the hips. When these parts are affected with it, there is pain; but nothing of that violent kind which occurs in gout;—as if a dog were gnawing the joint.<sup>b</sup> It is as violent as a patient could wish it to be; but by no means so horrid as gout. The parts are generally hot and red; and frequently, from the pain being situated in the theca of the tendons, I have seen red streaks running in the situation of the tendons. There is generally swelling and puffiness in some part. Usually, there is feverishness, pyrexia, and a quick pulse. The pulse is not hard; but, in general, full and soft. The tongue is not foul and dry, but (in general) very white; and the urine is high-coloured, and deposits a lateritious sediment.

*Diagnosis from Gout.*—This disease does not, like gout, begin particularly in the night;<sup>b</sup> but invades at any time; and it does not come on at any particular season of the year. It arises from an evident exciting cause; and therefore it may come

<sup>a</sup> See Page 1012.

<sup>b</sup> See Page 1008.

<sup>c</sup> See Page 1009.

on at any time. It does not confine itself to one joint particularly; but leaves one and goes to another; and it will attack two or three at the same time. There is a shifting about;—it migrates in the most singular manner. Not only is there heat and an increased temperature, but heat generally makes the patient worse. Usually, too, there is profuse sweating; and the perspired fluid is often exceedingly sour to the smell. When the disease goes off, the parts do not desquamate and itch,—as they do after gout; but they merely cease to be hot, cease to swell, and cease to be inflamed.

*The Chronic Form.*—This is the usual state of things when the disease begins suddenly as an *acute* disease; but a similar state of things occurs in the *chronic* form. When the disease has lasted a twelvemonth, the parts are still hot, swollen, and painful; and the pain is increased if heat be applied. We find the same symptoms as in the acute affection; only they are less violent. In general, however, the sweating does not continue; for after the disease has lasted a few weeks, this symptom ceases; and the patient, perhaps, forgets it. It is sometimes a little difficult to make an accurate diagnosis;—at least it requires a little trouble; and it is well to ask about the sweating. If the disease have been acute rheumatism at first, there has been sweating; at least, it is unusual for a person not to sweat at the beginning of the disease.

*Not confined to the Joints.*—Although the joints are the parts particularly affected, yet persons frequently have the disease in the back; and then it is called “lumbago.”<sup>a</sup> Frequently it occurs in the back of the neck; and then the patient is said to have a “crick in the neck.” It may affect the face; and, indeed, it may affect almost any part of the body, where there are fibrous membranes, aponeuroses, ligaments, tendons, or (perhaps) muscles. There is no danger whatever from this disease, except from one circumstance;—which is, that the membranes within the chest (the pericardium and the pleura) are liable to be affected. They are sometimes attacked during the disease; and when the latter has suddenly ceased, or has gone off gradually, inflammation within sometimes takes place. This internal inflammation will occur at all periods, and in all possible circumstances; but it most frequently takes place about the time of puberty, and in young adults; so that, in acute rheumatism, we should never omit observing the state of the chest;—just as, in the case of an obstruction of the bowels, it is right to ascertain whether there is a hernia or not.<sup>b</sup> Now and then, inflammation occurs within the head, and phrenitis is set up; but that is rare; whereas inflammation of the pleura and pericardium, particularly the latter, is very common.

*Atonic Rheumatism.*—The *active* form of the disease, I mentioned, may be either acute or chronic.<sup>c</sup> The chronic form *may* have active symptoms; but very frequently it has not;—the parts are not hotter than they ought to be; but, on the contrary, are relieved by heat. This is sometimes the case in the *acute* form of the disease;—that is to say, it occasionally happens that persons, when they are first attacked with rheumatism, have no heat;—the pain is not aggravated by heat; but the parts are cold, and are the better for the application of heat. It is generally, however, in the *chronic* form of the disease, that the parts fall into this state of atony.

*Rheumatalgia.*—The disease sometimes appears to consist of little more than violent pain. Sometimes people complain of pain apparently in the muscles; but it may be situated in the aponeuroses over the muscles. There is simply pain on motion;—a pain not at all increased on pressure; and there is no swelling. This form of the disease has been called “rheumatalgia.” I do not know the necessity for giving it this name. Although rheumatism generally affects the fibrous membranes, yet sometimes it apparently affects the muscular fibres; and sometimes it appears to affect the nerves, or their covering; so that it will distinctly run down the sciatic nerve; though it is most frequently seen in the nerves of the face. I mentioned, when speaking of “tic douloureux,” that sometimes, besides the genuine

<sup>a</sup> From “lumbus,” the loin.

<sup>b</sup> See Page 914.

<sup>c</sup> See Page 1013.

form of that disease, we have another affection called "*rheumatic neuralgia*," which is easily cured.<sup>a</sup> When rheumatism affects the nerves, it clearly exists in their course, and then it frequently assumes an intermittent form. This is particularly the case in the head.

*Sometimes Intermittent.*—Rheumatism is sometimes intermittent, when it does not affect the nerves particularly, but when it affects aponeuroses; and this form of the disease most frequently attacks the head. In this case it usually affects one-half of the organ; and the pain generally comes on in the evening, about six o'clock; and continues, very violently, for a few hours. Occasionally, when it is intermittent in this way, the parts are hot, swollen, and throb, and the eyes water. But, in other cases, this is not felt; and the patient is all the better for wrapping up the head in a flannel petticoat. This is done among the lower orders; and with very good effect.

*Thickening of the affected parts.*—Occasionally the parts, when long affected with the disease, become thickened. We may have considerable thickening of the joints. The small joints of the fingers will throb, from time to time; and the patient will become a cripple, in consequence of the joints being inflexible;—just as in the case of gout.<sup>b</sup>

*Rheumatic Gout.*—As *gout* generally affects the *small*, and *rheumatism* the *large* joints, if rheumatism should affect the *small* joints, it is usually termed "*rheumatic gout*." Not that it is a combination of the two; though it sometimes may be. We may have the same appearances both from gout and from rheumatism.<sup>c</sup>

*Exciting Cause.*—There is, I believe, but one exciting cause of the disease; and that is the application of cold, or cold and wet; more especially if the patient be fatigued. I do not know that I ever saw a case, in the whole course of my life, that arose from any other circumstance.

*Terminations.*—I mentioned before,—when speaking of inflammation generally,—that rheumatism does not terminate in suppuration.<sup>b</sup> If suppuration occur, it must arise from another inflammation being accidentally present, or being excited by it. Neither does it terminate in mortification. There is sometimes effusion into the joints;—a considerable secretion of synovia or of fluid in the bursæ; and sometimes in the tendons. The parts may become rigid; and then, sometimes, mortification has been the consequence.

*Occurs in Infants.*—Rheumatism will occur in infants, as well as in old people; and this is worth knowing. I have seen many cases of the disease in very young children;—a circumstance very likely to be passed over. I have also seen disease of the heart in very young children;—as a consequence of pericarditis excited by this disease.

*Pathology of Rheumatism.*—[As certain forms of fever and inflammation are always accompanied by more or less of derangement of the assimilating processes, both primary and secondary; and such forms of fever and inflammation are not only preceded by long-continued derangements of the primary digestive processes, but frequently have their origin in such primary derangements; we<sup>e</sup> may perhaps be allowed to assume, that *some* diseases to which we apply the terms "*fever*" and "*inflammation*," are (*practically speaking*, at least) only severer derange-

<sup>a</sup> See Page 655.

<sup>b</sup> See Page 1009.

<sup>c</sup> When the lactic and lithic acids are developed together (as they may be, and often are), the phenomena may be supposed to show, that the mal-assimilation involves both the gelatinous and albuminous textures; and that the accompanying disease partakes of a mixed character; or, in fact, constitutes what is not improperly termed "*rheumatic gout*;"—a form of disease which, as every one knows, is usually of a much more deep-seated and obstinate character, than either gout or rheumatism alone. According to these views, therefore, the lactic and lithic acids, considered with reference to rheumatism and gout, may be regarded somewhat in the light of *materies morborum*; or, strictly speaking, the undue presence of these acids in the urine or elsewhere, in certain circumstances, may be viewed as indices of the existence of certain diseased actions going on in the primary tissues of the body; and which are known by the names of "*rheumatism*" and "*gout*."—*Prout, on Stomach and Urinary Diseases. Book 1; Chapter 3; Section 3; Subdivision 4. (Third Edition; Pages 210 and 211.)*

<sup>d</sup> Dr. Prout.

ments of the secondary assimilating processes, modified by the peculiar nature of the organs or textures in which such derangements exist;—inferences that will enable us to explain the principles on which derangements of the *primary* assimilating processes, predispose to those peculiar derangements of the *secondary* processes which we consider to be nearly connected, if not identical, with those forms of fever and inflammation usually denominated “intermittent fevers,” “rheumatism,” and “neuralgia;” on each of which affections we shall make a few remarks.

The exciting cause of the diseases just mentioned, is generally admitted to be *malaria*; and, if viewed abstractedly, and with reference to their specific nature, it is probable that malaria is the *only* exciting cause of these diseases. These diseases, however, are so generally associated with other diseases, arising from other exciting causes, that we rarely see them in their simple condition; moreover, diseases (as hectic, &c.) simulating them in many respects, are produced by other exciting causes than malaria; so that it often becomes a work of great difficulty, or even of impossibility, to distinguish one disease from another, and, consequently, to refer each exactly to its true exciting cause. How malaria acts in producing ague, rheumatism, and neuralgia, we do not know; but every one who has observed these diseases attentively, will probably admit, that the derangements of the assimilating organs constitute one of the first perceptible links in the series of symptoms; and, moreover, that these derangements of the assimilating organs are usually accompanied by the presence of great acidity in all parts of the system. Thus, in ague and rheumatism, during the sweating stages of the paroxysms, immense quantities of acid (chiefly of lactic acid) are thrown off by the skin; and sometimes by the kidneys. In these cases the saliva is commonly acid; and, in the severe and malignant diseases of this type,—occurring in tropical climates,—not only the saliva, but the whole assimilating organs, and even the blood itself circulating in these organs, have been observed to be in an acid condition. Thus, the dark-coloured fluid ejected from the stomach in yellow fever, and some other analogous diseases, appears to owe its colour solely to the presence of blood, which has been blackened by the large quantity of (lactic?) acid present; and which blood and acid must have been thrown off together, from the unnatural fluids circulating in the vessels of the stomach itself. Now, the presence of so much lactic acid cannot be accounted for, except on the supposition that a certain portion of what ought to constitute, or actually has constituted, the albuminous (or, rather, gelatinous) parts of the system, is decomposed or destroyed; and—as gelatinous and albuminous matters or textures cannot be converted into lactic acid alone—that, consequently, other unnatural and probably poisonous principles are developed in conjunction with the lactic acid; to which in part, as well as to the lactic acid, many of the secondary consequences of malassimilation are to be referred. In other words, the alimentary matters, which ought to be converted into albumen, by the primary assimilating organs; and the albuminous matters of the blood—which, in the secondary assimilating processes, ought to be converted into the living gelatinous and albuminous tissues—are, by the deficient or disordered operations of the vital processes, converted (in a greater or less degree) into lactic acid, and other unnatural combinations.

Such, then, are the conditions of the assimilating processes, which we<sup>a</sup> conceive to exist in the classes of disease we are now considering; the next question is—What constitutes the difference between ague, rheumatism, and neuralgia, when the cause and general conditions of the system in these affections are assumed to be the same? If our assumption be correct, the only answer of which this inquiry appears to admit is, that the circumstances constituting the varieties in question are—difference in the degree in which the same organs are affected; or differences in the seat of disease or organs affected; or, what is most likely, a combination of both these kinds of differences.

With respect to difference in *degree*, we do not think that this cause alone is sufficient to account for the varied character of the diseases in question. It is ad-

<sup>a</sup> Dr. Prout.

mitted, indeed, that difference in degree will, by causing the affection to be generally spread over the system, considerably modify the symptoms; but, unless specific organs be actually involved, there can hardly be supposed to be any difference in the *kind* of the disease. We are, therefore, driven to the conclusion, that these different forms of disease arise from derangements in the secondary assimilating processes proper to different tissues or structures. In rheumatism, the same derangements, to a less extent, appear to exist in the primary assimilating organs; but, in this case, the secondary assimilating processes, by which the gelatinous portion of the muscular system and its appendages is produced and maintained, may be supposed to be more especially implicated; and the loss of power, and the great degree of pain usually present in rheumatism, may be referred to the disorder of the numerous nerves of motion and of sense; which, as well as the fibrinous portion of the muscles, are likewise necessarily affected by the derangements. Moreover, on these suppositions, we may explain the formation of the large quantities of lactic acid usually present in rheumatic affections; as well as the swelling, &c.; for, as all the organs are more or less involved, and their functions paralyzed, not only imperfect assimilation takes place in the part affected; but the apparatus destined to remove from the scene of operation matters which are unfitted, or no longer useful, likewise ceases to act; and hence such unfitted and useless matters accumulate, and cause swelling in the part affected.<sup>a]</sup>

*Treatment of the Acute Form.*—Whether the affection be acute or chronic, the treatment should be exactly the same. We have only to make two distinctions;—to ascertain whether it is the inflammatory form of the disease;—whether the parts are hotter than they should be, and heat does *harm*; or whether the parts are *cooler* than they should be, and heat does *good*. In the one case, antiphlogistic measures will be required; and in the other stimulants.

*Blood-letting.*—Sometimes, where the patient is plethoric, it is advisable to take away blood from the arm; and we shall find it buffed and cupped. But there is no danger from that circumstance; for if we go on bleeding, we may find the blood buffed and cupped, till we have got nearly all the blood out of the body. But venesection is not always required. Free *local* bleeding generally answers better; but there is no objection to *general* bleeding, if the strength will allow it; and if several large joints be affected, it will be *better* than local bleeding.

*Cold Applications.*—With respect to the parts themselves,—whether we apply leeches, or cupping, or not,—we shall find it of great use to apply cold water or cold lotions, as long as the temperature is higher than it ought to be, and they feel comfortable to the patient. There is no danger in applying cold, with these limitations. If the patient should be timid, and yet long for cold evaporating lotions, they may be applied tepid (as in the case of gout<sup>b</sup>); but I never saw injury arise from cold in rheumatism, where the parts were hotter than they should be, and the patient felt hot.

*Colchicum and Mercury.*—The two best internal medicines are, without doubt, colchicum and mercury. Colchicum here, as in the case of gout, generally does no good till it purges;<sup>b</sup> and when once it purges the patient thoroughly, the disease usually gives way. It should be given in the same way as in gout;<sup>b</sup>—that is to say, with niagnesia; that it may produce its effect as speedily as possible. As soon as it purges, it is right to desist; and also as soon as its effect ceases. If we give a dose of hydrocyanic acid with the colchicum, it is better retained by the stomach. We may exhibit one, two, or three minims of the acid. But, every now and then, we shall find obstinate cases, which will not easily give way; although the greater part of them do; and then it is a pity to go on with the colchicum. We had better exhibit mercury,<sup>c</sup> and get the mouth tender. If we do this, in the first instance, instead of giving colchicum, the success is about the same. Colchicum may gripe, and mercury may make the mouth sore;—so that we may not be able to continue them. We may then leave off the one (whichever it may be), and exhibit the other;

<sup>a</sup> Dr. Prout, on Stomach and Urinary Diseases. Book 1; Chapter 2; Section 3; Sub-division 3. (Third Edition; Pages 80 to 83.)

<sup>b</sup> See Page 1012.

or if we begin with one of them first, and find it does no good, then we may exhibit the other.

*Bark.*—As soon as the inflammatory symptoms have gone down, and the patient has been properly evacuated, many give bark and quina. It has been said that bark is a safe and good remedy even in active inflammatory rheumatism; but we do not find, in Haygarth's work, any authority for such practice. We find, in his book, accounts of the successful treatment of rheumatism by bark; but then it was not till he had evacuated the patient upwards and downwards, and employed the antiphlogistic plan. After that, it is said that bark prevented the disease from recurring. I have not had occasion to use that medicine; for I have found the disease give way under the treatment I have mentioned.<sup>a</sup>

*Narcotics.*—It may be right to give narcotics, in order to produce ease; and a full dose of opium may be proper at night. There is no harm in it, provided we adopt antiphlogistic measures;—provided we bleed as far as bleeding is indicated, purge the patient well, and apply cold.

*Treatment of the Chronic Form.*—Exactly the same treatment is proper in the chronic form of the disease, if there are inflammatory symptoms; but whether the disease be recent or chronic, if the parts are not in this condition, an opposite plan should be adopted; and it is right to stimulate the parts. In this case, friction is an excellent remedy; and we shall find the hot-bath (particularly the vapour-bath) very useful. If the patient find alleviation from warmth and stimulants of all kinds, or the parts are colder than they should be, then this plan should be put in practice. The hot-bath should be employed, not every other day, but every day; and sometimes it should be used, in cases of extreme coldness and extreme pain, twice a day. It is here that electricity is of use; as well as friction; together with stimulating washes, stimulating liniments, and croton-oil;—which is a good stimulant when applied externally, and does not purge when so employed. Tartar-emetic, and sometimes moxa, have been employed; but only, of course, in very severe cases.

*Acupuncture.*—It is in this description of the complaint, that we find acupuncture of great use.<sup>b</sup> It is only in the fleshy parts that we can introduce the needle.<sup>c</sup>

<sup>a</sup> See Page 1017.

<sup>b</sup> Much information on this subject will be learned from Dr. Elliotson's Paper on Acupuncture, in the "Cyclopædia of Practical Medicine." (Volume 1; Page 32.) We subjoin his observations on the term itself:—"The passing of a needle into the body, is termed *acupuncture* (from 'acus,' a needle; and 'pungo,' to prick). From forgetting that the word '*puncture*' has two significations,—that it is used to express both the wound and the act of making it,—some have termed the operation '*punctuation*.' But to subjoin the syllables '*ation*' to the word '*puncture*' or '*acupuncture*,' is as improper as to subjoin them to the words '*preparation*' and '*fabrication*,' each of which already ends in '*ation*,' and has a similar two-fold meaning. An exactly parallel error would be to say '*manufacturation*.'" Dr. Elliotson gave the plan an extensive trial in St. Thomas's Hospital; and has published the result of that trial, in the Thirteenth Volume of the "Medico-Chirurgical Transactions" (Page 467). Out of forty-two cases, thirty were cured.

<sup>c</sup> M. Bretonneau says, that he has passed needles into the cerebrum, cerebellum, heart, lungs, and stomach of sucking puppies,—through and through, in all directions,—with no sign of pain, nor with any particular effect; unless when too large a needle was thrust into the heart; and, in one instance of this, a little extravasation took place into the pericardium. So far from fearing to acupuncture the heart, Dr. Carraco would have us do so in the worst cases of asphyxia. He declares that, in the presence of several persons, he kept several kittens under cold water, till they were apparently dead,—stiff, motionless, frothing at the mouth, without pulsation of the heart, and regularly sinking to the bottom of the water, every time they were thrown in; that he passed a needle into the heart; that soon the needle began to be gently agitated, then rapidly so; and that one voluntary motion after another gradually took place, till life was fully re-established; and that the animals did as well afterwards, as if nothing had happened. Death, however, by acupuncture of the brain or spinal-marrow,—as a secret mode of infanticide,—is notorious in works on State Medicine. "Guy Patin," says Foderé, "relates that a midwife was executed at Paris, for having murdered several infants at the moment the head presented at the os uteri; by passing a long and very fine needle into the brain, through the temples or the fontanelles; into the nape of the neck; or into the heart or its large vessels. Alberti and Brendel quote similar examples. In the "Causes Célèbres" we read the horrible story of a woman who, towards the

I should never advise it to be put into tendons and joints; though I have seen such things done. In general, it is only in the fleshy parts,—such as the deltoid, the biceps, the gastrocnemius, the rectus, or the gluteus muscles,—that it is right to put them. The best mode is to roll them by pressing them between the fingers; and they will soon pass to the desired length. We may insert them an inch and a half in depth; and if the bone is in the way, as in the case of the os femoris, there is no harm in the needles coming upon it; though there is no use in it; but they may go as far. The success of the operation does not depend on the number of needles; but on the time they remain in. If it be comfortable to the patient, we may let them remain in a couple of hours; that is, as long as a patient can bear to be kept still. There is no pain worth notice when they are introduced; and when they are in, there is no pain at all. It should be done every day; and occasionally we find relief as soon as they are taken out the first time; but in other instances, not till they have been employed two or three times; or perhaps oftener than that. It is only where the parts are not hotter than they should be, that acupuncture is of any use. I never saw it do good when heat increased the pain. Acupuncture is not an absurd remedy. It is a *strong* one; but I am quite satisfied it is a real remedy, if it be properly applied.

*Mercury.*—In the *chronic* form of rheumatism, we find mercury of the same use as in an *acute* attack.<sup>a</sup> Whether the parts are hotter than they should be, or not, obstinate cases give way to mercury, when they will not yield to any other medicine. Nothing is more common than for persons who are the victims of chronic rheumatism (whether it be inflammatory or not), but who are suffering great pain,—more especially if the pain be worse at night,—to receive no benefit whatever, till they have undergone a course of mercury; and as soon as the mouth is sore, they will lose all the pain. Mercury appears equally useful in both kinds of rheumatism.

*Guaiacum.*—One of the best internal stimulants, in a case of this sort, is the ammoniated tincture of guaiacum.<sup>b</sup> Guaiacum is a stimulating diaphoretic, and is very useful in this form of rheumatism; though it is of no service in the *active* form of the complaint. The tincture made with aromatic spirit of ammonia,<sup>b</sup> produces great warmth; and the patient remains warm for a longer or a shorter time. This is a medicine that may be given in various doses. Some persons are made hot with thirty drops; but others will take a drachm; and I have seen some who have taken six drachms, three or four times a day. There is no rule for it; but we should begin with half a drachm; and, as long as the patient is not warmed by it, and does not find it irritate him, we may increase it. Sometimes the warmth will last for one, two, or three hours; and, from a proper course of it, we shall find great alleviation. Sometimes it purges; sometimes it irritates the skin, and produces the nettle-rash; but when internal stimulants are necessary in rheumatism, I think this is one of the best.

*Diet.*—In the chronic form of the complaint, it is often necessary to support the patient well;—to give him wine, and nourish him assiduously.

*Arsenic.*—Arsenic has an excellent effect in this form of the disease, where the joints become cold. It frequently requires to be well persevered in; and (just like colchicum) it is borne by the stomach infinitely better, if we give prussic acid a little before it, or at the same time.<sup>a</sup> Arsenic is a medicine which is much disposed to irritate the stomach and bowels, and to produce gastritis; and, short of that, it frequently produces nausea and vomiting; but that may generally be prevented by prussic acid. The moment we find heat in the stomach and bowels, and pain on pressure, it should be omitted. We should ascertain this point every day; and when it occurs, the medicine should not be resumed till these symptoms

middle of the last century, made it her business to murder all the new-born infants that fell into her hands, by acupuncture,—practised at the top of the vertebral column, or in the brain;—with the sole intention, as she told the judges, of peopling heaven more and more.

—*Elliotson on Acupuncture, in the "Cyclopædia of Practical Medicine." Volume 1; Page 34.*

<sup>a</sup> See Page 1017.

<sup>b</sup> The "Tinctura Guaiaci Composita."

have gone off. Arsenic also produces soreness of the eyes, and redness of the throat; and when any of these symptoms arise, we must desist from exhibiting the medicine; and not resume it till they are gone off. There is no particular rule for the dose. It is best to begin with two or three minims; and, as long as it is borne without doing the patient any harm, we may increase it. I have known cases where thirteen or fourteen minims were borne; but that is a large dose. In general, seven or eight minims are as much as can be given. I do not know that there is any danger in the œdema induced by the medicine; but it shows that it acts on the body, and therefore it is better to desist. With regard to the gastritic affection, that would be dangerous if the arsenic were continued; but, with a careful practitioner, no danger can arise from this remedy. In the chronic form of the disease, blisters, setons, and moxæ may be of use;—just as in any other chronic inflammation.

*Bark.*—If the disease assume an intermittent form, we must treat it (in some measure) as intermittent fever.<sup>a</sup> We must give a large dose of quinia or bark, either just before a paroxysm is expected, or afterwards; and smaller doses at intervals.<sup>b</sup> Or we may employ arsenic.<sup>c</sup>

• *Stramonium.*—When rheumatism affects the face, a large dose of some narcotic, given just when the paroxysm is about to begin, often acts like a charm. It is an excellent plan to give a dose of stramonium, at the time the pain is coming on, and to repeat it in two or three hours. A large dose is generally required; and therefore, in the case of an adult, it is better to give a grain. In two or three hours, if there be no alleviation of the pain, and no affection of the head, we may repeat the dose. Sometimes the pain will not cease, till we have exhibited two or three doses; but I do not know more than one or two cases, in which this plan failed. It is certainly one of the best we can adopt. The ill effects of stramonium (as I before mentioned<sup>d</sup>) are dimness of sight, great thirst, and dryness of the throat; but these are not at all dangerous symptoms. The most unpleasant symptom is an affection of the head, drowsiness, giddiness, or delirium. I have frequently seen these induced, and then go away after a few hours; but if there be any hazard, an emetic may be had recourse to. If, however, we increase the dose slowly, this effect need hardly ever occur.

CURLING ON THE TESTIS AND SPERMATIC CORD.  
A PRACTICAL TREATISE  
ON THE  
DISEASES OF THE TESTIS,  
AND OF THE  
SPERMATIC CORD AND SCROTUM.

BY J. B. CURLING,

Lecturer on Surgery and Assistant Surgeon to the London Hospital, and Author of  
"A Treatise on Tetanus."

EDITED BY P. B. GODDARD, M. D.,

Demonstrator of Anatomy in the University of Pennsylvania.

---

"Mr. Curling has been at great pains to collect correct and useful information on the diseases of the testis from all the best sources, and his work must be allowed to be the fullest and most correct systematic treatise on the subject extant. The illustrations with which the volume is accompanied cannot fail to be extremely useful to the student of surgery and surgical pathology."—*Edinburgh Medical and Surg. Journal*.

"The revolutions produced by time in every fresh age are as remarkable in literature as in all other things. Our forefathers' heavy tomes, *multum in parvo* dictionaries, and "general treatises" have quite passed away, and a new class of works has taken their place. Such is the past and present. Of what the future will produce may be inferred from the writings of the young and rising men of our profession, who are now our cotemporaries. The advance will be important. At present the inclination amongst them is to devote the mind to some one object, in the study of which excellence may, with talent and perseverance, be ultimately attained. We have shown that spirit in exercise in a recent review of an original treatise on that previously ill-treated subject, the diseases of the skin, by M. E. Wilson; and we have another instance of it in the work of Mr. Curling, a diligent labourer, who has carefully collected every fact within his reach, relative to the diseases of the testis and spermatic cord, PRODUCING A VOLUME THAT MAY FOR MANY YEARS BE THE STANDARD WORK ON THOSE DISEASES. We shall conclude our notice with an extract relative to a new and promising method of treating varicose veins, and take leave of the volume by warmly recommending that it be added to the library of every surgeon."—*London Lancet*, August, 1843.

NOW COMPLETE IN ONE QUARTO VOLUME,

(SECOND EDITION,)

# QUAIN'S ANATOMICAL PLATES, FOR FIFTEEN DOLLARS.

---

## A SERIES OF ANATOMICAL PLATES,

With References and Physiological Comments, illustrating the structure of the different parts of the Human Body. EDITED BY

JONES QUAIN, M. D., *Member of the Senate of the University of London.*

W. J. ERASMUS WILSON, *Lecturer on Anatomy and Physiology at the Middlesex Hospital.*

With notes and Additions by JOSEPH PANCOAST, M. D., Professor of Anatomy in the Jefferson Medical College of Philadelphia, Surgeon to the Philadelphia Hospital, &c. &c.

The Plates are accompanied by letterpress, containing detailed references to the various objects delineated. But with a view to render them intelligible to a greater number of persons, a running commentary on each plate is given, stating in general terms, and divested, as far as can be, of all technicality, the uses and purposes which the different objects serve in the animal economy. The work consists of the following Divisions:

THE MUSCLES OF THE HUMAN BODY; *Fifty-one Plates.*—THE VESSELS OF THE HUMAN BODY; *Fifty Plates.*—THE NERVES OF THE HUMAN BODY; *Thirty-eight Plates.*—THE VISCERA OF THE HUMAN BODY, including the Organs of Digestion, Respiration, Secretion and Excretion; *Thirty-two Plates.*—THE BONES AND LIGAMENTS; *Thirty Plates.*

TERMS OF PUBLICATION.—This work is now complete in one splendid Royal Quarto Volume of *four hundred and fifty* pages of Letterpress Description and *two hundred splendidly engraved Plates*, containing *seven hundred and twenty-six* figures, and executed with the greatest accuracy, under the supervision of Professor PANCOAST. The Price, neatly bound in Full Cloth, and Lettered, is FIFTEEN DOLLARS a copy, payable on delivery.

Even in these days of cheap literature, no work has been offered to the Public on such moderate terms, and it is only by an extremely large sale that the publishers can hope to be repaid for their great expenditure.

Although the publishers deem any further remarks unnecessary, they cannot refrain from requesting the gentlemen of the Medical Profession to compare the Work, both as to price and style of execution, with any other that has appeared in this country, feeling assured that such comparison will prove the truth of their remark, that it is the CHEAPEST WORK EVER OFFERED TO THE AMERICAN PUBLIC.

 Persons desirous of subscribing to this work are requested to address CAREY & HART, Publishers, Philadelphia, (post paid,) enclosing FIFTEEN DOLLARS.

# COMPANION TO QUAIN'S ANATOMY.

---

## OPERATIVE SURGERY;

OR,

A DESCRIPTION AND DEMONSTRATION OF THE VARIOUS PROCESSES OF THE ART;

INCLUDING ALL THE NEW OPERATIONS, AND EXHIBITING THE STATE OF SURGICAL SCIENCE

IN ITS PRESENT ADVANCED CONDITION: WITH SEVENTY PLATES, COMPRISING

UPWARDS OF ONE HUNDRED AND FIFTY SEPARATE ILLUSTRATIONS.

By JOSEPH PANCOAST, M. D.,

*Professor of General, Descriptive, and Surgical Anatomy in Jefferson Medical College, Philadelphia;*

*Lecturer on Clinical Surgery at the Philadelphia Hospital, &c. &c.*

### TERMS OF PUBLICATION:

The work will be completed in one splendid Royal Quarto Volume of from 200 to 250 Pages of Letterpress Description, and about EIGHTY SPLENDIDLY EXECUTED PLATES, many of which will contain several Figures, and will be executed with the greatest care, by P. S. Duval, under the direction of PROFESSOR PANCOAST. The Price of the work, neatly bound in cloth, lettered, will be TEN DOLLARS a copy, payable on delivery. As specimens of both letterpress and plates can be had on application, it is of course unnecessary for the publishers to say more than that the entire work will be found to correspond in every respect with the specimens.

CAREY & HART, Publishers.

 Persons desirous of subscribing to this work are requested to address CAREY & HART, Publishers, Philadelphia, (post paid,) enclosing Ten Dollars.

## WAGNER'S PHYSIOLOGY,

TRANSLATED FROM THE GERMAN.

TO WHICH WILL BE ADDED NOTES AND REFERENCES

By SAMUEL JACKSON, M. D.,

PROFESSOR OF THE INSTITUTES OF MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

**GODDARD ON THE TEETH.**  

---

**THE**  
**ANATOMY, PHYSIOLOGY, AND DISEASES**  
OF THE  
**TEETH AND GUMS,**  
WITH THE MOST APPROVED METHODS OF TREATMENT, INCLUDING  
OPERATIONS, AND A GENERAL ACCOUNT OF THE METHOD  
OF MAKING AND SETTING ARTIFICIAL TEETH.

BY PAUL BECK GODDARD, M.D.,  
DEMONSTRATOR OF ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA.

In One Quarto Volume.

Illustrated by Thirty beautifully executed plates, each containing  
Numerous Figures, handsomely bound in Cloth Gilt—Price, \$6.

Uniform with “Quain’s Anatomy,” and “Pancoast’s Surgery.”—Price  
Six Dollars, full bound in cloth.

This work is designed to furnish the practical Dentist and country Physician with a full account of the *Anatomy, Physiology, and Pathology*, of the Teeth, with the remedies proper in each case. It also contains full directions for the making and setting of Artificial Teeth. The Anatomy contains an account of the microscopic structure, which has recently been so highly developed, and which throws much light on the changes produced by various agencies, chemical and mechanical. The *physiological* portion contains the description and development of the growth of the teeth, both temporary and permanent. The *Pathology* comprises the diseases of the teeth, with the appropriate treatment, including scaling, filing, plugging, extracting, &c., &c. The last portion is devoted to the making, colouring, and setting artificial teeth, particularly those known by the title of Incorruptible. The practical details included in the last section will be furnished by a Dentist who is thoroughly acquainted with his profession. The plates which illustrate every point of value or importance will be of the full quarto size, and in almost every instance will be from nature, and their execution of the best character.

The publishers refer with pleasure to “Quain’s Anatomical Plates,” to which the present volume is intended as a companion.

CAREY & HART WILL SHORTLY PUBLISH  
**A TREATISE**  
ON THE  
DISEASES OF THE GENITO-URINARY ORGANS,  
INCLUDING  
THE AFFECTIONS OF THE  
**KIDNEY, BLADDER, PROSTATE, AND URETHRA,**  
By MEREDITH CLYMER, M. D.,  
LECTURER ON THE INSTITUTES OF MEDICINE, PHYSICIAN TO THE PHILADELPHIA HOSPITAL,  
FELLOW OF THE COLLEGE OF PHYSICIANS, ETC. ETC.

**A WORK ON SURGICAL DISEASES.**

WITH ABOUT SEVENTY FINELY ENGRAVED PLATES,  
*Illustrative of the Pathology, and various Methods of Treatment.*

In one 4to. volume.

# PRINCIPLES AND PRACTICE OF MEDICINE:

By JOHN ELLIOTSON, M. D., F. R. S.

EDITED BY NATHANIEL ROGERS, M. D.,

AND

ALEXANDER COOPER LEE, Esq.

*From the Second London Edition, greatly enlarged and improved.*

Complete in One Volume.

WITH NOTES AND ADDITIONS ADAPTING IT TO THE UNITED STATES,

By THOMAS STEWARDSON, M. D.,

Physician to the Pennsylvania Hospital.

Among other additions THE AMERICAN EDITOR has introduced entirely new articles upon REMITTENT FEVER and YELLOW FEVER, as well as considerable additions to the article on Continued Fever.

## *From the Preface.*

When this work first appeared, it had to compete with several long established favourites, and to encounter some deeply rooted prejudices on the part of men who strongly dissented from Dr. Elliotson's views on certain subjects. In spite of these obstacles, however, its reception has been more flattering than we dared to anticipate. The first impression was rapidly exhausted, it became the favourite class-book in the majority of our medical schools; and even those who were formerly strongly prejudiced against it, have since acknowledged the practical information they have derived from its perusal. All this is highly satisfactory; and were any additional proof of its sterling worth required, it would be furnished by the fact that the Germans have published a translation.

In entering on the task of preparing for publication a second edition, we have been stimulated by the success of the first to fresh exertions, in order to render it (if possible) still more worthy of the approbation it has received. With a view to the accomplishment of this object, we have ventured on making certain additions and alterations; which, without materially increasing the size of the book, will (as we believe) materially enhance its value. Much care and discrimination were necessary in making these additions,—both as to the material to be selected, and the mode of its insertion: otherwise the book would have been injured, rather than improved. We have therefore been careful only to remedy obvious deficiencies, and to make such other additions as more recent researches had rendered necessary. The sources whence this supplementary matter has been taken are various; but we have of course been guided, to a great extent, by public opinion;—making our selections from those works which seemed best entitled to our confidence, from their general accuracy and soundness of doctrine. For the purpose of rendering these additions as useful as possible, it has been deemed advisable to insert them within brackets, in the text;—taking care, however, to preserve the continuity of the whole; and to acknowledge, in a foot-note, the source whence each quotation was derived. Some other illustrative extracts, often very interesting in a literary point of view, and all bearing on some medical observations in the text, have been inserted as foot-notes.

The alterations that have been made, though few, are such as has been dictated by a desire to consult the convenience of the reader. The subjects have been grouped together, in conformity with Dr. Elliotson's own views; and divided into parts, books, chapters and sections. Page-headings and side-titles have been introduced: which, together with a copious index, will (it is hoped) enable the reader to refer to any particular passage with perfect ease. We may also add, that the work has been printed with a smaller, though clear and distinct type;—for the purpose of enabling us to add about two hundred and fifty pages of new matter, without materially enhancing the size or price of his book.

### OPINIONS OF THE PRESS.

Almost every subject exhibits great research and acumen, original and comprehensive views, and an extensive acquaintance with Physiology, Pathology, and all the known resources of the healing art. Some affections which are scarcely noticed in other works (such as Glanders, Hay-Asthma, &c.) are also considered; and there is much interesting detail connected with these topics.

After a diligent perusal, we have formed the highest opinion of this edition of Dr. Elliotson's "Principles and Practice of Medicine." It is the most modern work on the subject; and is every way calculated to represent to foreigners the present state of practical medicine among the best practitioners of our country. We think it unnecessary to recommend it; because it will recommend itself, and command success by its own intrinsic merits.

The Editor, Dr. Rogers, has acquitted himself in a very admirable manner, and we cordially assent to all that he claims in his Preface. He also deserves the negative commendation of not encumbering the text with multifarious notes. Most readers prefer to judge and compare for themselves. We have only to add, that it forms a goodly volume, containing upwards of 1100 octavo pages, printed in a bold and clear type, and published at a very moderate price.—*Medico-Chirurgical Review*.

It is very gratifying to meet with a work replete with sound and valuable matter;—with golden rules of precept and practice, derived from the writer's long experience and observation; and in which all the resources of a well-cultivated mind are brought to bear upon and illustrate the subject to which its energies are addressed. Such a work is the one before us; in the production of which Dr. Elliotson has been induced to acquiesce, under the editorship of one who has proved himself well worthy of the office.

We find some excellent preliminary observations on the means by which the art of medicine is to be perfected; followed by a copious introductory discourse, calculated to be of great use to the student. Our author's exposition of inflammation is most excellent; and, though occupying upwards of eighty pages, we do not see a line we could "wish to blot." Immediately in connection with inflammation come hæmorrhage, profluvia, and dropsy; then change of structure, and new formations (as scirrhus, tubercles, cancer, &c.); which conduct us to those diseases termed by our author "universal:" as anæmia, chlorosis, scurvy, and fevers, (intermittent, remittent, and continued.) All these topics are expounded with first-rate ability; and betray, in every touch, the hand of a master. The details connected with malaria, as a cause of ague, of contagion, and as a source of continued fever, are particularly copious, interesting and important.

We regret that we have not space for copious extracts, from the vast mass of exceedingly important information contained in these pages; although we

are thus saved the predicament of selecting from so much that presents equal claims for insertion. The chapters on plithisis, and diseases of the heart, are worth the price of the entire volume; particularly since the editor has supplied, either by notes or appendix, the cream and substance—the *heart* (we may say)—of Dr. Elliotson's well known and highly esteemed work on the latter subject. Dr. Rogers has also furnished a synopsis of Cullen's "Nosology;" some physiological and toxicological tables, by the late Dr. Fletcher, extracts from Dr. Elliotson's "Physiology," &c.; and we cordially award him our meed of praise, for his skill, vigilance, and fidelity. On the whole, we have the highest opinion of its merits; and consider it decidedly the best, as it is the most recent work on the subject. As such, we predict for it a standard reputation; and a very extended sale among the cultivators of practical medicine. Such a work ought to be in the hands of every practitioner who desires to fulfil the grand purpose of his vocation—the diminution of "the thousand ills that flesh is heir to,"—that noble study which renders medicine what the ancients were wont to term it;—"*ars divina,—a heaven-descended art.*"—*Dublin Medical Press.*

It will be generally admitted, that to an extensive acquaintance with physiology and pathology, Dr. Elliotson unites the faculty of accurate diagnosis, and acute discrimination of the best methods of treating disease. Few, we think, will be disposed to question his zeal and activity as a physician, and as a teacher of the principles and practice of medicine; or the judicious views, philosophical deductions, and sound methods of treatment here developed. Almost every page teems with valuable information. Much praise is due to the editor, for the exemplary manner in which he has acquitted himself. He has not overloaded the text with superfluous notes; but has appended just so much as was necessary for the purpose of illustration, and to fill up some hiatus. He has also considerably improved the language. We strenuously recommend the work to all who feel interested in the advancement of Practical Medicine.—*London Medical Gazette.*

The author has been long honourably distinguished as standing in the foremost rank of those who have formed a corps of observation for the purpose of exploring the recesses in which those terrible foes of the human race, phthisis and its allies, had hitherto reigned in almost undisturbed dominion. His language is simple and nervous, and remarkably free from technicalities, and inflated epithets; while his style is of that pleasant, familiar kind—neither too bold, nor too florid—which accords well with the subject, and the occasion. The medical world is under great obligations to Dr. Rogers, for having undertaken the editorship of this work. He has evidently bestowed great pains in amending the text, correcting reporters' mistakes, and supplying deficiencies;—in every way proving himself a faithful Achates. We cannot entertain a doubt, that this work—embodying as it does, the mature experience of an able and accomplished physician—will be welcomed by all classes of the profession. We predict for it a wide circulation, and the warm encomium of every one who becomes possessed of it. Less than this will not be commensurate with its high deserts.—*Dublin Journal.*

The best work for the study of diseases is Elliotson's "Principles and Practice of Medicine, by Rogers and Lee."—*Lancet.*

We strenuously recommend the work to all who feel interested in the advancement of Practical Medicine.—*Mcd. Gaz.*

# ENCYCLOPEDIA OF CHEMISTRY.

NOW READY, No. 1, PRICE 25 CENTS,

## THE ENCYCLOPEDIA OF CHEMISTRY, THEORETICAL AND PRACTICAL.

PRESENTING A COMPLETE AND EXTENDED VIEW OF THE PRESENT STATE OF  
CHEMICAL SCIENCE, WITH ITS NUMEROUS AND IMPORTANT APPLICATIONS TO  
MEDICAL SCIENCE, AGRICULTURE, THE ARTS, AND MANUFACTURES.

BASED UPON THE PLAN OF THE

DICTIONARY OF CHEMISTRY, BY DR. URE; AND THE DICTIONARY OF  
THEORETICAL AND PRACTICAL CHEMISTRY, NOW PUBLISHING  
BY LIEBIG, POGGENDORF, WOEHLER, &c.

BY JAMES C. BOOTH,

Member of the American Philosophical Society, and of the Academy of Natural Sciences,  
Professor of Technical Chemistry in the Franklin Institute, and of Elementary  
Chemistry in the Philadelphia High School;

AND

MARTIN H. BOYE,

Member of the American Philosophical Society.

The facility for easy reference offered by the Dictionary, (rendering that form preferable to any other for works on science and the arts,) has induced the author to adopt it in the publication of an

### ENCYCLOPEDIA OF PRACTICAL AND THEORETICAL CHEMISTRY,

which, while it will embrace all the latest discoveries in the pure science of chemistry, shall at the same time exhibit the manifold applications of chemical principles and theories to every department of the useful arts.

The rapid advancement of chemical science in the path of discovery within a few years, has created a demand for treatises upon this subject which has not been fully answered by the several elementary works lately issued from the English press.

While these works must be mentioned with unqualified praise as text-books for the student of chemistry, it must at the same time be acknowledged that since they offer little more than an outline of the science, they cannot satisfy the thirst for more extended treatises, which may be employed as valuable works of reference by the advanced scholar, while their practical tendency shall enable the uninitiated to enter actively into the vast field of research.

THE ENCYCLOPEDIA OF CHEMISTRY is designed to meet the varied wants of  
THE STUDENT OF SCIENCE, THE PHYSICIAN, THE AGRICULTURIST, AND THE MANUFACTURER.

The first and second will find the whole theory of chemistry fully developed, as contained in the original essays of all the great and leading chemists, among whom we place BERZELIUS, LIEBIG, WOEHLER, ROSE, MITSCHERLICH, ZEISSE, &c., DUMAS, PELOUZE, FREMY, &c., GRAHAM, KANE, HARE, and many others in Europe, and in our own country. They will find all the important recent discoveries in *organic* and *inorganic chemistry*, and practical treatises on the several branches of analysis.

### THE SCIENCES OF MINERALOGY AND GEOLOGY

will receive their full share of attention, more especially in their chemical relations, and where they admit of such application.

It will be seen from the hasty sketch of the design of the work presented above, that it is intended as a complete

ENCYCLOPEDIA OF CHEMISTRY BOTH IN THEORY AND PRACTICE, and that while the pure theoretic nomenclature will be adopted in the one part, the second shall be so developed as to bring it within the reach of those not fully conversant with chemical principles.

### TERMS OF PUBLICATION.

The work will appear in semi-monthly numbers, and in addition to numerous woodcuts, will contain many beautifully engraved plates, and will be completed in Twenty Numbers, at 25 cents each.

CAREY & HART, PUBLISHERS.
